THE EDITORS

SIR DONALD MACKENZIE WALLACE, K.C.I.E., K.C.V.O.

ARTHUR T. HADLEY, LL.D., PRESIDENT OF YALE.

HUGH CHISHOLM, B.A. (FORMERLY SCHOLAR OF C.C.C. OXFORD)

THE DEPARTMENTAL EDITORS

FOR LAW AND GOVERNMENT:
THE HON. SIR JOHN SCOTT, K.C.M.G., Deputy Judge-Advocate-General.

FOR MILITARY AFFAIRS:
SIR GEORGE SYDENHAM CLARKE, K.C.M.G., F.R.S.

FOR MEDICAL SCIENCE:
D. NOEL PATON, M.D., B.SC., F.R.C.P.ED.

FOR THEOLOGY:
REV. W. E. COLLINS, M.A., Prof. of Ecclesiastical Hist. at King's Coll., Lond.

FOR MINING:
HENRY M. HOWE, A.M., Prof. of Metallurgy at Columbia University.

FOR BOTANY:
D. H. SCOTT, M.A., PH.D., F.R.S., Hon. Keeper, Jodrell Laboratory, Kew.

FOR GEOGRAPHY AND STATISTICS:
J. SCOTT KELTIE, F.S.S., F.S.A.SCOT., LL.D., Sec. Roy. Geog. Soc.

FOR ASTRONOMY:
SIMON NEWCOMB, PH.D., LL.D.

FOR MATHEMATICS:
JOSEPH LARMOR, M.A., D.SC., SEC.R.S., University Lecturer in Mathematics, Cambridge.

FOR ELECTRICITY:
J. A. FLEMING, M.A., D.SC., F.R.S., Prof. of Electrical Engineering, Univ. Coll., London.

FOR ART:
M. H. SPIELMANN, Editor of the *Magazine of Art.*

FOR ZOOLOGY:
G. HERBERT FOWLER, PH.D.

FOR NAVAL AFFAIRS:
JAS. RICHARD THURSFIELD, M.A.

FOR BIOGRAPHY:
RICHARD GARNETT, C.B., LL.D.

FOR LITERATURE:
EDMUND GOSSE, LL.D.

FOR ECONOMICS:
WYNNARD HOOPER, M.A.

FOR RAILWAYS:
MAJOR HENRY G. PROUT, Editor of *Railroad Gazette*, N.Y.

FOR MUSIC:
J. A. FULLER MAITLAND, M.A., F.S.A.

FOR GAMES AND SPORTS:
ALFRED WATSON, Editor of the *Badminton Library.*

PREFATORY ESSAY.

THE FUNCTION OF SCIENCE IN THE MODERN STATE.[1]

By Karl Pearson.

I. *Science and the Structure of the Modern State.*

BEFORE the second half of the 19th century a true theory of the state was impossible. A sound idea of mankind as but one among many types of life, even if the highest type, had hardly entered men's minds—they were accustomed to contrast "nature" and "man." But had it entered, they knew so little about the laws governing any form of life, that they would not have gained much by extending the little known to man. Not till the publication of Darwin's epoch-making works was a real appreciation of man's position in the evolution of living forms possible, and with this appreciation all the old theories of the state became practically idle—landmarks only in the study, ever-interesting to man, of the history of human thoughts and theories. A complete revolution was wrought in the ideas of those who read and understood Darwin, both as to the nature of the state and as to its functions. The theory of the state could no longer be treated from either the philosophical or the purely logistic standpoint. The state was the product of an historical evolution; the nation was a unity evolved by the struggle of one living type under the same laws as applied to other phases of life. The theory of the state became biological: one of the most complex and difficult branches of biology no doubt; but still it was a great step to remove this theory from philosophy—or even from metaphysics, as in the case of Hegel—and transfer it to its true class.

Biological theory of the state.

It is little wonder, perhaps, that the first investigators in this new field went widely astray. They extended without due thought fascinating biological hypotheses to the case of man. They found the struggle of individual against individual in many vital fields, and they extended the survival of the fitter as a governing principle to all individual life within human communities; they did not stay to inquire why and how communities had themselves come into existence; they neglected the suggestions of the hive and the herd, and reached (as in the cases of both Spencer and Huxley) fallacious conclusions as to the functions of the state and the sources of social conduct. In short, they over-emphasized the intra-racial struggle, and under-emphasized the inter-racial contest, as factors producing and developing the political and moral characteristics in man. Other state theorists, again, accepted without qualification some doctrine like that of panmixia, unproven or even disproven for the lower types of life, and heedlessly applied it to civilized man. Nor were these over-hasty conclusions to be entirely condemned: by the discovery of the doctrine of evolution by natural selection, an absolutely new country had been thrown open, with endless possibilities for thought and action. What wonder if publicists, with no

[1] It must be understood that this is the briefest sketch of a vast and all-important subject, where the writer has not been able at every turn to develop detailed plans, but only to outline suggestion and criticism.

sound biological training, indeed no scientific training whatever, rushed in with jubilation to be among the early settlers? What wonder that biologists, with small historical knowledge, even without intimate acquaintance with the exact social history of any human community for the briefest of periods, extended at once great vital principles beyond their legitimate limits?

We can scarcely be surprised that some false views as to man and the state were propounded under the new impetus, or that some mistakes were made even in social legislation. Reaction was certain to come, and the cycle was completed, as usual, by a German professor demonstrating all Darwinian theory to be snare and delusion.

Darwinian theory and man.

Let us then at the present moment take stock and see where we actually stand. The main principle of evolution by natural selection is based upon four factors:—(*a*) That characters are variable. (*b*) That characters are inherited. (*c*) That there is a selective death-rate, *i.e.*, that individuals possessing characters or combinations of characters in a higher or less degree than other individuals die, on the whole, sooner or later than the latter. (*d*) That those individuals who die early leave fewer offspring than those who die late. How far are these factors demonstrable truths in the case of civilized man?

(*a*) This is beyond question for both physique and intelligence in man.

(*b*) This is absolutely certain for both the mental and physical characters in man. Both these are sensibly inherited at the same rate and, further, with such a degree of intensity that three, or at most four, generations of selection will suffice to establish a race in man which will breed true to itself under a stable environment.

(*c*) By observations on the death-rate of relatives—*i.e.*, of groups of individuals possessing like characters or combinations of characters—it has been demonstrated that 50 to 80 per cent. of the deaths among mankind are selective.

(*d*) This has been statistically demonstrated for both sexes in Great Britain, America, and Australia.

We are forced, then, to the conclusion that the Darwinian theory in the case of mankind is a law and not a "plausible hypothesis." It is a different problem to measure the rate at which evolution works. What sensible modifications can be made within 200, or even 8000, years in a human race by evolution? Recent craniological investigations seem to show that, even within the shorter of these periods, such changes can occur in the shape of the skull of a single race that 50,000 years or less would suffice to have modified the cranium from a type which any modern anatomist would hesitate to call human. The argument is not that the human skull has always gone forward at this rate, but that it could do so under apparently quite ordinary conditions. In other words, the biologist's demand for time must not be looked upon as indefinitely exceeding what the geologist is prepared to grant.

Such is our modern stock-taking—a possibility of the work done between 1890 and 1902—of the relation of the Darwinian theory to man.

The international struggle for existence.

But if we only apply the principle that all life progresses by the struggle of individual against individual to the history of man, we find half the facts of both social and political history wholly unintelligible. We have missed the great point, that man has largely progressed because he is gregarious; we cannot describe on such a basis the evolution of morality, the origins of tribal customs, tribal worship, national institutions, national religions, and, ultimately, of the modern state. We might as well attempt, on the basis of the survival of the fitter individual, a satisfactory explanation of why Sir Harry Johnston's African ant gave forth, when trodden on, a most appalling stench, so skunk-like that the destroyer fled from the spot. The welfare of the whole has controlled in this case, as in others, the development of the individual. The community in its entirety is struggling against its vital and physical environments. As soon as we interpret the facts of history in the light of progress by inter-racial struggle, and only in a secondary manner by intra-racial competition, those facts become deeply suggestive and significant for our guidance. We see both Roman and Hebrew nations arising from very small beginnings by successful variations in tribal custom and belief. We no longer mourn over the apparent waste of power in the continuous wars of the small Greek communities: we see in that strife the probable source of their rapid progress

in intelligence and physique. Nay, modern Europe itself at once becomes the stage whereon the drama of evolution is being played out amid the hum of factories, the clash of armaments, and the buzz of youth in the playing-field and the lecture-room. History has painted for us the ever-present strife of nations: in the lower stages we see the victory of brute-force and of cunning; in somewhat higher stages we find the dominance of strength, valour, and discipline; at the present the factors of mastery are possession of material sources and the skill to turn them to account,—the copious store of knowledge, the power to increase it at will, and the intelligence to apply it for the national profit. The struggle of nations is the commonplace of history; but the realization that this struggle is a factor in human development,—that big battalions or an armada are not sufficient insurance for success in it, but that organization and intelligence in every function of national life are requisite for victory,—this is the special truth that dawned upon us at the end of the 19th century. Formerly territory was blindly seized, trade routes and commercial markets blindly opened or controlled, manufacturing processes and means of transit developed or not, according as they might seem profitable or not to individuals. The bearing of these things and a multitude of others—such as the physique of the nation, the skill of its craftsmen, the intelligence of its trade-leaders, the activity of its educators, the organization and preservation of its material resources—was unrecognized in their relation to national fitness for the international struggle. The politician could tell the nation that it must have more ships or more rifles for the national safety, or he could emphasize the importance of the "open door" for national welfare, but he did not provide for the intelligent building of the ships, the intelligent sighting of the rifles, the intelligent training of the merchants who were to enter the open door amid the great international crush to get inside. He did not see that ultimately the training of even the apparently most insignificant workers in the community, the fitness for its purpose of the simplest manufacturing or agricultural process, may be vital to a nation in the evenly balanced contest of modern civilization. To stand still—for a moment to depend only on the possession of material resources, of the existing trade routes, or of means of transit—is to lose points in the game. Where all are pressing forward, not to advance is to fall behind.

Factors of national success.

Let us consider for a moment some of the factors of national welfare. First, the physical powers of the nation—*vital*: its numbers and effective fertility, its health and sanitation, the energy, vigour, and absolute strength of individuals; *material*: mineral wealth, sources of mechanical energy, coal, oil, water power, water and rail transit, docks, coaling stations; *equipment*: power to seize and power to hold. Secondly, the mental powers of a nation—power to carry out mechanical work quickly and effectively; power to discover and power to imagine, to incite and to stimulate:—*morale* and patriotism; power to resist long strain, to avoid epochs of national hysteria, to follow for years definite policies with only future profit in view, to govern effectively, or ultimately assimilate divergent racial groups. On examination, each one of these and other factors of national efficiency will be found to require intelligent handling: they demand training and knowledge—science in its broadest sense—if the stability of the state is to be maintained and increased, if the nation is to contribute its full share to the total progress of human activity.

Trained intelligence at the basis of national fitness.

The future is to the nations which not only realize the international struggle in all fields of activity, but consciously develop all the factors of national efficiency with this end in view. This is the theory of national life which presents itself at the beginning of the 20th century. It connotes an immense development of the functions of science in both legislature and executive. It should lead to new conceptions of, and new scope for, patriotism, and a revised attitude towards state action and state service. Brute force, strength and bravery, material wealth, have in turn been dominant in the state; to-morrow will be marked by the dominance of intelligence. The most intelligent nations will be victorious in the struggle; and it befits each state that would be great to-morrow as well as to-day to educate and organize itself, from the statesmen at the top to the ploughboys and factory hands at the basis. In the future it will not be possible either to organize and lead a nation or to make a cheese effectively without training—without a knowledge of what science has to say about men or milk.

The education of the nation, from statesman to dairymaid, is a task of great magnitude—more especially in old countries, where the institutions have developed historically, and often preserved features of earlier periods, when other factors than intelligence were dominant in national life. On the other hand, the older nations possess traditions and divisions which are not without service as rough results of experience. Caste and class may be exaggerated so much that they do far more harm than good, but to a certain extent they may serve for differentiating workers within the community. The nation stands equally in need of its ploughmen, its craftsmen, its traders, its brain-workers, and its leaders; and it is desirable to have some preliminary classification of what work an individual is best suited for. While, on the one hand, it is most important that all capacity which will be of special social service in performing a particular function shall find that function within its reach, it is, on the other hand, not only undesirable, but impossible, to subject every individual in the nation to a test of fitness for every possible calling. With rough practical efficiency a man's work in life is settled by his caste or class. This is not so undesirable as it might at first sight appear; it is a largely unconscious differentiation of the nation into workers of different types, who marry within their caste, and—if we remember how few generations are needful for a special human group to breed true—thus preserve to a large extent their special usefulness. We need a net which will be widely cast to drag upwards, and a similar net to drag *downwards,* but the meshes of neither of these nets should be too small. It is cruel to the individual, it serves no social purpose, to drag a man of only moderate intellectual power from the hand-working to the brain-working group; yet this seems too often the result of the present system. If there be a moderately capable worker, the state should strive, in the first place, that he should be trained to better craftsmanship. Do not let it assume that he will turn out a Faraday because he shows some relative capacity. In at least nine cases out of ten disappointment will be in store for the state if it does. Let there be a ladder from class to class, and occupation to occupation, but let it not be a very easy ladder to climb; great ability will get up, and that is all that is socially advantageous. We have to remember, for example, that the middle class in England, which stands there for intellectual culture and brain-work, is the product of generations of selection from other classes and of in-marriage. A hundred men of this class, quite apart from training and tradition, will provide a greater percentage of men capable of doing brain-work, than a hundred men from the farming class, or a hundred craftsmen.[1] These in their turn (if we do not regard training and tradition, though there is no reason why we should not) will produce a larger proportion of men suited for colonists or for the workshop than the former, and for precisely the same reasons—long selection and in-marriage. Again, we assert, the gradation of the body social is not a mere historical anomaly; it is largely the result of long-continued selection, economically differentiating the community into classes roughly fitted to certain types of work. And here we reach the first fundamental principle in the education of a community: the education must be specialized for each individual class of workers—all intelligence must not be driven through the same mill. The system under which local colleges ape universities, polytechnics ape local colleges, night-schools ape polytechnics, and all think it the highest merit to get their students stamped with a degree of one kind or another, is an utterly fallacious one; it is educational chaos, and has not the slightest approach to that harmonious system of education differentiated to class-function and class-intelligence, which must be at the basis of national fitness, *i.e.*, the readiness of each group in the community to do its specialized work efficiently. Let there be a ladder then, that indisputable capacity may climb to the place where it is most wanted, but the nation needs that the great bulk of its members shall work at the same tasks as their forefathers, only with increased intelligence and more highly developed craftsmanship.

Significance of class and caste.

[1] The cry for "an easy ladder" is a most mistaken one, especially as long as any false feeling of gentility attaches to one or another class of workers. During the last few years the writer has come largely in contact with a number of young men and women whom the county councils up and down the country are educating at the national expense. These county council scholars are on the average not up to the mean middle-class intelligence. It is very rarely that one could not pick out for any given post better, often many better, middle-class candidates. In this case the meshes of the net are far too small: ten per cent. of the scholarships would have sufficed to procure the really capable men and women whom it was of social value to educate for intellectual pursuits. The rest want either the originality, the power of self-assertion, or the physique which would enable them to force their way forward in a new sphere. The bitterness of failure is upon those, who, scholarships ended, sink to usherdom in small private schools, or to second-rate draughtsmen in engineering works. Taught in true craft-schools, they might well have been leaders in their own class, instead of failures in another.

Make it easy for the Michael Faradays to climb, but only for such as he was; the increase of the intellectual proletariat is a sign not of efficiency but of chaos in national education.

Need of specialization in education.

If national education at the present day be a *sine quâ non* of national fitness for success in the world-struggle, it must none the less be a specialized education suited to develop the intelligence of each caste and class. Training is essential to a nation, but it must be specialized to each social activity, if it is to perform its function. How is this truth to be brought home to the statesmen, the permanent officials, or the politicians, who alone can bring order into educational chaos? The statesmen of the old school, blamelessly ignorant of the laws of national development, were inclined to look upon race-progress as due to mighty forces beyond human control, and thus to believe that executive and legislature could do little to make or mar national welfare. But as we learn to understand better the laws ruling living organisms, our appreciation of the factors in human history changes: man cannot modify the law of gravitation, but he can make its effects subserve his own ends; and this is equally true of the laws which rule organic and inorganic material.

Training of the statesman.

Unfortunately the training of the statesman himself is often sadly defective; he rarely stands at the summit of the knowledge of his day, or has the instinct to select his subordinates for real organizing power. In a democratic state the process by which the statesman is chosen is at best a risky one. His requirements are, first, ample private resources; secondly, power to impress a possibly well-meaning but largely ignorant democratic electorate; and lastly, ready debating power and personal influence on the somewhat narrow group, chiefly of his own type, which is to be found in the average representative assembly. There is no security in these requisites for a training in statecraft. The race-leaders and potential empire-builders rarely find their way into representative assemblies. The men who could organize a great national department, or even organize the nation itself, devote their energies to the building up of world-wide commercial enterprises to their own profit, or to the profit of a narrow circle. And when such men have convinced the world of their business capacity, of the shrewdness with which they can appreciate new ideas and forestall the future, they are already beyond their prime. They have no longer the inclination to learn the complex routine of parliamentary life, or the power to stand its physical strain. One of the most difficult problems for the democratic state is to make state service in its highest branches a career for such men in their youth, and thus allow the nation to exploit at once and directly their power of initiation and organization. Still more difficult, perhaps, is the selection of statesmen in the case of an oligarchy. The nation which bred and trained a specialized class of men solely for statesmanship would undoubtedly be best governed under such a true aristocracy. But in practice the existing false aristocracies fall far short of serving any such state function. There is no security that the dominant caste represents either the intelligence or the organizing power of the community. Even if the caste be based on wealth-accumulating power or state-service of ancestry, there is no security for the brain-power indicated in past success being preserved by inheritance, unless the maintenance of family ability becomes a far more conscious guide in the arrangement of matrimonial alliances than it appears to be in any aristocracy of the present day. Further, little, if any, specialized training has hitherto been provided for such a class beyond the educative experience of men and manners—which may legitimately be considered a trifle narrow—to be gained in a parliamentary career and the earlier stages of executive life. Without proper selection or fitting training the statesmen of the oligarchy may forget inter-racial competition under the bias of class interest, and the intra-racial dominance of a caste become the chief object of a false statecraft.

A secure autocracy hardly affords a like foothold for intra-racial struggle weakening the effective response of a nation to its environment. But its success depends so entirely on a single throw of the dice—the discovery of a man with unique powers of selecting intelligence and organizing ability in his immediate subordinates—that it need hardly be considered as a practical form of government. The discovery of the ideal dictator is a problem which finds not even an approximate solution in elected presidents, still less in hereditary autocrats. It is true that revolutionary processes by which the really strong man comes to the top may occasionally aid a nation at a time of crisis, but they are too expensive in other ways to be aught but a counsel of despair. Historical evolution has left most civilized nations,

after a rough and tumble experience, with a democratic government more or less tempered by oligarchic and autocratic institutions. This may be the best practical solution of the problem in the present stage of national development, but such a system is terribly cumbersome in its processes for ensuring that the keenest brains and the best organizing power of individuals shall be secured as the brains and the organizing power of the nation at large. If the best trained, the most intelligent community is destined to be the surviving type of the present century, then the cry must not only be: Educate your democracy! but also: Select and train your aristocracy for statecraft!

If we may assume, and there is small doubt that we safely may assume, that all qualities in man are inherited, and inherited at such a rate that very few—two to four—generations suffice for selection to produce a class breeding true to itself, then the selection of an aristocracy even by the rough process of ennobling great ability or great wealth (acquired by the owner) is intelligible. But the continuous support by the nation of members of an oligarchic class who have ceased to be of service for aristocratic purposes is futile. In the fourth generation at latest such members should drop out, unless the stock has again proved its capacity by effective national service. The absence of such service will be a sure sign that the original ability was sporadic, that the stock has not bred true, has wasted its intellectual patrimony, or has neglected to train itself for its special functions. The net—meshes not too small, let us remember—must drag *downwards* as well as upwards.

Need for a school of statescraft.

The training of an oligarchic class in statecraft is the first and perhaps hardest task of the modern state. Much, very much no doubt, can be learnt from municipal, parliamentary, and minor executive experience by the man who from youth upwards has resources and leisure. But such a training alone is very narrow; it may be supplemented by leisurely travel, and the somewhat superficial knowledge thus gained of the men of other races, their institutions, aims, and modes of thought. As a preliminary, however, to both travel and political experience, a specialized academic training is really needed. There is a demand for a school of statecraft. The idea is not so absurd as it may at first sight appear; nor, on the other hand, are the chances of its success so great that every university, local college, and night school should rush to establish a lectureship in statecraft! Special schools are best localized at one or at most two centres; they should grow up naturally by the development in a definite direction of an existing educational centre, which to some extent already attracts the class of men to be catered for. We want a specialization and a modernization, in the light of current biological science, of some existing History School. There should be one school at least, where the political institutions of Germany and France are as well known as those of Greece and Rome; where the chief phases of Indian religious development are as closely appreciated as the theological currents of 16th-century Europe; where the 19th-century "discovery of Africa" would be discussed and interpreted in its relation to modern European politics, like Columbus's discovery of America has been dealt with as marking the end of the Middle Ages and the collapse of the mediæval system. There should be one school at least where colonial institutions, ambitions, and developments are studied and appreciated; where national customs, racial prejudices, the foreign press, its powers and limitations, are calmly, and apart from political intrigue, investigated and weighed in the balance; where the students' own nation, its comparative power and influence, its *morale*, and its policy are all dealt with in an atmosphere comparatively free from party strife, and at an age when the mental judgment has not had its roadway worn into ruts by the continual traffic of men and affairs. Sketchy as such a scheme must seem,—its realization could only be a growth,—yet the absence of such a school of statecraft is a partial, if not complete, excuse for ignorance on the part of the leisured and ruling class of more than one modern nation. A class of great ability and organizing power has not only to be gathered together by the drag-net cast over the other classes of the community, but once formed it must have a high tradition in its choice of mates, and a really effective training provided for its members.

The form of government, the right selection of statesmen, is far more important in its bearing upon the true function of science in the state than might at first sight appear. Unless we have the statesman of insight, who recognizes that every function of the state, every phase of national life, has a theory of its own; that there is a right and a wrong way of conducting all state business, whether it be concerned with the wealth, the physique, the intellectual efficiency, or the *morale* of a nation;—we cannot

place knowledge—science in its broadest and truest sense—in its rightful position of consultant alongside the executive. We must have stored knowledge, science theoretical or empirical, at the service of the state for the ordinary routine of every department of national activity; we must also have thinkers and discoverers ready to meet new needs and sudden emergencies; there must be in reserve trained brains and deft organizers both of material resources and of living workers, not only for the constant drain of progressive national development, but, above all, to give the community confidence and reasoned guidance in times of national crisis. The universal rivalry of nations at all points of the globe, the rapidity and ease of modern communications, do not give any nation time to wait for the right man for a particular task to turn up. He must be there fully trained and equipped, so that the executive, the commerce, or the commonality of the nation can seize and exploit him at once. If he is not immediately forthcoming, the fruit will drop into the mouth of the nation that had the luck or the foresight to have its man ready for the occasion. Readiness for pioneer-work is one of the best tests for efficiency in the modern state. The mineral wealth, the climate, the agricultural resources of a new territory are to be reported upon with a view to its incorporation or development: the men to do this effectively must be ready trained and at hand. A troublesome native tribe is to be tutored by the touch of the masterhand: the man who can guide them with experience, with knowledge of their language, of their religion and their customs, cannot be reared—he must be forthcoming on the spot. The trade-rivals of a nation discover a chemical process which threatens some national industry of a second: the chemical or agricultural experts of the latter must be immediately prepared with a process for cheaper manufacture or more intensive production. Another nation invents a smokeless powder or a submarine boat: no neighbouring state can afford to start *de novo* with years of experimental inquiry; its experts—if they have failed, as it is not creditable to have failed, to be first in the field—must be ready with an immediate and effective reply. No nation can nowadays risk being a single step behindhand in its offensive or defensive services, in its methods of production, of trade or of transit, or in the general education of its citizens, —their craftsmanship and their ingenuity,—or, again, in their average physique and reproductive power.

Statesmanship and science.

In the days of old the battle of life was won by the nation with physique, and intelligence enough to guide that physique. To-day victory is to the nation with intelligence, and physique enough to keep that intelligence in healthy activity. In past times the chief store of national power was manual labour: to-day it is the machine that does the work, and not the man; the important things are the brain which organizes and the intelligence which creates and guides the machine. Mineralogical, chemical, engineering knowledge achieve to-day what muscle and brain did a thousand years ago; the chief function of physique is now to maintain the brain in order, and not to act as a machine at the bidding of brain. The old order has changed; from statesman at the helm to craftsman in the shop, modern conditions demand special training, not haphazard selection. Here is the wide function of science in the state. How under existing conditions can science serve the state? How provide guidance in executive, reserves of knowledge, of discovering power, and quick response for emergencies; how train the craftsman, the agriculturalist, the engineer, to be one and all efficient for the international contest? To touch upon these things will be the object of the second section of this paper.

Survival of the most intelligent nation.

II. *Science as Educator.*

The subject of primary education is not one on which much can be profitably said here. Its thorny character arises partly from theological difficulties, and partly from the widespread delusion in the minds of those who have received a primary, or even a more advanced education, that this fact alone constitutes them educational experts. Neither aspect of the case is satisfactory from the crucial standpoint of national efficiency: both involve immense waste in time, energy, and *personnel*. Sooner or later the primary schools must fall absolutely into the hands of the state, and, free from direct local control, be managed by a single council of education and a minister responsible to the national assembly. Every other system is merely tinkering at best; there are not sufficient real educational experts in the country to provide the capacity which is needful on innumerable school boards, to say nothing of parish

Primary education.

committees and district councils. Local vigilance committees may well be organized to see that the national system is effectively carried out locally, but local bodies are not in the intellectual position to draft an efficient system; nor, if they could do so, are they able either to put it into practice economically, or to avoid the friction of local sectarian feeling. If intelligence be the keynote to national fitness for the international struggle, the organization of even the primary stages of the nation's training is as much a national affair as the equipment of the nation's forces for offence and defence: it cannot be left to local management, but must be removed to a higher plane of both criticism and executive organization.

But state control of primary schools is not only essential from this aspect, but also from the importance which must be attached to the nation having a complete and uniform record of the physical condition of its children. Is the stamina of the nation being not only maintained but strengthened? This is a question to which the statesman ought to be able to give at once a satisfactory answer. He ought to be in a position to tell us whether fifteen to twenty years hence we shall be as strong and active a nation as we have been in the past. We are too apt to forget the changes that have taken place not only in the nature of the food supplies, but in the very atmosphere our citizens are breathing. What are the effects of urban or suburban dwellings on increasing numbers of the population; of a frozen meat supply kept for months and possibly years; of foreign ground flour; and of innumerable articles of food and medicine prepared in factories, here or abroad, by processes not wholly scientific, and now sold over the whole country? Possibly but little knowledge of the direct effects of such new factors could be obtained by straightforward inquiry, but a systematic anthropometric record of the schools would tell us whether our children progress or not from generation to generation, and what is the nature of the special precautions, if any, to be taken with regard not only to individuals but to whole localities. Very little extension of the system of observation and measurement would teach the state the effect of particular trades on parentage; the districts where special diseases have to be combated; the localities where special physical or mental aptitudes are to be found; and where it is most desirable to establish secondary and craft schools of a specialized character. In Great Britain we have not only many local races, but many mixtures in diverse proportions of these races. How far are such groups particularly suited to specialized activities? It does not follow that because certain industries have sprung up in the neighbourhood of material resources or of means of transit, that the local population is best fitted to carry on these industries; the sorting and sifting of population, the creation of a local sub-race, suitable to a developing local industry, is by no means so rapid as it ought to be.[1] An effective record, made on a common system, of the physique and intelligence of the children of the nation would immensely assist the quest for suitable types of manual labour or of special intelligence.

Physical record of nation's children.

Or, again, at a time of national stress it may be important to answer a definite question, which could be at once answered from primary school records. We may be struck by some defect in our training, we may attribute want of intelligence in our officers or soldiers to the over-emphasis given in our school system to athletic sports. We may be stirred by ringing phrases like "the flannelled fool at the wicket" and "the muddied oaf at the goal," not to change the bat for the rifle, nor the pad for the pigskin, but to condemn sports in the school as lessening the training required for intellectual development. We may attempt to remedy wrongly an admitted national failure through ignorance as to its true source. Here, again, the schools can aid with a proper record. What are the characteristics with which we find the athletic tendency associated in the schoolboy? Science is now ready with an answer,[2] which would be far more definite and complete if we could draw our statistics from the wide material of a national record. Association between qualities is measured scientifically by the so-called *coefficient of correlation*, which is really a measure of the average relationship between two qualities—it can take every value between zero and unity. When it is zero, we say the qualities have no relation to each other; when it is unity, we consider the relationship perfect or

Relation of athletics to intelligence.

[1] The man who wants horses for a particular type of work, to go at a definite speed, or with a definite load, or on a particular type of metal, will generally be able to find a part of the country where horses suitable for his purpose are bred.

[2] The results given below are based upon measurements and observations of between 5000 to 6000 school children which have been taken for the writer during the last five or six years by the help of school teachers. The inquiry has been aided by a grant from the Royal Society Government Grant Committee.

causal.[1] When it is positive, the two qualities increase together; when it is negative, the one quality increases as the other decreases, and *vice versâ*. Premising so much, let us inquire in what degree our school record shows the athletic character to be increasingly related to admittedly desirable characteristics. We find, if we define the athletic group to consist of boys not only keen on games but proficient at them, that the relationship between the characters is expressed as follows:—

Athletics and good health	·46	Athletics and noise	·35
Athletics and intelligence	·21	Athletics and popularity	·33
Athletics and quick temper	·22	Athletics and self-consciousness	·08

Thus we see that the athletic lad has associated with this character in a very sensible degree: good health, quick temper, and intelligence. His ability in games makes him slightly self-conscious, comparatively noisy, and, as we might expect, popular. He is also rarely *sullen*. Nor is this character substantially the result of his having good health; for we find that the healthy, as distinct from the athletic, have less than half (·09) the association with intelligence, and a scarcely sensible correlation (·03) instead of a fairly high correlation with quick temper. Nor is it a matter of race; for soundness of health is very slightly related to *dark* eye (·07) and *dark* hair (·01) colours, but the *fair* are just sensibly the more athletic (·04). The athletic schoolboy who rejoices in cricket and football is distinctly neither "fool" nor "oaf," but the healthy, intelligent, rather quick-tempered lad who should make a good soldier. Clearly games and aptitude for games ought to be encouraged in the primary school. When and for what they should be laid aside as we approach the real work of life, with its national and industrial demands on the citizen, cannot be profitably studied until we have ample data of the above kind for youth both in the factory and at the university.

Aims of primary education.

To the observer of childhood playing and questioning are its natural functions, and the teacher in the primary school has to develop nascent intelligence on these lines. Playing skilfully means intelligent use of eye and hand,—it is the basis of efficient craftsmanship in the future. Questioning profitably as to the meaning of what is seen, is the basis of discovery by observation—it provides the *principia* of scientific training. To turn the ceaseless movements of the healthy child into the co-operative work of eye, hand, and leg, and its too often meaningless "why" into reasoned inquiry, is the first and most difficult task of the primary-school teacher. Organized games developing into the elements of craftsmanship, inquiry into things observed expanding as time goes on into a conception of the methods of science: these must be the essential features of the state primary schools of the future. Facts are to be secondary, methods of the first importance; the intelligent man knows where and how to find his facts, but he retains no more in his head than he finds economical for everyday practice.[2] His brain is an instrument for work, not a lumber-room. Hence when once the barest essentials of elementary knowledge—the power to read, to write, and to do simple calculations—have been attained,[3] let us adopt largely heuristic methods—collect facts only as aids to intelligent observation and inquiry, and use biology or mechanics, or history or physiography, according to the aptitude of the teacher and the environment of the school, as a means of training intelligence, and not as a store of facts worth remembering for their own sakes. Let the child come out of the primary school able to formulate its questions intelligibly; able to put eye, hand, and leg into co-operative action; able to read, write, and count;—and the first stage in the training of its intelligence to national ends has been attained.

[1] The following series indicates the closeness of correlation in various qualities for purposes of comparison:

High Correlation, 1 to ·75.		*Moderate Correlation*, ·5 to ·25.	
Right and left femurs in man	·96	Out-relief rates and pauperism	·48
Bone length, right and left little fingers in man	·90	Degree of foveation and severity of smallpox attack in vaccinated persons	·40
Stature and femur in man	·80	Coat colours of horse and grandsire	·30
Left middle finger and foot in man	·76	Winter barometric heights in Lisbon and Valentia	·25
Considerable Correlation, ·75 to ·5.		*Low Correlation*, ·25 to ·00.	
Stature and foot length in man	·74	Strength of pull and stature in women	·22
Weight and length of new-born infants	·63	Lengths of lives of mother and adult daughter	·15
Vaccination and recovery in cases of smallpox	·60	Sizes of family for mother and daughter	·11
Statures of father and son	·51	Size of head and ability in man	·06

[2] Not to know the capital of Servia, the tributaries of the Don, or the constituents of the atmosphere, is no sign of defective education. "Facts" change from generation to generation; but skill in manipulating facts is the fundamental sign of a trained intelligence, of a true education, which survives all modifications of its material.

[3] From the standpoint of economy a certain amount of rote teaching must be admitted in the case of the three R's. It is loss of time to apply the heuristic method to English spelling, or to *every* stage in the multiplication table. Nature-study—physical or biological—offers far more profitable material than adding nines to nines up to 108!

But let it realize in the simplest way that this development of intelligence is not for selfish ends. Bring before it from the earliest day the habits of the herd and the hive as illustrations of united work to a common end; let it see that man is lord of all life because he is the most intelligent *gregarious* animal; teach the child by practice and example the effect of combination, the struggle of the social group against its environment, and the progress man has made in effective resistance by co-operation. Let the child very gradually become conscious of the fact that man is fittest not as individual, but as society. In the broadest outline let it see evolution at work on man, and why the social is "right" and the anti-social "wrong." Let it realize that the strong nation is the intelligent nation; and let it early grasp school-teaching as the first stage to good citizenship, and that only the intelligent man can successfully perform the duties which society and the nation demand from each of their members. Here is a broad enough basis for primary schools in teaching the fundamentals of morality, which each sect may supplement in its own special manner. The state, as unsectarian, has first to inculcate the social duties: to emphasise the need of developing the physique, the intelligence, and the spirit of co-operative action as essentials of true patriotism.

Social action as a product of evolution.

From primary we may pass to secondary education, wherein we shall find that far greater changes will be needed in the future than seem at all to be anticipated to-day. For while the subject matter of primary education may well be the same for all classes in the nation, modern requirements urgently demand specialization in secondary education, and to a large extent a differentiation of groups, according to the nature of the work they are to undertake in life. This does not necessarily mean a differentiation of method, nor perhaps of location, but certainly of the subject and of the apparatus used to illustrate method. The great bulk of the population are already at fourteen employed in work or in seeking employment. For this portion, at any rate, there ought to be the elements of a secondary education specialized to their calling in life. Besides the state primary schools, there ought to be craft-schools, possibly separate for the two sexes, thickly strewn over the country. These schools, while largely under state control, ought to be subject to a much greater local influence than the primary schools, partly because theological problems will have been for the most part settled at an earlier stage, partly because the needs of local industries are often best appreciated in their immediate neighbourhood. In these craft-schools we do not want university graduates lecturing upon mechanics or chemistry as they have learnt those subjects in academic text-books or laboratories. We do not want the higher theory of agriculture or engineering such as may be given to the directors and leaders of labour in technical colleges. What is needed is an extension of the object-lesson method of the primary school to the basal forms of labour on which the social fabric ultimately rests. We want to give a system of secondary education to the great bulk of workers, which will make the individual worker an intelligent instrument for his allotted task; we do not require, in the first place, a system which leaves the majority untouched, but raises an artisan here and there to a higher caste. We need a system of education for the bulk of men, who follow, entirely independent of the system requisite for the minority, who organize and lead.

Secondary education.

Secondary craft-schools.

The craft-school, in the few years in which it can handle its material, must achieve two things, both tending to strengthen the national fitness for survival, namely, it must lay the basis (1) of good craftsmanship and (2) of good citizenship. Under the first heading no form of labour is to be considered beneath educational treatment. Taking first the rural craft-schools, no agricultural or horticultural process is or ought to be without a basis of scientific theory; hedging and ditching, ploughing, hay-making, harvesting, care and handling of horses, cattle, sheep, and pigs, all that falls to the lot of farm-labourer, shepherd, hind, and groom, can be treated intelligently. They can all be dealt with by the object-lesson method,—observation, and deduction from what is observed. On the girls' side, milk, butter, cheese, poultry, household work of every description, can be used in the same way as material for showing how to do things intelligently. Education is in no case to leave the feeling that it is finer to follow one trade than another, but is to develop the consciousness that it is a disgrace to follow any craft without intelligent appreciation of the why of its processes. The victory is to the intelligent nation; that nation is intelligent in which each member performs his allotted task with appreciation of how and why it is done.

Rural craft-schools.

The pure scientist still occasionally speaks with contempt of the technical side of education. If technical education be merely a knowledge of the facts and formulæ used in special industries, he is entirely in the right; if, on the other hand, technical education means the illustration of scientific method on the material and appliances used in a particular trade or craft, he is hopelessly wrong. It is as possible to give scientific instruction on the apparatus of a craft as upon the delicate toys of the academic physical laboratory. The horse and the pig, the growing crop and the vegetable garden, are as replete with lessons in scientific method as zoological or botanical laboratories with their microtomes and microscopes. The science of elasticity may be as effectively studied with the 60-ton testing machine on the materials of construction as with pound-weights on the rods and wires of the physical laboratory; thermodynamics is, perhaps, as instructive a science when illustrated on the steam- or gas-engine as when a diagrammatic air-engine appears on the lecture-room table; and there is a reality about the inertia of machinery in motion which illustrates momentum and energy in a somewhat more convincing way than the falling weights and the rolling balls of the academic mechanical laboratory.

Pure and technical science.

We have diverged here far beyond the humble limits of our craft-school, but it seemed necessary to insist once and for all on the great principle: that technical instruction can be scientific in the best and highest sense; scientific method can be inculcated and illustrated on the material and apparatus of any special craft or employment as well as with the costly buildings and delicate apparatus now demanded for academic purposes. If it be said that apprenticeship is the true craft-school, the argument is valid, so far as many facts and empirical rules have still to be learnt in the shop, on the farm, or at the bench. But our secondary craft-school is to be preliminary to work in field and factory, it is to inculcate what the master or fellow-workman has not the time, nor usually the power, to do, namely, to emphasize the importance of intelligently following out each craft-process. The secondary craft-school must inspire its pupils with a desire to know the reason for the rote which apprenticeship is sure to thrust upon them. The secondary craft-school is not to be too specialized—at least not in rural districts; its pupils must spend much of their time on the farm, in the local factory, in the carpenter's shop, and at the smithy. They should not be required to learn the elements of mechanics out of examination text-books; nor be pushed on to the extraction of cube roots, as if that were the crowning feat of mathematical instruction. Let the pupils measure a plot of garden ground intelligently, the capacity of a barn with reference to the size of crop it will hold, or the cubic feet of air in a stable or stall with reference to the air-space necessary for healthiness of cattle; the approximate amount of half-inch planking to be obtained from an unfelled tree (to be tested after it has passed through the local sawmill) —these and many other exercises will occur to the intelligent teacher. Let his or her work be supplemented, too, by occasional lessons from the highly-trained artisan, the carpenter or millwright, the head-gardener, the shepherd or the dairymaid, or from the workers in any other crafts which are locally available and offer craft-workers of experience. The intelligent craftsmen may be scarce at present, but as the secondary craft-schools pass more and more of their pupils into local activities, and possibly keep touch with them through the higher craft-schools, through continuation and night-schools, the material to draw upon for occasional lessons, and possibly for permanent teachers, will become more extensive and better.

Apprenticeship and craft-school.

In the town districts the secondary craft-schools ought to be more specialized; some of their work is already being done by so-called technical schools and polytechnics. But these places and their courses are largely chaotic at present. They have not settled whether it is their function to give secondary craft-education to boys and girls, to give higher craft-education to the non-commissioned officers of industry, to train the commissioned officers themselves—the proper work of the higher technical colleges,—or to provide cheaply a one-sided and, in nine cases out of ten, inferior academic education for young men and women who believe their success and standing in life will be assured if they are hall-marked with a university degree. It cannot be too emphatically asserted that absolute differentiation in function is essential for success in technical education, especially in urban districts. There must be secondary craft-schools which will supplement primary education, by illustration of scientific method on the elementary processes of most forms of labour. Boys and girls will leave these schools not later than thirteen to fifteen, roughly pre-

Urban craft-schools: present chaos.

pared to follow intelligently the lower grades of industry. There must be higher craft-schools, with much more specialized instruction, for the non-commissioned officers of industry. There must be technical colleges for the leaders of industry, and universities or university-colleges for pure science, literature, and other types of brain-work; these again must be supplemented by professional schools for medicine, law, actuarial training, &c. &c. There must be for the most capable pupils a possible passage from secondary to higher craft-school, and from the latter to the technical college, or in special cases, where pure scientific capacity is noted, a transition to the university. But the nation which fondly imagines that one class of teacher and one building will serve for all these diverse purposes, and calls it a polytechnic or a university-college, is only excelled in folly by the nation which clubs a dozen such hybrid institutions together and supposes that they form a working university! Such a nation has not learnt the *principia* of educational theory, and the sooner it learns from the nations that have, the better for its welfare if that depends upon industrial efficiency. The secondary craft-school, the higher craft-school, the technical college, and the university serve quite diverse functions, educate for different careers and occupations in life; if economy or convenience bring any two under one roof, then there should be a differentiation of teachers; if even this be not possible, there should be at the very least a differentiation of material and of plan of instruction.[1] Otherwise, there is the greatest danger that instead of intelligent workers in the ranks, the secondary schools turn out a superfluity of incompetent non-commissioned officers; the polytechnics provide non-commissioned officers who know only the duties of the subaltern, and the colleges subalterns with the making of pure scientists, but not of technical leaders.

Scope of secondary craft-schools.

In urban districts, from the higher grade or continuation board-schools, and from one side of the polytechnic teaching, must arise the perfectly distinct secondary craft-school, educating boys and girls to be intelligent workers in the ranks of specialized industry. It must go no further than the attempt to show that all forms of manual labour can be performed intelligently: its aim is the real, or at any rate the idealized, craftsman of the Middle Ages, the man who loved his work, because he realized the why of it, and its relation to a greater whole. There is no doubt that the highly-differentiated character of some branches of modern factory labour—by no means all—tells against intelligent craftsmanship. For this reason the secondary craft-school must not be too specialized, even in urban districts. The demand of the state for intelligent citizens is equally important with its demand for intelligent craftsmen. Hence it should be a *sine quâ non* of every craft-school, whether secondary or higher, that each pupil should study one branch of pure science, or one literature, or one historical period, apart from his technical studies, as a field for rational enjoyment in adult life. Let it be done as recreation, not as task; but let its effectiveness be a condition of any state or municipal support to a craft-school. It has been in the past such a noteworthy characteristic of the British race to produce amateurs, following professions, trades, or even handicrafts, who have done first-class historical or scientific work, that we may hope that the absolute need for differentiation in education and the specialization of the smallest branches of knowledge will not finally check this production. The encouragement in the craft-schools of a special recreative study might be of most material importance in this direction. If care be taken that not facts and formulæ, but the scientific method and spirit, are illustrated on the subject and appliances peculiar to the craft, very little time or energy will be expended in merely applying the notions of scientific observation and reasoning thus obtained to the recreative study. In the higher craft-schools and technical colleges, lecturers of the university-extension type would find a most useful field for their energy and enthusiasm in teaching recreative branches of literature or science, and above all in showing the pleasures of a library, apart from its value as a store for facts and formulæ, its most important function on the technical side. In the secondary craft-schools, also, the "citizenship" teaching should certainly be carried a stage further: both boys and girls should learn a little, if only a little be possible, of the reason for and history of the institutions—national, municipal, and social—which, as citizens, they will have to work under and develop.

[1] To give a man control of a higher craft-school because he has taken a brilliant university degree in pure science is a common illustration of the present chaos in technical education in England. It is hardly excelled by the offers of *teaching* posts which the high wrangler receives the day after the appearance of the class lists.

Lastly, in no secondary craft-school ought the need for athletic exercises to be disregarded. The anthropometric record of the primary schools should be continued, that it may serve as a control for comparative physical progress. But a certain portion of the time devoted to athletic exercises should now be applied to developing qualities which may hereafter be of service for national offence or defence. The rural lads should be taught the elements of drill, rough road-making, the ready use of pick and shovel, and the fun of scouting games; where possible, rifle practice should be introduced, and swimming and even riding be taught. For the lads of urban secondary schools some of these matters are difficult enough; but the plan of holiday camps in the summer may be widely extended,[1] rough map-making and scouting can often be practised on suburban heaths, and opportunities for drill and swimming, rough carpenter's, saddler's, or shoemaker's work can nearly always be found. In all these cases let it be recognized by the lads themselves that these things are not craft-training, but are taught to fit them for duties which a strong nation demands of all its citizens in one form or another. In the case of the girls the horizon must appear somewhat narrower, and it is, perhaps, only their teachers and elders who can realize the national importance of those forms of physical training which may aid them to be the healthy mothers of a strong race. Still it is highly important that they should realize that they belong to a larger whole: that they have a function in the state as well as a relation to individuals. Bandaging, first-aid, the elements of nursing, the care of infants—and of the aged—may all be taught as extensions of household economy, and the social value of such work inculcated. But they are not essentially outdoor physical exercises, and the latter, whatever be their real import, must bear for the girls the aspect of mere games, not of sports obviously directed to national ends.

Athletics in secondary schools.

To sum up, then, our conclusions as to the functions of the secondary craft-school: it is intended for the rank-and-file workers in all the industries and crafts of the country. It should provide: (i.) Training for the intelligence, by illustrating scientific method upon the material and appliances of every craft. As the elements only of the craft will be considered, many crafts will be combined in one school, but greater specialization may be possible in urban than in rural districts. (ii.) Recreative Studies, (iii.) Citizenship Course, and (iv.) Athletic Exercises. The bulk of the instruction will fall to the lot of the permanent teachers under (i.); subjects (ii.) and (iii.) may well be undertaken by a specially trained class of peripatetic teachers; while (iv.) might largely be aided by volunteer workers, whose labours should be guided and systematized by district advisers, who would travel from school to school, suggesting and organizing the service with a keen eye for local possibilities.

General functions of secondary craft-schools.

If from the secondary education of the rank-and-file workers we turn to that of the leaders, we have at once the differentiation into the two classes of non-commissioned officers or foremen, and of the commissioned officers, or the leaders of industry, the brain-workers, thinkers, and educators of the nation. Probably the first class will be largely drawn from those who have shown marked capacity in the secondary craft-schools; these should be passed on to the higher craft-schools, the work of which will be dealt with later. When we consider, however, the provision hitherto made for the nation's intellectual leaders in the matter of secondary education, one is surprised, not that the nation has gone relatively backward, but that it has survived at all in the keen competition of modern times. A nation needs organizers, leaders, thinkers, not only in commerce, but in manufactures, the technical arts, transit, colonization and exploitation, pure science, professional and literary pursuits. Up to the immediate present hardly any secondary education at all has been provided suitable in the least degree for a college training in any one of these matters except the last. Our commercial and technical leaders have rarely had any scientific training at all; they have grown up without it, and held their own owing to the political and economic conditions of their country relative to its rivals. Such will be an absolute impossibility in the future, now that the equal or superior sources of power of our rivals are being worked, and the plant is created and the labour trained which is requisite for production. Granted that resources and machinery are alike,—they are now far from being in our favour,—it is only

Secondary education of middle classes.

[1] The camp-holiday system, which has flourished a good deal under voluntary effort during the last few years, ought not only to be developed and widely extended, but supplemented, if possible, by short summer cruises on training brigs, where the lads would receive a different kind of drill and learn a little, if the veriest little, of what the sea means.

the most highly trained intelligence which can turn the balance to our side, or even equalize it. Yet what has happened? The movement for technical education has led to the establishment of a number of technical colleges, where a more or less efficient technical higher education can be obtained, but it has not provided the essential stepping-stones to this education: namely, secondary schools up and down the country specializing in commercial, technical, and scientific instruction. Occasionally the modern side of a large school may be found doing good work, but its existence at all is an exception, and it is an exception among exceptions if it gives a training useful for technical purposes. A Cambridge wrangler, who teaches to an occasional student an arid text-book on the calculus, with a view of his getting a scholarship; academic laboratory work of a physical or biological character, boiled down and sterilized to suit the youthful digestion; formulæ from algebra, facts from mechanics: all these exist. But in nine cases out of ten no direct and conscious training in scientific method, no teaching to observe, classify, and reason on facts collected by the lads themselves.[1] No specialization by *trained* teachers for commercial, technical, and scientific pursuits is in the majority of cases thought of; and since it would largely have to be provided by men not educated in the ruts of the older academic methods, there is small doubt that both teachers and taught would be looked down upon as of a lower caste. Desirable as it is to associate lads who are about to follow very diverse callings in life, there is small hope of efficient secondary education, specialized for commercial, technical, and scientific pursuits, being provided in the majority of our great public schools, with their traditions and systems centuries old. These modern schools will have to be founded *de novo*, or developed out of the large day-schools of urban districts, or the decadent rural grammar schools, which up and down the country may be found, atrophied under a system which was, perhaps, a vigorous reform in the second half of the 16th century, but supplies no urgent national need of to-day. Let there be no doubt, however, about the nature even of the commercial education we are considering; it is not intended to turn out commercial travellers and clerks, who fall into the class we have termed non-commissioned officers. For these the secondary and higher craft schools should provide. The scheme is intended for the leaders of industry, for the men who will be manufacturers, merchants, shippers, engineers, the organizers and thinkers. These are the men who will pass on to the technical colleges and the commercial universities of the future. As the German technical universities[2] draw their students from the *Realschulen* and not the *Gymnasien*, so our technical colleges need an effective technical and scientific secondary education antecedent to their work. We have the German experience to draw from and to learn from, and we ought to be able to create schools which will turn out a lad with all the healthy traditions of English public-school life, but who has replaced its classical education by an effective training in the methods, not the results, of scientific inquiry.

Need for modern schools.

To the general outline of these schools much that we have said of the secondary craft-schools will apply. The teaching will have to a considerable extent to be specialized—commercial, technical, and purely scientific departments being provided with different teachers and methods. In each case the primary object will not be to give the lad information useful to him in his future calling, but to develop his intelligence by the application of scientific method to the material and processes with which he will later be concerned.[3] Again, to prevent narrowness we must have the recreative study; and to strengthen social stability, the citizenship lessons. Athletic exercises, culminating in some knowledge useful for purposes of national offence or defence, must not of course be omitted. But as the secondary education of the classes we are considering will last at least two or three years longer, the extent of these secondary studies can be considerably increased. Thus the ground-

Functions of modern secondary schools.

[1] Every teacher in a technical college knows well the average public-school lad: personally delightful, athletic, popular, he cannot draw, his geometry is a rapidly disappearing acquaintance with Euclid I. to III., his algebra a formula for quadratics, and his arithmetical accuracy sadly inferior to that of a shilling slide-rule. His secondary education has to be undertaken over again, and even then he will probably end in the South African Constabulary.

[2] The German *Polytechnikum, technische Hochschule*, is not for the moment to be confused with our polytechnic, which ought to be a higher craft-school and is a hotch-potch of a dozen stages of education. It corresponds more to our technical college, but is ten times as complete. It usually represents the complete technical university, and by government decree its teachers and students are placed on an academic footing.

[3] One man may learn how to use his reasoning powers from a teacher who adopts Greek grammar as his medium, another from a teacher whose material is provided by the hedgerow, and the powers gained in either way may be turned from one to another subject; but there are obvious advantages in selecting for the object-lesson material at least akin to what the reason is ultimately to deal with.

work of a true culture—the superstructure of which must always be self-culture—can be laid in the technical college or science school. An important addition, however, should be made to the teaching of such modern secondary schools, not as part of the recreative but as part of the bread studies,—a reading knowledge of one, and a speaking knowledge of a second language should be insisted upon. The doorway into another race's scientific laboratory, its methods of work and of expression, is as important an opening for the mind as the doorway provided by a knowledge of its language into its institutions, literature, and folk-feelings. To grasp how a great investigator works needs presence at his lectures or in his laboratory, or at least the study of his papers,—it is an education which can never be obtained from text-books. In any specialized branch of science there are rarely at any given epoch more than two or three master-minds, and these are diverse in country and in tongue. To follow these personally or in the written word is an impossibility without linguistic knowledge, and science-abstracts and text-books are a deadening and nigh worthless substitute for direct contact with a master-mind. We shall insist later on the national importance of the *Wanderjahre*, but to profit by such years the young apprentice must have received in his secondary school the groundwork of at least one language, and maintained and developed that knowledge at college. The pure scientist or the professional engineer who cannot directly study the work of contemporary foreign investigators is most heavily handicapped, and in many cases a tenth of the time and energy he will spend in finding out how to do things already done would have given him a reading knowledge of foreign literature. The speaking knowledge of a language serves a different purpose: it is essential to the pioneer in commerce, exploitation, and transit.[1] Started in the secondary school, it may be completed in the *Wanderjahre*; it is a practical instrument of a man's calling—like the multiplication table, he requires to be sure of it, but he will not, like the philologist, make it a means, in the first place, of intellectual training.

It would be out of place here to give even outline curricula for the secondary modern schools we have in view. If the curriculum of the secondary classical school has only been crystallized out in the course of many generations, no new scheme for science schools will in itself be wholly satisfactory, or work without initial difficulties and friction. In the first place, the teachers, to do the work effectively, have largely to be made. In the next place, parents have to be convinced that the secondary modern school is not going to provide knowledge useful in professional life. It is going, like the classical school, to develop the intellectual powers, but it will take as its material not the dead languages, but the living sciences which bear most closely on commercial or professional work. There will be, undoubtedly, specialization and differentiation. The biologist and the physicist receive their intellectual education in observing and reasoning on a certain class of facts—they need mathematics as an instrument of investigation. The mathematician who insists that they shall have it as an intellectual education only is going beyond his legitimate sphere. In the same way, the engineer receives his intellectual training in a field very unfamiliar to most physicists and mathematicians, and the teachers of mathematics and physics who insist upon these subjects being taught to him as intellectual exercises from the pure-science standpoint are the bane of technical education. Secondary schools, like the higher craft-schools, will do little to improve technical instruction if this point be not kept in view: the teachers of pure science required for the technical side must be men trained in a technical college, and having touch with the needs of practical life. Such men ought to be distinct from the teachers of pure science on the science side, who ought to be men who have been through research schools and laboratories, and whose first aim will be pure science as an education, not as an instrument.

Nature of teachers.

Lastly, if we consider the secondary education given in the public and large day-schools as they at present exist, in many ways well fitted, perhaps, for professional and literary careers, we can only hope that the opening up of large secondary modern schools, turning out pupils of equal intelligence and better fitted for modern commercial, mercantile, and technical pursuits, will serve as a stimulus to quicken and, above all, humanize their activities. They will certainly decrease in

Secondary classical schools.

[1] While French and German for the English-speaking races are the more valuable languages for the storehouses of method and knowledge they throw open, Spanish and Dutch are perhaps at present most useful for pioneering. But it is nationally important to have a great range of choice in the spoken languages among workers in both the commercial and technical fields.

number, but this does not necessarily mean in efficiency; and where the endowment allows of a complete duplication of staff and educational apparatus, the running of modern and classical schools side by side would have all the advantage which the admixture of men of different callings, modes of thought, and social standpoint provides in after-life. Before the renascence, teachers of the old monastic learning would have denied that it was possible to improve their methods, or to change with advantage the subjects taught. Yet within fifty years the Humanists reconstructed the school-education of all Europe. They achieved it by raising an enthusiasm in youth, which demanded that instruction should be for both teachers and taught a vitalizing process and not a drudgery. A small minority of teachers with the new ideas, and a wide-spread rebellion of the taught, swept the old system and its professors swiftly and forever away. The abuses of to-day do not perhaps justify, nor the tutelage under which young people now stand[1] permit, of quite such a drastic reformation. Yet the pressure of competing modern schools ought assuredly to modernize classical and philological studies. We want to train the intelligence of each future citizen to observe and reason about facts, and this power can never be fully developed when the material dealt with is isolated from all relationship with present experience or living modes of thought. The scholar has to realize that he is merely a unit in a living nation, which is one among many nations, each with a history of its own. The study of a special literature or language may be very harmful if it is not seen in perspective. It leads to the spirit which supposes that philosophy was summed up in Aristotle, that style culminated in Cicero, that there is only one great religious work, and that Euclid provided once and for all what is needful for geometrical instruction. Comparative history, folk-lore, and custom,—the discrimination of what is peculiar and what is universal in the institutions of the special people studied,—are all needed if the scholar is to be saved from narrowness. The *Odyssey* is not only a great epic, it is intensely exciting as an object-lesson in the early stages of civilization, in the growth of mankind from boyhood to adolescence. The institutions of early Rome are unintelligible without comparison with Teutonic, Slavonic, and even African folk-customs and religious practices. Style and taste are never to be despised; but what we want the cultured lad of to-day to understand is what man now is and how he has come to be what he is. The over-emphasis of one period, one literature, one art or language, may be dangerous if it tends to obscure the fundamental principle that man is the product of an evolution, under vital forces of which science knows something and is daily learning more. No nation was ever without rivals, moulding and modifying its development; no literature without a growth; no art or craft without an historic evolution; no human product, judged from either the artistic or intellectual standpoint, final. The schoolmaster who forgets these things is not truly preparing lads to be thinkers and leaders for the nation; the academic teacher who does not make them the thread of his exegesis will aid little towards the much-needed humanization of the older forms of study. Neither religious thought nor educational theories can stand aloof from the growth of scientific knowledge. One and all react upon each other. We cannot stand now where Virchow did in 1877: the pressure of foreign commercial competition has been a conclusive object-lesson in the survival of the fitter. We must base national education on the need for national reaction against a changing environment; we must consciously prepare for the struggle, and by an intelligent study of human evolution arouse the patriotism and race pride of the young to assist directly in developing their intelligence for national ends.

Higher craft-schools.

Before we pass to the specialized college education, a word ought to be said of the higher craft-schools, which should supplement secondary craft-schools in the preparation of the non-commissioned officers of industry. Hitherto these schools have either been wholly wanting or supplied by private enterprise bent on personal profit. The keynote to such a school should be intelligent instruction in a craft suitable to lads of fourteen to seventeen who hope to be foremen workers. It should lay more stress on technical knowledge than the secondary craft-school, where the development of the intelligence is the first requisite; but it must, like all true education, appeal to the reason as a guide. It must also be far more specialized. We need higher craft-schools in plumbing,

[1] In mediæval times the lad of fourteen to seventeen might wander across Europe seeking for the school reputed for its methods, or attracted by the vigorous teacher. The *Wanderjahre* for the schoolboy are, perhaps, wisely abolished; they will, let us hope, be reinstituted for the undergraduate.

farriery, cabinet-making, textile industries, metal-plate work, and a dozen other different things. As usual, we began with the wrong end—establishing examinations in these subjects, rather than model schools. Nor have the so-called polytechnics and technical schools of the county councils—good although the work has been in *some* cases—wholly made up the leeway. The technical school or polytechnic, instead of throwing itself body and soul into a special branch of craft or industry, has aped the university. It prided itself on getting a few students labelled B.Sc., or on producing a small piece of pure-science research having no bearing whatever on the national industries. It aimed at turning out second-rate engineers, rather than first-rate machinists. The result has not been, and cannot be, that great increase of craft efficiency which we might expect from the amount of money expended on technical education. The polytechnic may become a centre for a mild form of general instruction and amusement, or it may become a specialized higher craft-school. It cannot effectively fulfil both functions. In the first case it will probably fail, as the mechanics' institutes of last century have failed; in the second case it will become not only of local but of national importance. Let one technical school devote itself to smith's work, another to the printing and lithographic arts, a third to the glass industries, a fourth to bookbinding, and so on,[1] not duplicating their work and teaching many things superficially.

Need for local specialization.

Some large towns may maintain a considerable variety of specialized schools, but it is the student who ought to wander; repetition of staff and teaching material at a dozen centres means waste and inefficiency. If Birmingham founds a higher craft-school for electroplating work, Wolverhampton may reply with a metal-plate-work school; if the Whitechapel higher craft-school specializes in cabinet-making, Clerkenwell may find a wide enough sphere in the glass trades. The bane of technical, indeed of all education of an advanced kind in England, is the unreasonable overlapping of institutions, teachers, spheres, and methods. The higher craft-school has nothing to do with academic training, therefore we appoint academic scientists to teach in it, and place them on university faculties; the technical college has a separate but coequal function with the university, therefore we mix them up, thinking one method of teaching and one teacher will serve for both. We send peripatetic teachers out to fulfil the all-important function of raising the general culture of the people: we fancy it academic extension, and demand that it shall lead to a university degree. Nay, a degree having come to be looked upon as a mark of caste or gentility, the branding-iron is, in the true democratic state, to be brought to every man's chamber. At the basis of every science are real philosophical and intellectual difficulties; in its structure, endless lessons in observation and in method; at its summit, the prospect into still untrodden lands. Not one of these things can be indicated by an examination schedule; they are scarcely touched by any text-book which follows such a schedule. They are appreciated only when the student comes into personal contact with the creator of knowledge, and sees how he observes and reasons. Here is the field of true academic work; no branding-iron brought to a man's chamber can testify that he has been in contact with this vivifying atmosphere. Nor can we bring science and learning in their highest expression to each student's door. He must go out on his *Wanderjahre* in pursuit of the master-teacher, or of the school which has specialized in his chosen study. What is true of the university is equally true of the higher craft-school: the student must seek the specialized teacher and the specialized school, and not trust a local polytechnic to be an effective educational *omnium gatherum.*

Higher commercial schools.

Besides schools for the more mechanical crafts, we need higher schools for the lower ranks of head-workers, for the lower branches of civil and municipal employ, for shorthand and clerks' work, for postal, telegraph, and railway service. Some of these employments—where students will pay to be got through an examination—are at present provided for by private enterprise. But such schools want organizing as a comprehensive system, and should not be based on the question of immediate profits derivable from some small section of the work. To such schools the government, the municipality, companies, and private employers would very soon learn to turn for a specially-trained class of employee, and we might hope that in the first instance they would ultimately replace the Chinese system of selecting by examination.

[1] To some extent this has been begun with the textile schools in the North of England, and the photographic and optical instrument schools in London, but these are the merest beginnings only.

We now turn to the highest forms of education, which, whatever we may hope for in a distant future, can at present only be organized for the brain-workers of the community—for its thinkers and leaders.

Higher education. Here we find much the same educational chaos as we have had to note lower down in the scale. With as great, if not greater, need for it, there is even less organization and specialization. As a first classification, we may consider our subject under four headings: (i.) the university proper; (ii.) the technical college; (iii.) professional schools; (iv.) the commercial university. How far these four phases of advanced education can be advantageously united into a single university system is not easily determined. In Great Britain the advantages of union are: first, that as education becomes more specialized, the larger funds accumulated during many generations for the university proper may be shared by the younger branches of study;[1] secondly, it is of immense gain that both students and teachers of specialized studies should mingle together, and share traditions common to all. This is what must take place in later life, and the joint university provides, from student to professor, an excellent training in toleration,—a characteristic as important in science as in theology. On the other hand, the union of the four schools in one locality and institution is likely to disguise the absolute need for entirely independent staffs, and for completely specialized methods of study. The doctor and the engineer require mechanics and chemistry, but to teach medical and engineering students in the pure-science laboratories of these subjects is an evil only sanctioned by absolute want of funds, and solely due to the haphazard growth of British systems of education. Look at the specialized staff of one of the great German polytechnics,—a dozen professors and double as many more lecturers and assistants,—and then compare such staff with the roll presented by any university or technical college in Great Britain! Nine out of ten of these colleges think it sufficient to provide a so-called professor of engineering, and send their students to pick up what mathematics, what physics, what chemistry they can under teachers who have had no special technical training, who have never studied the special needs of engineering students, nor published a single memoir dealing with technical problems. The result of such a system is manifest: we have no research in the sciences preliminary to engineering; not even first-class text-books, for the preliminary science teachers in the engineering schools are, if not overdone with teaching, workers in pure science. It is very little better in the matter of engineering research pure and simple. The professors are not able to specialize, partly because they have to teach too many subjects, owing to want of colleagues and of the fitting secondary and preliminary scientific training in their students, and partly because they have not been themselves educated in an atmosphere of research. We do not think there is exaggeration in this statement of the case; we have not overlooked certain text-books on the strength of materials, machine-design, or the steam-engine. Rather these illustrate our text: they show that want of knowledge of the modern theory of elasticity, of kinematics, or even of foreign contemporary work, which indicates how pressing the need of an effective research training may be in even the highest places under our present system.

We are undoubtedly far better off now than we were a generation ago; the technical schools up and down the country are doing good work, but they are not in any case comparable with a German polytechnic, nor with the technical university which we must hope to see ultimately established here.

Technical colleges. The University of London, for example, comprises three or four engineering schools, each duplicating much preliminary work; combine their staffs, specialize their individual teachers, give them leisure and laboratories suitable for research, and there would be only the foundations of one real technical university. Yet no other university or technical college in the country could produce as much. We have started again on the wrong system—multiplication of little centres, doing their individual best no doubt, but not what is best for the nation. Three or four technical universities would suffice for the whole nation, but we have established fifteen or twenty technical colleges, on the theory that knowledge, like milk, must be delivered at each man's door. The result is that all the schools are, broadly speaking, doing the same elementary work, and there is no specialization. No one school devotes itself entirely to civil engineering, naval engineering, hydraulics, municipal work, gas, electric lighting, or haulage, &c. &c. The elements of many

[1] Thus it is satisfactory to hear of College fellowships at Cambridge being given to engineering students for technical dissertations.

things are touched on, but the higher teaching and the atmosphere of research are largely absent. What then is needed?

The technical university.

The development of three or four only of the technical colleges of the country into technical universities, with specialized departments of mechanical, civil, electrical, &c. engineering and of chemical industry. The remaining schools should disappear or be converted into higher craft-schools. Use their staff or buildings, where possible, for special departments of the university, but recognize once and for all that under the stress of modern competition these are matters of national importance; and that to bring our technical intelligence up to the level of that of our neighbours, we do not want local engineering professors, or local colleges, but national technical universities, each with ten or more complete laboratories, a score of special technical professors, and with equipment and funds comparable only with those of the whole of the pure-science faculty of a first-class modern university. Such universities would train not only the nation's industrial leaders, but the teachers for the secondary and higher craft-schools; and by bringing both classes into touch with actual knowledge-making, indicate on the one hand how the problems of practical life, on the other the problems of craft education, may be met and solved.

The university and its future.

If we pass from the technical university to the university proper, by which we are to understand the corporation of teachers which deals with training in pure science or scholarship, without regard to the needs of special industries or professions, its work in the future seems likely to become more specialized. There will always be minds for which the best intellectual training, independent of future calling, will be an end in itself. Senior Wranglers may make good judges; senior classics, excellent doctors; and double-firsts, capable statesmen. But in the case of modern nations specialization of the individual appears to be a progressive feature, and as soon as it becomes a recognized principle that the intelligence can be trained and developed by observation, and reasoning on observation, applied to technical or professional subjects, much of the monopoly value of pure academic studies will disappear. The study of yeasts may be as good an intellectual training as that of the gases of the atmosphere; bacteria are as mentally exciting as snails; the vibrations of a bridge lead to more aspects of physical science than those of the tuning-fork, and examples may be multiplied to show that technical or professional education is not one-sided or intellectually inadequate. It seems likely, therefore, that academic studies, whether purely scientific, literary, linguistic, historical, or philosophical, will tend to be recognized more and more as a training for specialized careers, namely, for statesmen, scientists, historians, literary men, educators, and makers of all forms of knowledge,—in short, for the intellectual leaders of the nation. With this recognition, academic studies will become more intense and definite in character. Above all, the research training will more and more supplant the examination training. In actual life it is the problem which comes to us; stores of facts are accessible—we want the training which enables us to apply these facts and solve the problem.

Reformation of academic studies.

The recognition of this fundamental fact is the reformation which must take place in academic studies. Examination is by no means the best process for testing the power to observe, classify, and reason on observation. The known itself may be made the subject of a formally new inquiry, and a monograph may be written showing data, classification, and deduction;—the method is equally applicable in physics, biology, or history. It forms the basis on which the capable instructor can point out the sources of information, the proper method of arranging it, the logical results which flow from it. Scientific method, the true spirit of inquiry, is better learnt by criticism and suggestion applied to two or three such monographs by the master-investigator, than by months of labour devoted to learning the known for examination purposes. We cannot too often repeat that for the purposes of education what we need is a training in method, and not, in the first place, a mere knowledge of facts, nor even of the laws under which these facts may be classified. It is so easy to provide facts and formulæ, so difficult to give insight into method, that text-books, degree schedules, and examination papers invariably turn to the former; and the latter, to be learnt only from direct touch with the investigator or from the classical memoir of the master, is thrust ruthlessly aside. Treat the known as unknown, to be rediscovered, or bring the student rapidly to the real unknown on the confines of the

discovered, then true training in method becomes a possibility. Every nation is daily being confronted with new problems; they may be material, or they may be social, or they may be intellectual. Admit progressive evolution, and this statement is an obvious truth. The nation's brain-workers, whether their rôle be great or small, have to be prepared to meet and answer these new problems. Training for examination is but feeble equipment, certificate of examination success very one-sided evidence of competence for this essential function in a nation's thinkers. Nor is the reader to suppose these remarks apply only to the training of master-investigators in any branch of human knowledge; the academic training is that upon which the great majority of secondary educators depends, and their present failure to apply, or rightly apply, heuristic methods is largely due to the examination system not having brought them into close touch with the methods of research. Nay, our professional and commercial classes suffer in international competition from much the same want—definite training in observing and reasoning upon facts. The university of the future will bring its undergraduates, not into touch with an army of tutors and "coaches," nor with their impedimenta of examination schedules and text-books, but directly into the field, the library, the laboratory, where the material of knowledge is accumulated and classified, and into personal touch with the men who make it.

The professional college.

The problem of the professional college or school of academic rank and its relation to the university is one of considerable complexity, and can hardly be dealt with at length here. Specialization is the most emphatic note of modern national development; it has to be met, not by protest, but by providing for training in *method*, even when a special or somewhat narrow class of facts is dealt with. The establishment of technical colleges for engineering, metallurgy, chemical industries, navigation, agriculture, and forestry [1] indicates to some extent the direction in which the older academic faculties of law, theology, and medicine must develop. It is fundamental that the preliminary linguistic or scientific studies should be, as in the case of the technical colleges, in the hands of a special staff, distinct from that of the pure academic studies.[2]

The law school.

It is difficult to understand why great law schools do not thrive in this country. No other nation can present such living object-lessons in comparative law: it rules in different parts of the world under nearly every present or past legal system, and by innumerable forms of folk-custom, which exhibit legal institutions in almost each stage of progressive evolution. Yet comparative and historical knowledge is very largely lacking in our practical lawyers; but few of them are acquainted with the French, Dutch, or German codes, or have gained insight by a study of the development of the early Teutonic and mediæval systems. The result is a want of imagination in our own domestic legislation, and too little sympathy in dealing with the legal institutions of subject or assimilated races. The law schools have thus partially failed to create the class of men needed by the nation for its legal work in all corners of the globe. The broad idea of satisfying a national want has not been a primary consideration, and to this extent they urgently require that humanization which is demanded in the history school, if it is to become a school of statecraft.

The medical school.

Perhaps in the case of the professional schools the most complete chaos in educational matters is to be found on the medical side. In the first place, it cannot be doubted that the hospital system itself must soon suffer a profound modification. It is impossible that the present system of support by fluctuating charity can permanently continue. Alongside the public charities have arisen infirmaries, fever hospitals, and asylums supported by public funds, and in

[1] In the last three cases the colleges should be for the scientific experts, not for mariners, farmers, and foresters, who require, in the first place, higher craft-colleges. What might be achieved in the science of navigation at present by an expert school can be well realized by a study of the first fifty years of Gresham College, London. The merchants and traders of London, in the first flush of new-world discovery, turned to Sir Thomas Gresham's professors for their instruments of, and treatises on, navigation.

[2] It is not to be inferred that mechanics or biology is to be taught by medical men waiting for a chance to get on to the clinical staff of a hospital school. On the contrary, we want a specialized class of teachers, who devote their leisure to research in biophysics and kindred subjects. The mechanism of the jaw is quite as good an object-lesson in the fundamental principles of mechanics as the screw and the systems of pullies, while the principle of energy and the laws of elasticity are subject to variations in living forms which are apt to be overlooked by the pure physicist. The range of linguistic studies required for canon and mediæval law, for *Weisthümer* and folk-custom, are scarcely those of the academic classical scholar or the Teutonic philologist. Nor does the university philosopher find anything profitable between Aristotle and Descartes,—although it was the age of fathers and schoolmen, who directly or indirectly gave rise to all modern European philosophico-theological systems.

many cases but little used for clinical instruction. The medical schools thrive or not according to the success of their hospitals in attracting charitable subscriptions, and this again depends indirectly on skilful advertisement. The result is overlapping, rivalry, want of specialization, and the predominance of pecuniary instead of purely scientific interests. General municipal control of the whole hospital system must sooner or later be the rule, and with the wider clinical material thus placed at the disposal of medical instruction must come a diminution in the dominance of individual medical schools over individual hospital management. The overlapping of the preliminary teaching, and of much of the more theoretical and scientific branches of medicine and surgery, must be avoided. The direct and sufficient payment of all forms of medical teaching must attach men to academic work and experimental medical research as a profession, and such teaching not be undertaken as a step to a consulting practice. The competition of the medical faculties of different universities, and of the medical schools of the same university, would be perfectly healthy if it depended solely upon the reputation of the teachers; but it depends largely on the flow of public subscriptions to individual hospitals, the success with which the school may be used as a step towards a professional reputation, and the skill of one or two men in effective advertisement of the special wants of their individual hospital, or its special fitness to deal with a disease for the time looming large in the popular mind. The municipal control of the hospitals, the utilization of all clinical material, the wider separation of the academic teaching of medicine from its purely professional pursuit—these are the points which arise in the mind of one who views the present chaos from an outside standpoint. But if the observer be an outsider, he is a sympathetic one, who believes largely in the academic future of experimental and scientific medicine. Yet here the very instruments of knowledge (such as vivisection) and of experiment (like inoculation) demand the most careful and diplomatic procedure. The storms of the past in these matters are as nothing compared with what we may experience in the near future; and if sure progress is to be made, there must be no hasty adoption of tentative treatments, when no strong scientific arguments in their favour are adducible; there must be no "fishing" inquiries on living forms; in other words, each experiment sanctioned must be directed to answering a definite question, which in the opinion of scientifically trained minds there is reasonable hope might be answered by the investigation proposed, and, if answered, would be of substantial service to medical or surgical treatment. Lastly, a greater knowledge of the nature of scientific method and of scientific proof must in some manner be provided for by academic medical training.[1] Medicine, and even surgery, must to a large extent be, and remain, empirical; but it is just the empirical sciences in which, for example, an accurate theory of statistics is of most importance. It is not too much to say that medical statistics are at present in a most rudimentary condition; definite conclusions are over and over again drawn from short series of cases, where the trained statistician realizes that the emphasized differences are well within the limits of random sampling; or, again, A and C are found statistically to be associated with B, and it is argued that A and C must be themselves associated. The recent vaccination legislation has produced most instructive object-lessons in this direction. It has very unfortunately created a large class of men with pecuniary interests in the maintenance of vaccination. These men have had, in the press and at public meetings, to face a strong opposition, partly sceptical, largely fanatic. It is not too much to say that from the standpoint of science the medical defendants' handling of statistics has been excelled in inadequacy only by that of their opponents'. Much of the strength of proof in medical science depends entirely on statistics; copious raw material can be obtained from hospital practice, but this is rather too largely drawn from special classes of the community. The bulk of data from all classes either escapes written record, or remains "unstandardized" in case-books; here it is monopolized as "experience," when by co-operative action it might be statistically generalized into proof. The quantitative value of the correlation between environment, age, or physical characters and the special features or virulence of any disease is probably unknown at the present day in a single instance; and yet it is hard to conceive that clinical prognosis

Need for scientific method in medicine.

[1] In the course of the past twenty years the writer has received a scarcely intermitted flow of papers and letters from pseudo-scientists, circle-squarers, perpetual-motion mongers, heredity-theorists, neo-Darwinists, and others. The common feature of all these productions is the failure to grasp the elements of a real scientific *proof*. If the authors were classified by profession, the general medical practitioner would lead in numbers, the engineer being second, and the theologian a comparatively poor third.

would not be greatly advanced, especially among the younger members of the profession, by a quantitative knowledge of this kind. An authoritative body standardizing records, collecting individual experience and reducing it by adequate statistical theory, seems almost a necessity for medical progress at the present day. An elementary training in the handling of statistics and an insistance on the nature of scientific reasoning and statistical proof seems an urgent need, which ought to be, but is not, provided for in the preliminary scientific education of the medical profession.

Passing from professional schools[1] to the commercial university, we see at the present moment a great experiment being made in this direction. Birmingham has wisely entered on an unoccupied field.

The commercial university.

It may be desirable that one or, at most, two large centres should follow its lead, but it is most sincerely to be hoped that every university and university-college in the kingdom will not now appoint a professor of commerce and advertise a commercial department because they think it will pay. They have neither the funds nor the experience requisite for success. What is needed, from the national standpoint, is at most two or three perfectly efficient, fully manned, and fully equipped commercial universities, attracting students from the whole area of the empire. There are plenty of unoccupied fields for other institutions and colleges to specialize in, to the national profit, without the creation of innumerable small rivals in a new sphere. This is, of course, on the supposition that those who have first taken the work in hand will do it thoroughly, even if their progress be gradual and tentative at stages. Let it be remembered that it is not a mere professor of commerce that is required, but ultimately a staff of ten or a dozen such, with a large auxiliary force of lecturers and assistants. The man who can effectively deal with preferential tariffs and the general fiscal policy of the empire is not necessarily the man who has special knowledge of commercial interests and transit possibilities in China. A fundamental rule of the commercial university ought to be the "third free year" of the Russian academic system, and this means that only two-thirds of the senior staff will at any given time be actually engaged in teaching. The "third free year" is only free from teaching work; the lecturer is expected to travel for the purposes of research.[2] Especially, owing to the rapidly altering, ever contracting and developing, processes of commerce, will it be needful for the teacher to keep in touch with current progress and methods. Nor can a man rear men to be pioneers unless he has done pioneering work himself. It is a big task which the commercial university sets before itself, full of difficulties and, possibly, pitfalls, but one of essential national importance to-day, when our commercial leadership has been more than threatened. We have to rear a new type of worker, who will see in trade not only a source of individual profit, but a patriotic duty. Developing commerce on the Yangtse, or struggling against fever in West Africa, or starting new industrial enterprises in the Argentine, the trader must realize the relation of his efforts and those of his colleagues to thousands of handworkers at home, whose bread must come from over the sea by exchange. He must recognize that on his intelligence, on his linguistic and local knowledge, on his readiness to adapt goods and transit to environment, depends, to a far larger extent than has been dreamt of in the past, the national fitness to survive. The leeway of the nation has to be made up by increased intelligence, first in production and then both in distribution and exchange; the former need has to be met by higher craft-schools and improved technical colleges; the latter, by the creation of commercial universities. Can any training help the nation to the skilful merchant and the fully-equipped pioneer? Those who believe in education and modern scientific methods can only reply: Yes, if you train the intelligence by the heuristic method, and exercise it on the materials of its future work. It is a great task which Birmingham has set itself; let us hope that it realizes its magnitude and difficulty—above all, that it understands that failure, from want of efficient staff or of equipment, or from lack of internal or external enthusiasm, would be little short of a national disaster. It would discredit for years, if not indefinitely, the systematic training of intelligence in one of the most important fields of national activity.

[1] The range of professional schools wants considerable widening. One profession certainly ripe for a great professional science school is that of the actuaries, and a little study of official reports will show that a school for government statists is a necessity of a not distant future.

[2] Started in the commercial university, we might hope that this wise custom would extend to the pure-science, medicine, and engineering faculties, where it is as important to seek new material, test foreign methods, and critically examine current practice as in commerce.

Commercial universities, again, suggest the great importance of further extending the *Wanderjahre* custom. We have already discussed the need for local colleges, schools, and universities to specialize, and the advantage of the student wandering in search of his subject and the master-teacher. To the commercial university a relatively considerable number of studentships should be attached, the holders of which should be compelled to travel and report on foreign and colonial commercial methods and possibilities. These reports should in the first place be looked upon as exercises, but selected reports might well deserve publication as monographs of commercial research. Past holders of such scholarships, the pick of academic training, with their minds freed from insular method and local custom by the insight of travel, would undoubtedly be in constant demand for pioneer work. They would form a class such as is being rapidly formed in pure science[1] by the 1851 Exhibition scholars, men compelled to wander in search of research training. A percentage of failures there has been, and probably must be, but the next generation of physicists and chemists will undoubtedly show how markedly advantageous has been the system. The *Wanderjahre* with the research studentship must be widely extended to all fields of work. Any Oxford or Cambridge college which insists on its fellowships being held only on *Wanderjahre* research conditions will quickly realize the profit which must flow from the increased reputation of its members and the broadened views and activity of its fellowship-lecturers. The older universities can distribute their fellowships without the special limitations set in the case of the 1851 studentships to which we have already referred: they could yearly send out men to study the flora and fauna of almost untouched districts; to learn the native languages, religions, and customary laws of British and other possessions; to study under the masters of pure science, history, or philosophy who exist outside their own walls; and to return, as the American travelling fellows have done from the European universities, to develop their home institutions and widen their educational system by leaps and bounds. Without such *Wanderjahre* training, no academic post ought to be open to the teacher of the future.

The Wanderjahre.

III. *Science in the Direct Service of the State.*

A slender sketch like the present does not permit of our dealing at length with another class of science school of vital importance to the state, namely, *Government Schools* training directly for special branches of state service. Here the maximum efficiency possible both in staff and equipment is absolutely essential for national safety, and yet the routine, almost a necessity, of official institutions is excessively apt to check just the very variations of individuality and the genius on which discovery in science and progress in its practical applications almost invariably depend. For this reason it is very desirable that the government schools should be limited to those branches of instruction which are needed only for the national service. For example, schools of offence and defence—naval colleges, staff colleges, artillery and military engineering colleges; to these ought probably to be added, schools for home and imperial civil service—for consuls, native state residents, and the lower branches of the diplomatic service. It seems, but for the historic evolution,[2] a curiously anomalous process to select for many of the latter services men who have obtained examination distinction in classics and pure science, often taught by crammers, and with no special relation to the future work of the taught. It would probably be a great advantage to place these colleges, where feasible, near to one or other university. Thus while specialization in training and study should be insisted upon, both teachers and taught would have the widening influence of contact with other forms of work and play. The want of this "touch" undoubtedly tells on the efficiency of certain service colleges: their professors are too isolated; and necessary as is specialization, and valuable as is *esprit de corps*, the creation of a caste among the students, with caste habits and amusements, is far from an unmixed good. Without rivalry, and free from comparison with

Government schools.

[1] Comparatively few of these scholarships appear now to be given for essentially technical research,—which was possibly the original intention.

[2] The origin of the all-pervading state-examination system in the United Kingdom was the desire to check nepotism in government appointments; to hinder one type of inefficient is not equivalent to selecting the fittest and training them effectively for their specialized work. Even the examination system has probably been adapted, by artificial "adjustment of marks," to pass into the service not individuals, but types of men who appear best suited for the work in the eyes of certain commissioners. In other words, we are trusting very considerably to *personal* judgment as to a fit type; and this fact, be it good or bad, is screened behind a complex system of examination-marking.

any but foreign schools, the government service school is liable to run in grooves; in many cases the staff does not appear to be numerous enough or sufficiently specialized to have leisure or inclination to study new problems or foreign methods. The pay of a government professor and the honour of the position should be such as to attract the highest teaching and organizing talent to the state service, and the leisure at present sometimes devoted to external teaching and examination work should be monopolized for specialized research work in the national service.

Relation of government schools to technical colleges.

Lastly, the government schools should be confined to those branches of the service where the specialized training required by government servants is not already being provided on an adequate scale by other educational bodies. A government civil engineering college, for example, may be perfectly efficient in its own line, but the men it turns out see only one group of teachers and one form of instruction. The whole service may thus run far too much in one groove, which would be impossible if its members were the picked students of the various technical schools and universities. The same criticism applies, if to a less extent, to naval engineering and architecture. The Admiralty, which occasionally does draw on external supplies, rarely gets the best students of the technical colleges, because it draws by an examination schedule which none of the more efficient engineering schools would be likely to adopt for its curriculum; and if they did, it would be, under present arrangements, devoting their energies to a small and very uncertain class of student. It would be an interesting experiment—and we believe a successful one—if the government gave for a trial number of years a limited number of engineering appointments to the pick of the technical college students, and compared their work with that of the men reared in their own schools. We believe that the wider field of selection would lead to a greater variety in capacity, talent, and training being made available for the government service.

Government research institutes.

From government schools we naturally pass to government research institutions, and the position of science as consultant in the modern state. The position accorded to science in the past in this respect has been a very defective one. The state needs quite as much scientific as legal advisers; indeed, under present circumstances, they are perhaps even more essential. Not only problems in offence and defence, but in development, transit, industry, disease, sanitation, reproduction and medico-legal matters arise daily, and the government wants not only to know where to turn for immediate advice, but to be sure that it will get what for the great bulk of cases is *sound* advice. Beyond this, the progressive state ought always to be on the look-out for and seeking to encourage discoveries or inventions which will increase national efficiency either for war or in peace. Something of this latter function may be fulfilled by permanent government research institutions and consultative scientists. But not only is the incentive to discovery greatest in the young man with his future to make, but the power to discover great things rapidly diminishes with age. There is the born scientist, who researches for the keen intellectual pleasure of the work, and would go on, whatever his income or post; and there is the man for whom research or science is a means to a living and a position. He pursues it to a competency and his D.Sc., to his F.R.S. or to his K.C.B., as the desire impels. He retires on his laurels, spending his life on committees, emphasizing the needs of pure science, the importance of technical education, and scaring us with the German bogie.[1] It would be unreasonable to condemn this man; for he belongs to the type which forms the bulk of humanity, whether occupied with science or any other pursuit. He has probably done good work, and his experience is of value for consultative, if no longer for research, purposes. We have only to remember that science has and can have no high priests, for it is always progressive and advancing. It is hardly too much to say that the moment a scientist reaches celebrity as a man, he has ceased to be a discoverer. For he can hardly attain fame before middle life, and already the younger man is on his shoulders reaching higher, for he starts with his elder's knowledge and with the unspent energy of youth. One of the greatest dangers of science, and especially science in the consultative service of the state, is the possible creation of a scientific

The two scientific types.

[1] All honour to Germany's scientific work! Her specialist has organized his science and made research a trade, yet his product lacks too often the real insight, the lucidity, the touch of genius characteristic of the best French work; rarely, too, does the German break entirely novel ground, as was done by the three great scientists of the English type—Newton, Faraday, and Darwin.

hierarchy, resting on past achievement and believing itself at the summit of scientific knowledge. As soon as a man ceases to research, he has fallen behindhand; his tools grow rusty, and he ceases to grasp new methods and new possibilities. Hence one of the greatest problems of the state is how to draw into its service not only those who have achieved as consultants, but those who are achieving as discoverers. Possibly an extension to our country of the French system of substantial pecuniary prizes, with not too-closely defined limitations, would turn more of the research work of the country to national ends. A prize every two or three years of four or five thousand pounds for a markedly useful contribution to the country's means of naval defence; a like sum for the most valuable work tending to develop the chemical industries of the country, or to improve its sea or land transit; or, again, equally substantial prizes for medical or sanitary discoveries—these would draw the energy of many youthful scientists into channels of national value. A yearly government offer, not necessarily an expenditure, of £10,000 to £20,000 in such prizes would be no extravagant sum, and might well have enabled this country to lead in at least some of the recent fields of discovery, such as smokeless powders, submarine boats, motor cars, wireless telegraphy, &c. &c. Such prizes and research should be independent of national laboratories and government consultants, to whom more specialized problems and routine difficulties should be submitted for solution or advice. In the one case the appeal is made to the energy of the youthful scientist, in the other to the experience of the consultant, to the store of current knowledge.

Prize system.

Considering more closely science institutions in the direct service of the state, it will be found that the ideas of men on this point are at present somewhat chaotic. Such institutions as exist have arisen partly from the immediate exigencies of executive, and partly from the outside pressure of pure scientists, asking for government assistance, or for public support on the ground of a private institution fulfilling a crying national need. This haphazard origin accounts for the want of organization and specialization; private institutions are partially doing national work, and national institutions which should be doing specialized industrial work have fallen to some extent into the hands of pure scientists. Here, as in other fields, a differentiation of pure and applied science is necessary. It is perfectly true that none can tell how soon a result of pure science will be applicable to industry; but the type of mind that can apply such results is rare, and the bulk of applied science problems are first formulated, and afterwards the extension of pure science which leads to their solution worked out.[1] In the first place, therefore, a nation needs laboratories for its industries—for standardizing the implements, testing the materials, and distributing knowledge with regard to the processes of its manufactures. There must be institutions which, free of every bias, will test and compare the products of all manufacturers seeking government contracts, or will advise Boards of Trade and state or municipal authorities as to regulations for factories, transit, food, and sanitation. These needs stretch far beyond any existing institution, and cannot be satisfactorily dealt with except by technical specialists having control of independent laboratories.

State science institutes.

Thus the nation's wants comprise: (i.) *National Engineering Laboratory.* — This must be subdivided into mechanical, civil, and naval departments. The first would test materials and machinery for government use, or apply standard tests in the case of corporations or private individuals. It should keep a hold on the industries of the country by reports on the quality of materials of construction bought in the open market, and their quality relative to foreign productions. It should undertake engine and other tests for manufacturers, and report to them on the relative efficiency of British and foreign machinery. In fact, in every way within its sphere it should apply and circulate current knowledge. The second, or civil engineering department should deal in a like manner with docks, railways and general transit, water and sewerage, &c. It should be prepared to advise the government or municipalities on the conditions to be satisfied in bridge structure, to criticize development plans from the national and from local standpoints, to provide tests for dam efficiency, data for the flow of fluids, and a multitude of other matters which come daily before civil and municipal engineers. The naval depart-

National engineering laboratory.

[1] Of course this rule is not universal, but it is strikingly illustrated in pure and applied mathematics. Developments of pure analysis are now and then of occasional use, but pure mathematics has over and over again been enriched by analysis directly invented for the solution of special physical or even technical problems.

ment should lay down the conditions for testing the machinery of ships, the strength of their plating and riveting, and keep shipbuilders in constant touch with foreign developments, as well as help to maintain a high standard of efficiency in home work. It should assist indirectly or directly in the registration or classification of ships. Of course much of all this is done at present by various government inspectors or departments, by private corporations like the two Institutions of Engineers and Lloyd's. But it is not done in a systematic manner. When a pressing need arises, a commission is appointed, which investigates or experiments for a time on iron, boilers, or bridges. It has to do this in a more or less haphazard sort of way, with a temporary staff, and without a properly equipped centre, or even without direct experiment by comparing the conflicting evidence of too often interested witnesses. These defects of existing procedure result in grave delays, much expense, and general inefficiency. A trained staff accustomed to experiment, with apparatus and locus provided, ought to be at the constant service of such commissions; in many cases such a staff would be already prepared with the unbiassed information necessary for a judgment, and would be the centre from which government and private individuals could at once ascertain what was known here or abroad on the problems ever arising in progressive construction.

Electro-technical laboratory.

(ii.) In close touch with the Engineering Laboratory should be a *Laboratory for Electro-Technical Industries.* This is especially needful in the case of electric transit. But electro-technology opens up such an immense field of activity in transit, lighting, telegraphy, telephony, power, and the smaller arts, that the laboratory ought to be differentiated from that for engineering proper. Here there is at present such a wide amount of work necessary in standardization, testing, regulation, and control for public safety, that the early establishment of such a laboratory is almost more urgent than that of any other.

National chemical laboratory.

(iii.) It seems almost unnecessary to discuss the importance of a *National Chemical Laboratory.* This is to some extent already provided for in separate government departments. What is needed is centralization, departmental differentiation, and complete and efficient equipment. It must be in no sense an institute for research in pure science, but it has to answer the innumerable chemical problems of the state, both on the organic and inorganic sides. It must do for the chemical industries what the engineering laboratory does in its own field—standardize, test purity, report, and watch foreign rivals; deal with colonial produce, poisons, adulteration of food, and an infinity of other problems, which suggest many sub-departments, and ultimately differentiation into separate national institutes.

National institute for the smaller industries.

(iv.) There must be at least one institute to deal with those smaller industries which demand a high standard of scientific efficiency. The work done in the old Kew Laboratory was excellent of its kind, and kept fairly in view the industrial factor; the testing of watches, chronometers, barometers, and thermometers must be supplemented by work on microscopes, theodolites, telescopes, and a multitude of optical instruments used in pure or applied scientific work. The Admiralty or War Office should know at once where to turn for a report on telescopes or telemeters, and upon the reliability of instrument makers, here or abroad. Nor does the above list by any means complete the round of important smaller industries where scientific control, standardizing, testing, or advice is desirable. As the scientific training of the nation, from the handworkers to the organizing leaders of each specialized industry goes on, the need for national institutes, as centres for collecting information, for maintaining high standards of production and controlling the relations of industry to the state, will grow more and more pressing, and the differentiation of the above institutes and the foundation of new ones must be taken in hand. It will be clear that it is not possible to deal satisfactorily, from the industrial side, with such consultant bodies as we have sketched when they are merely sub-departments of a National Physical Laboratory. They must be placed in the hands of leading and independent *technical* authorities.

(v.) *National Astronomical Observatory.*

(vi.) *National Meteorological Office.*

(vii.) *National Geographical and Geological Survey Office.*

The institutes comprised under (v.), (vi.), and (vii.) have been for years in effective existence, but perhaps have hardly been developed on a sufficiently wide or imperial basis. The link between the central

home observatories and those in the colonies and dependencies has hardly been strong enough, nor the whole chain of institutes systematized; and this is particularly the case in the meteorological service. There is no central authority for collecting and storing the meteorological data of the empire. In some cases records are taken at scientifically important stations, but no returns are made, still less printed. Often months or years of record will be omitted. In other cases returns are made by the naval authorities, by the army medical service, by colonial botanical superintendents, &c. &c., and returns have to be sought for at the Admiralty, Netley, Kew, or vainly at the Colonial Office. Colonial data, unless printed, rarely reach this country, which from the imperial standpoint is far behind Portugal in the systematization of its meteorological service. It must never be forgotten that the meteorological condition of the world at any given time is a complex unity, and the state of the atmosphere in Northern Norway is correlated with the contemporary conditions even of St Helena and the Cape. The world-wide extent of the British Empire presents opportunities in this direction which are far from utilized at the present time, and the extension and "imperialization" of all three of the institutes just referred to must be an important task for the immediate future.

Further national institutes of science.

Meteorological service.

Thus far we have dealt chiefly with the inorganic or physical sciences *applied* to the service of the state. In several of these sciences there have been, and undoubtedly will in future be, demands for state institutions for research in pure science. Now although the boundaries of pure and applied science are in some cases ill-defined, yet we believe a working distinction can be made, especially if we remember that the first, if not, however, the whole function of a national institute is to collect data and apply existing knowledge. It is to the academic bodies that we should look for real advance in pure science, and this will become the more feasible the sooner it is recognized that it is the function of these bodies to teach by research, and that the members of their staff who merely teach and do not research are not teaching in the proper manner. Hence any cry for national laboratories for pure science must weaken the legitimate demand of the universities for effective municipal and state support for their laboratories. The university laboratories for research and post-graduate students are, and ought to be, the true national laboratories for pure science. Of course they want, especially on the biological side, wide extension and development.

The state and pure-science institutes.

Turning now to the organic side, we see at once the fundamental importance of: (viii.) *National Institute for Preventive Medicine* and (ix.) *National Institute for Sanitary Science.*—Here again there are innumerable questions to which municipalities, or home and colonial governments, need answers, and definite and prompt answers. It is little good, after an army has been decimated by enteric, to appoint a commission to inquire into the causes of it: advice and control on the point should have been provided before the army started. Pollution of rivers, provision of vaccine and antitoxin, the treatment of malarial districts, are not topics to be left on one side until public attention forces the government to action; they and many other matters are not effectively dealt with by private corporations, individual research, or hurriedly constituted commissions; the staff of government institutes should have been steadily pegging away at them, collecting data and experimenting, so as to be ripe with information when the state demands aid, or popular interest, tardily excited, calls for expert opinion.

Medical and sanitary institutes.

(x.) *National Institute for Anthropology.*—With possibly more races under the British flag than under any other imperial symbol since the days of the Roman eagle, we have yet entirely failed to systematize and nationalize our study of those races. There is no national museum or institute where one may learn the cranial, anthropometric, and physical characters of the various races under our sway, still less something of their languages, folk-customs, industries, and religions. An institute carrying out a complete anthropological survey of the empire is as necessary from the imperial standpoint as those dealing with the geographical or geological surveys. The Americans have recognized this, and their anthropological reports and museums under state supervision will soon be a model for such work everywhere.

National institute for anthropology.

(xi.) *National Institute for Botany.*—The importance of this has been long recognized, and Kew with its associated botanical gardens in the colonies and dependencies forms a great organization which

better security for the publication of first-class work than can be provided even by a strong editorial committee in a specialized branch of science.

Need for specialization in scientific journals.

If we demand for scientific journals and societies permanent endowment, we must also demand from them increased specialization, and in many cases a higher standard of publication. At present memoirs of a given class may appear in perhaps a dozen different journals or proceedings. We may hope in the future that national journals may assume a more international character, and then specialization would become more and more feasible.[1] Such specialization is needful, not only for the efficiency of editorial committees, and for the facility of reference, but would ultimately extend circulation. A specialist will take in one or two journals devoted to his own branch of science, but he cannot afford a round of publications which partially and intermittently touch his special field. He trusts to the library rather than to the study shelves, and thus the total number of subscribers to scientific literature is permanently reduced.

Co-ordination of existing learned societies.

The progressive specialization and differentiation of learned societies are of course familiar to every student of the formal history of science, and it becomes a grave question how long national academies and royal societies can maintain their old lines of publication or constitution. Under the present arrangement the most highly specialized and, perhaps, the best work does not reach these societies at all; and the leading specialists may be far more interested in the work and executive of special societies or journals for astronomy, biology, or geology, than in those of the academy or society which is supposed to be the representative of national science. It weakens the reputation of the leading society to publish special memoirs distinctly inferior to those issued by a specialized society or journal;[2] it is undesirable, on the other hand, that the leading society should skim the cream of special journals and transactions, if indeed it lie in its power to do so. The co-ordination of learned societies and the organization to a common end of their publications is a matter of some difficulty, but of a pressing character. It may be doubted whether a central society, discussing and publishing communications bearing on almost every field of knowledge, is fitted to survive in the highly specialized science of the future. Rather such a central society needs differentiation into astronomical, mathematical, physical, biological, geological, physiological, and other sections, each of which is now more or less effectively provided for by one or more special societies. In our own case we might render the whole work of science much more effective if the publications of these societies—proceedings and transactions—were rendered uniform in format, and the first stage to publication[3] by the Royal Society, or to its membership, were through these specialized or co-ordinated societies. In this way a much higher standard of publication and of membership might be reached, especially if the executive of the central society were a body fully representative of the executives of the co-ordinated societies. Thus the Royal Society's *Transactions* and *Proceedings*, off-printed from the sectional publications, would embody the best and most representative scientific work of the nation; this selection, embracing most of originality and progress in the year's scientific work, would be offered as an incentive in style and matter to individual workers, and as a résumé of the best in national work for international criticism and exchange. Whatever direction reform of the Royal Society and co-ordination of existing scientific bodies may take, it is hardly possible that by the middle of this century the Royal Society can remain with its present *olla podrida* in publication and membership, and yet maintain its reputation or influence.

V. *State Recognition of Science.*

We have already referred to a more or less fundamental distinction that exists between the two types of scientific workers,—those who adopt science and research as a profession, and those who are impelled to

[1] There are, for example, perhaps a dozen journals of mathematical research, of which at least five or six are of the first class. But each one covers the enormous range of pure and applied mathematics, and a mathematical paper may have to be hunted for not only in these, but in twice as many more proceedings or transactions. Both pure and applied sides require to-day in publication (as in teaching) wide-reaching differentiation, and a specialization of mathematical journals on international lines would be a great gain.

[2] The mixed character of the papers communicated, even at a single sitting, to a national academy or society makes a really valuable discussion, such as may well arise in a specialized society, rarely possible.

[3] It would be needful to maintain a general publication, co-ordinate with those of the specialized societies, for work in new fields—often the most important type of work—not yet recognized as a part of any differentiated section.

investigate by an uncontrollable curiosity, to which in our higher flights we are tempted to give grandiloquent names. As in other callings, so in science the bulk of men, from forces of external circumstance and of internal character, must belong to the first class, and the usual incentives of endowment and state recognition are needful as spurs. The state of the future, the welfare of which will so largely depend on science, must provide such rewards of this kind as seem necessary. In this respect the institution of a particular grade, say that of State Science Counsel, with a patent like that of the existing King's Counsel, might serve to mark the field in which distinction had been gained, and so differentiate scientists as a class from provincial mayors and successful financiers. The whole body of State Science Counsellors might form the State Science Council. This would consist of the directors of the national institutes, of the most distinguished pure science professors in the universities, of the leading teachers in the principal technical and government schools, and of any other persons of great scientific achievement. It would form the chief scientific consultant body to which government or any public authorities could appeal in cases of difficulty. Out of the members of such a council, investigating and advising commissions might be nominated by ministers of state. It would probably be undesirable to summon such a Science Council as a whole, or give it officers or corporate existence. Many of its members at any given time might be beyond active scientific work, but, as in the case of other state councils, selected members only might be summoned for special committees and special types of work. It would provide a body from which men far better able to advise the state could be drawn, than the council of any existing society. For it would involve specialists in all branches of pure and applied science, having the instruments of research at their disposal, and would be essentially practical and national in its character. But in the selection of the right type of man to aid the state in a particular function, we come back to the point from which we started—to a knowledge wholly different from scientific knowledge. Science in the end, if it is to be of the highest national service, must be subject to a different type of knowledge—to that experience of men, that power of selecting the fit man for the fitting task, which is summed up in statecraft. We need men in every department of state who have insight into character, who can judge the man who is capable of achieving, without having studied his creative work or knowing the "ropes" of his special science. Herein the position of science in both Germany and France is better than in Great Britain, for there is a closer association of the scientific and governing castes; we do not want an increase in the number of parliamentary scientists, for in deserting science they have not become statesmen. It is a matter where closer personal knowledge and a more intimate contact of men of diverse pursuits have to be brought about. Such considerations lead us again to the training of statesmen; it seems far easier to develop the scientific knowledge of a nation than to increase its store of statecraft. Educate intelligently the craftsmen who form the basis of social life and the bulk of the electorate; then, perhaps, the politician who appeals to them will need to reach a higher standard; he, in his turn, will demand graver qualities and more weighty capacity in his leaders than at present: power of organization, insight into character, true executive ability, will weigh more than ready repartee, mere force in verbal criticism, or the other special aptitudes developed by a parliamentary training. But it is a long way up from nature-study in the village schools, and the heuristic method in craft-schools, to this; it may sound paradoxical to some, and a counsel of perfection to many. Yet the nation, from the bottom to the top, has yet to learn that trained intelligence in all functions is the factor which makes for victory in the modern international struggle. It may be a lesson taught by the wisdom of statesmen, or bitterly by the stress of defeat and famine. We have by one or other process to learn the national importance of science: to realise that science in the broadest sense, as educator and discoverer, is the mainspring of modern national life; that the future is to the scientifically trained nation which reproduces itself, maintains its health, develops its institutions, controls its production, organizes its distribution, extends its territory, governs its subject races, and prepares its offensive and defensive services with scientific foresight and insight—

State science counsel.

Science and statecraft.

> In the reproof of chance
> Lies the true proof of men—

and, we may add, the true proof of nations.

ENCYCLOPÆDIA BRITANNICA.

NEW VOLUMES.

Pribiloff Islands, often called the Fur Seal Islands, a part of the U.S. territory of Alaska, lying in Bering Sea in about 56° 50′ N. and 170° W. They were first sighted in 1767 by Synde, but visited by Gerasim Pribiloff in 1786, who discovered the fur seal rookeries for which they became famous. Between 1786 and 1890 it is estimated that 6,500,000 seal-skins were taken on the islands; and during the period of the first lease by the Government of the United States (1870–90) the lessees paid to the Treasury $5,956,565. There are two principal islands, St Paul and St George, about 30 miles apart, and Otter and Walrus islets near St Paul. The Aleuts employed in the fishery number about 400, and only agents of the United States or employés of the lessees are permitted on the islands. The islands are hilly and volcanic, without harbours, with abundant herbage, a mean annual temperature of 35·7° F., and a rainfall of about 35 inches. The total area of the group is about 50 square miles.

Příbram, town and capital of a district of the same name, Bohemia, Austria, 29 miles east by south of Pilsen. It is the most important silver-mining town in Austria, the rich Adalbert vein having been worked continuously since 1778 and now reaching a depth of over 3300 feet, becoming richer with the depth. Population (1890), 13,412, or, including the adjoining township of Birkenberk, 18,536; (1900), 19,119, almost exclusively Catholic and Czech.

Price, Bartholomew (1818–1898), English mathematician and educationist, was born at Coln St Denis, Gloucestershire, in 1818. After a private early education he matriculated at Pembroke College, Oxford, of which college (after taking a first class in mathematics in 1840 and gaining the University mathematical scholarship in 1842) he became fellow in 1844 and tutor and mathematical lecturer in 1845. He at once took a leading position in the mathematical teaching of the University, and published treatises on the *Differential Calculus* (in 1848) and the *Infinitesimal Calculus* (4 vols., 1852–60), which for long were the recognized text-books there. In 1853 he was appointed Sedleian professor of natural philosophy, a post which he filled for forty-five years, resigning it in June 1898. His chief public activity at Oxford was in connexion with the Hebdomadal Council, in which he was very prominent, and the Clarendon Press, of which he was for many years secretary. He was a man of remarkable business ability as well as great diligence, the result of this being that he became largely responsible for the conduct of the affairs of the University in various directions. He was also a curator of the Bodleian Library, an honorary fellow of Queen's College, a governor of Winchester College, and a visitor of Greenwich Observatory. In 1891 he was elected Master of Pembroke College, which dignity carried with it a canonry of Gloucester Cathedral. He died on 29th December 1898. (R. F. S.)

Price, Bonamy (1807–1888), political economist, was born at St Peter's Port, Guernsey, on 22nd May 1807. He was educated privately, and then entered at Worcester College, Oxford, in 1825, where he took a double first in 1829. From 1830 to 1832 he was mathematical master, and from 1832 to 1850 a classical master, at Rugby. After resigning his position there, he lived for some years in London, and was appointed, both then and later, to serve on various Royal Commissions. He married in 1864. In 1868 he was elected Drummond professor of political economy at Oxford, and, proving himself an excellent lecturer, was thrice re-elected to the post, which he held till his death. In 1883 he was elected an honorary fellow of his college. He died in London on 8th January 1888. His principal economic publications, exclusive of pamphlets, were: *The Principles of Currency* (1869), *Currency and Banking* (1876), *Chapters on Practical Political Economy* (1878).

Priego de Cordoba, a town of Spain, in the province of Cordoba, in a plain bounded on the south by the sierra of the same name and by Rute. The surrounding

districts send to the market large droves of cattle and mules, and agricultural products, especially wine and oil. The local industries, tanning and manufactures of esparto grass, rugs, and cotton goods, are on the increase. The streets and squares are well built and mostly modern. The parish church was built in the 13th century and subsequently restored; it has a fine chapel. There are several other churches and convents. The town-hall, theatre, and public promenades are modern. There are ruins of an old castle—Priego having been a fortified city of the Moors, and twice retaken by the Christians in 1226 and 1407. Population (1897), 14,434.

Priluki, a district town of Russia, in the government and 145 miles north-west of the town of Poltava. It is an old town, and is mentioned in the will of Vladimir Monomakh. It belonged for some time to the Poles, but was definitively annexed to Russia in 1781. It has an agricultural society and two steam flour-mills, and carries on trade in grain and flour. Population (1897), 19,055.

Primrose League, The, an organization for spreading Conservative principles amongst the British democracy. The primrose is associated with the name of the late Lord Beaconsfield (*q.v.*), as being preferred by him to other flowers. In a letter to his private secretary, Mr Montague Corry, afterwards Lord Rowton, he once wrote: "Primroses are beginning to show themselves at Hughenden, 'sweet harbingers of Spring.'" On a card affixed to the wreath of primroses plucked in the Isle of Wight, and sent by Queen Victoria to be placed upon his coffin by Prince Leopold, there were written in Her Majesty's own handwriting the following words: "His favourite flowers: from Osborne: a tribute of affectionate regard from Queen Victoria." On the day of the unveiling of Lord Beaconsfield's statue, Sir Henry Drummond Wolff, coming late, found all the members of the Conservative party in the House of Commons decorated with the primrose. A small group had for some time discussed the means for obtaining for Conservative principles the support of the people. He therefore said to Lord Randolph Churchill, "Let us found a primrose league." The idea was accepted by several gentlemen in the habit of working together, and a meeting was held at the Carlton Club shortly afterwards, consisting of Lord Randolph Churchill, Sir H. Drummond Wolff, Mr (afterwards Sir John) Gorst, Mr Percy Mitford, Col. Fred Burnaby, and some others, to whom were subsequently added Mr Satchell Hopkins, Mr J. B. Stone, Mr Rowlands, and some Birmingham supporters of Col. Fred Burnaby, who also wished to return Lord Randolph Churchill as a Conservative member for that city. These gentlemen were of great service in remodelling the original statutes first drawn up by Sir H. Drummond Wolff. The latter had for some years perceived the influence exercised in benefit societies by badges and titular appellations, and he further endeavoured to devise some quaint phraseology which would be attractive to the working classes. The title of Knight Harbinger was taken from an office no longer existing in the Royal Household, and a regular gradation was instituted for the honorific titles and decorations assigned to members. This idea, though at first ridiculed, has been greatly developed since the foundation of the Order; and new distinctions and decorations have been founded, also contributing to the attractions of the League. The League was partially copied from the organization of the Orange Society in Ireland, which does not include either Roman Catholics or Jews, who had then recently proclaimed their support of the Conservative party. Thus it was considered that the Primrose League, embracing all creeds and classes, would have much influence in organizing public opinion. In lieu of calling the different subsidiary associations by the ordinary term "Lodges," the name was given of "Habitations," which could be constituted with thirteen members. These were intended as a substitute for the paid canvassers, about to be abolished by Mr Gladstone's Reform Bill. It was thought that thirteen in the habit of working together would be sufficient to undertake the registration and canvassing of a district. The principles of the League are best explained in the declaration which every member is asked to sign: "I declare on my honour and faith that I will devote my best ability to the maintenance of religion, of the estates of the realm, and of the imperial ascendancy of the British Empire; and that, consistently with my allegiance to the Sovereign of these realms, I will promote with discretion and fidelity the above objects, being those of the Primrose League." The motto was "Imperium et libertas"; the seal, three primroses; and the badge, a monogram containing the letters PL, surrounded by primroses. Many other badges and various articles of jewellery have since been designed, with this flower as an emblem.

A small office was first taken on a second floor in Essex Street, Strand; but this had soon to be abandoned, as the dimensions of the League rapidly increased. Ladies were generally included in the first organization of the League, but subsequently a separate Ladies' Branch and Grand Council were formed. The founder of the Ladies' Grand Council was Lady Borthwick (afterwards Lady Glenesk), and the first meeting of the committee took place at her house in Piccadilly, on the 2nd March 1885. The ladies who formed the first committee were: Lady Borthwick, the Dowager-Duchess of Marlborough (first lady president), Lady Wimborne, Lady Randolph Churchill, Lady Charles Beresford, the Dowager-Marchioness of Waterford, Julia Marchioness of Tweeddale, Julia Countess of Jersey, Mrs (subsequently Lady) Hardman, Lady Dorothy Nevill, the Honourable Lady Campbell (later Lady Blythswood), the Honourable Mrs Armitage, Mrs Bischoffsheim, Miss Meresia Nevill (the first secretary of the Ladies' Council). Miss Nevill soon achieved a considerable reputation by her activity and her oratorical gifts. The work of the ladies' branch consists principally in the distribution of literature, the organization of social entertainments with an admixture of politics, and in constant assistance as district visitors both in registration and in canvassing during elections.

When the League had become a success, it was joined by Lord Salisbury and Sir Stafford Northcote, who were elected Grand Masters. Since the first formation the numbers have increased to a marvellous extent, and the following table shows the annual progress:—

Year.	Knights.	Dames.	Associates.	Total.	Habitations.
1884 . .	747	153	57	957	46
1885 . .	8,071	1,381	1,914	11,366	169
1886 . .	32,645	23,381	181,257	237,283	1200
1887 . .	50,258	39,215	476,388	565,861	1724
1888 . .	54,580	42,791	575,235	672,606	1877
1889 . .	58,180	46,216	705,832	810,228	1980
1890 . .	60,795	48,796	801,261	910,852	2081
1891 . .	63,251	50,973	887,068	1,001,292	2143
1892 . .	65,149	52,914	957,180	1,075,248	2188
1893 . .	66,570	54,623	1,010,628	1,131,821	2233
1894 . .	67,896	56,147	1,074,388	1,198,431	2275
1895 . .	69,167	57,632	1,133,009	1,259,808	2296
1896 . .	70,475	59,117	1,185,536	1,315,128	2326
1897 . .	71,563	60,484	1,244,381	1,376,428	2346
1898 . .	72,590	61,817	1,295,612	1,430,019	2360
1899 . .	73,566	62,942	1,338,844	1,475,352	2371
1900 . .	74,461	64,003	1,380,097	1,518,561	2380
1901 . .	75,260	64,906	1,416,473	1,556,639	2392

The Primrose League has undoubtedly exercised considerable influence on elections. Much information may be found in an article in a review called *The Albemarle* of January 1892, written by Miss Meresia Nevill; and in the *Primrose League Manual*, published at the offices at Westminster. The latter publication shows that the League wishes for the dissemination of its three great principles, independently of party politics, and it contains at length the statutes and general instructions, with the gradation of honours and the financial arrangements. It is interesting as a history of the organization. (H. D. W.)

Prince Edward Island, a province of the Dominion of Canada, lies between 45° 58′ and 47° 5′ N. and 62° and 64° 27′ W. The rocks consist of soft red micaceous sandstone and shales, with interstratified but irregular beds of brownish-red conglomerates containing pebbles of white quartz and other rocks. There are also beds of hard dark-red sandstone with the shales. Bands of moderately hard reddish-brown conglomerate, the pebbles being of red shale and containing white calcite, are seen at many points; and then greenish-grey irregular patches occur in the red beds, due to the bleaching out of the red colours by the action of the organic matter of plants. Fossil plants are abundant at many places. These characteristics are persistent over the whole island, and the rocks have been assigned to the Permian age, but it is probable that outliers of Triassic rocks also occur. North of Summerside the land nowhere rises more than 175 feet above sea-level; but a considerable area lying between Summerside and Charlottetown, especially near North Wiltshire, is hilly, rising in places nearly 400 feet and containing the highest land on the island. From Charlottetown eastwards the land is comparatively low and level. The average mean temperature for 1899 was 43° F., the lowest being 10° and the highest 86°; the average rainfall for twenty-seven years (1874–1902) was 31·7 inches, and the snowfall for the same time was 92·7 inches. The area of the island is 2184 square miles. The population in 1871 was 94,021; in 1881, 108,891; in 1891, 109,078; and in 1901, 103,259, giving a density of 47·2 inhabitants to the square mile. In 1901 there were 18,746 families, with an average number of 5·5 persons per family. There were 51,959 males and 51,300 females. In 1901 the origin of the people was—Scots, 41,753; English, 24,043; Irish, 21,992; French, 13,867; all other nationalities, 1604. Of the whole population 103,126 were either born in Canada or became naturalized citizens.

Constitution and Government.—In 1892 the Legislative Council was abolished. The present Legislative Assembly consists of 30 members, who sit and vote together, though divided into 15 councillors and 15 assemblymen. The latter are elected by manhood suffrage, and the former by voters who own real estate valued at $325 or over. The province is represented in the Dominion House of Commons by 5 members instead of 6, as formerly.

Religion.—The principal religious denominations and the number of their adherents were as follows (1901):—Church of England, 5976; Church of Rome, 45,796; Presbyterians, 30,750; Methodists, 13,402; Baptists, 5905.

Education.—In 1901 there were 475 schools conducted by 589 teachers; pupils enrolled, 20,779; percentage of attendance, 59·34. The total amount expended for education was $164,935, the cost per pupil enrolled being $7.93.

Finance.—The ordinary revenue in 1901 was $284,431, and the ordinary expenditure $315,326. In 1901 the gross debt was $642,178, and the assets $181,953.

Defence.—The active militia consists of one regiment of garrison artillery, one company of engineers, one battalion of infantry, and a squadron of Canadian mounted rifles—a total of 58 officers and 713 non-commissioned officers and men, and No. 8 Field Hospital Medical Corps.

Agriculture.—Within the last ten years of the 19th century a great impetus was given to the manufacture of butter and cheese by the introduction of the co-operative plan. In 1899 there were 34 cheese factories and 30 creameries, which produced 3,746,168 ℔ of cheese valued at $376,060, and 722,614 ℔ of butter valued at $139,056. The rapid development of this industry will be seen from the fact that in 1892 there was only one factory, producing 63,018 ℔ of cheese valued at $7872; and in 1894 only 2 creameries, producing 44,512 ℔ of butter, valued at $7872. The island is famous for the excellent quality of its dairy products. In 1891 the crops raised were wheat, 613,364 bushels; barley, 147,880; oats, 2,922,552; rye, 221; peas and beans, 7180; buckwheat, 84,460; corn, 2651; potatoes, 7,071,308; turnips, 2,005,453; grass and clover seed, 12,417; and hay, 132,959 tons. The total number of occupiers of land was 15,137; of these, 14,295 were owners, 813 tenants, and 29 employés. There were 1,214,248 acres occupied, 718,092 improved, 536,175 under crop, 178,072 in pasture, 496,156 in woodland and forest, and 3845 in gardens and orchards. In the same year there were animals and their products: horses, 37,392; milch cows, 45,849; other horned cattle, 45,730; sheep, 147,372; swine, 42,629; domestic fowls, 534,962; cheese, 123,708 ℔; butter, 1,969,213 ℔; wool, 528,273 ℔.

Fisheries.—The Dominion Government distributes annually $160,000 among the fishermen and fishing vessels of Canada; of this amount Prince Edward Island received $10,589 in 1900, distributed among 29 vessels of 737 tons and 1140 boats with 2198 men. In the same year the total number of vessels employed in the fisheries was 29 of 750 tons and 2330 boats manned by 4895 men. The value of vessels, boats, nets, lobster canneries, &c., used in the whole province was $442,120. The total value of the fisheries was $1,059,194, of which lobsters amounted to $445,417, herring to $147,347, oysters to $71,300, and cod to $155,038.

Manufactures.—Factories have been established for the manufacture of tobacco, boots and shoes, cream cheese, condensed milk, and pork-packing. In 1891 there were 2679 industrial establishments: capital invested, $2,911,963; hands employed, 7910; wages paid, $1,101,620; value of raw material, $2,092,067; value of articles produced, $4,345,910. The volume of trade during the last quarter of the 19th century is shown in the following table:—

Year.	Exports.	Imports.	Entered for Consumption.	Duty.
	$	$	$	$
1875 . . .	1,308,461	1,960,997	1,983,419	317,163
1885 . . .	1,494,469	780,141	778,444	187,642
1895 . . .	1,039,493	524,133	530,713	136,136
1900 . . .	1,349,529	502,565	506,374	143,402
1901 . . .	681,403	526,617	543,130	148,258

Shipping.—The registry books of the Dominion for 1900 showed that Prince Edward Island owned 176 sailing ships and steamers, net tonnage, 14,251; of these 21 were steamers, gross tonnage, 3966. During the same year there were 3 vessels built, net tonnage, 106.

Communication.—Two specially constructed boats ply between Georgetown and Pictou, and, with slight interruptions in extremely cold weather, make regular trips. The mail is now carried in this way instead of by ice-boats, as formerly. During the winter of 1901–02 experiments with one of these steamers were carried on between Cape Tormentine, N.B., and Prince Edward Island ports. These experiments showed that communication can be kept up the whole winter. A complete telephone system extends over the island, connecting all the towns, villages, and the more populous country districts. In 1901 there were 209 miles of railway in operation.

Roads and Railways.—Good waggon roads intersect each other everywhere, and the Prince Edward Island branch of the Intercolonial Railway runs the whole length of the island, with branches to Georgetown, Charlottetown, and Cape Traverse. The Murray Harbour Branch Railway, under construction, will connect Charlottetown with Murray Harbour.

The chief towns are Charlottetown, the capital (12,080 in 1901), Summerside (2875), Georgetown (about 1060), Montague, Souris, Alberton, Kensington, and Tignish.

Ells, Geological Survey, 1882–83–84; Report of R. Chalmers, Geological Survey, 1894; Public Documents.—REV. G. SUTHERLAND. *Manual of History of Prince Edward Island*, 1861.—D. CAMPBELL. *History of Prince Edward Island*, 1875. (W. J. W.)

Prince of Wales Island, the official name of the island commonly called Penang by Europeans, and Pûlau Pînang (*i.e.*, Areca Nut Island) by the Malays, situated in 5° 24′ N. and 100° 21′ E., and distant about 2½ miles from the west coast of the Malay Peninsula. The island is about 15½ miles long by 10½

miles wide at its broadest point. Its area is something over 107 square miles. The town, which is built on a promontory at a point nearest to the mainland, is by no means imposing. It is largely occupied by Chinese and Tamils, though the Malays are also well represented. Behind the town, Penang Hill rises to a height of some 2700 feet, and upon it are built several Government and private bungalows, which are much used both as health and pleasure resorts. The town possesses a fine European club, a racecourse, and good golf-links. Cocoanuts are grown in considerable quantities along the seashore, and rice is cultivated at Bâlek Pûlau and in parts of the interior of the island, but for the rest the jungle still spreads over wide areas. Penang forms, after Singapore, the most important settlement in the Crown colony of the Straits. It has an excellent harbour, and is much used by shipping; but in this respect it has suffered from its proximity to the more important port of Singapore. There are a Church of England and a Roman Catholic church in the town, and a training college under the Roman Catholic missionaries of the Société des Missions Étrangères at Pûlau Tîkus, a few miles outside the town.

History.—Penang was founded on 17th July 1786, having been ceded to the East India Company by the Sultan of Kĕdah in 1785 by virtue of an agreement entered into by him with Captain Light, in consideration of the payment of a sum of $10,000 for a period of eight years. In 1791 the subsidy was changed to $6000, to be paid annually in perpetuity; but some years later this was raised to $10,000, which amount is still annually paid to the Sultan of Kĕdah. This final addition was made when the strip of mainland now called Province Wellesley was purchased by the East India Company for $2000 in 1798. At the time of the cession Penang was almost uninhabited. In 1796 it was made a penal settlement, and 700 convicts were transferred thither from the Andaman Islands. In 1805 Penang was made a separate presidency, ranking with Bombay and Madras; and when in 1826 Singapore and Malacca were incorporated with it, Penang continued to be the seat of Government. In 1829 Penang was reduced from the rank of a presidency, and eight years later the town of Singapore was made the capital of the Settlements. In 1867 the Straits Settlements were created a Crown colony, in which Penang was included. Since then it has been under the administrative control of a resident councillor, who is responsible to the Governor of the Straits. He is aided in his duties by officers of the Straits Civil Service.

Population.—The estimated population of Penang in 1898, exclusive of Province Wellesley, amounted to 154,850 souls. The population is divided into the following nationalities: Europeans, 1173; Eurasians, 1814; Chinese, 80,511; Malays, 44,790; Indians, 24,893; other nationalities, 1669. The number of births registered in Penang in 1898 numbered 1178 males and 1058 females, a total of 2236, giving a ratio of 14·44 per thousand of the population of the island. The number of deaths registered was 3364 males, 1142 females, a total of 4506, being a ratio of 29·10 per thousand of the population. From this it will be seen that in Penang, as in other parts of the Straits Settlements, the deaths annually far exceed the births, this being due to the disproportionate smallness of the female as compared with the male population. None the less the population of Penang yearly increases, owing to immigration from China and the mainland of India.

Shipping.—The number of ships which entered and left the port of Penang during 1898 was 5114, with an aggregate tonnage of 3,761,094. Of these, 4412 were British, with an aggregate tonnage of 2,847,301.

Finance and Trade.—The revenue of Penang, including that of Province Wellesley, amounted in 1898 to $1,653,767, of which $1,084,839 was derived from the revenue farms for the collection of import duties on opium, spirits, &c.; $102,909 from land revenue, $120,987 from stamps, and $65,000 from postal revenue. The expenditure for 1898 amounted to $1,211,267, of which $844,719 was spent on the administrative establishments, $103,028 on the upkeep of existing public works, $69,604 on the construction of works and buildings, and $87,780 on the construction of roads, streets, &c. The revenue in 1900 amounted to $1,736,130.

The imports in 1899 were valued at $69,078,371, the exports at $61,424,108, making the total value of the trade of the year up to $130,502,479. Of the imports in 1898 the value of $6,339,203 came from Great Britain, and $25,075,737 from British possessions. The exports to the United Kingdom were valued at $10,299,968, and those to British possessions at $10,920,735. The principal exports were pepper, tin, rice, and sugar; but all these things were brought from the mainland, none being produced on the island itself in any quantities.

See *Straits Settlements Blue Book containing Annual Reports for 1898*, Singapore, 1898. *Straits Directory for 1900*, Singapore.

H. CL.

Princes' Islands, the ancient *Demonesi*; Byzantine, *Papadonisia*; Turk, *Kizil Adalar*, or "Red Islands," from the ruddy colour of the rocks, a cluster of nine islands in the Sea of Marmora, which forms a kaza of the prefecture of Constantinople. Four of the islands are inhabited, and noted for the mildness and salubrity of their climate—Prinkipo (*Pityusa*), altitude 655 feet; Khalki (*Chalcitis*; Turk, *Heibeli*), altitude 445 feet; Prote (Turk, *Kinali*), altitude 375 feet; and Antigone (*Panormus*; Turk, *Burgaz Adasi*), altitude 500 feet. The others are Oxeia, a marble rock 300 feet high; Plate, Pyti, Antirobitho, and Neandro. The buildings on all the islands were injured by the earthquake of 1894, especially the naval college, and monastery of St George on Khalki, and the monastery of Christ on Prinkipo. Population about 10,000, of whom more than half are Greeks. On Prote were the monasteries to which Bardanes, Michael I. Rangabe, Romanus I. Lecapenus, and Romanus IV. Diogenes were banished.

Princeton, a city of Indiana, U.S.A., capital of Gibson county. It is at the intersection of the Evansville and Terre Haute and the Louisville, Evansville, and St Louis (Southern) Railways, in the south-western part of the state. Population (1890), 3076; (1900), 6041, of whom 198 were foreign-born and 628 negroes.

Princeton, a borough of Mercer county, New Jersey, U.S.A., on high ground between the Millstone river and Stony brook, at an altitude of 209 feet. It is on the Delaware and Raritan canal, and on a short branch from the main line of the Pennsylvania Railroad, between Philadelphia and New York. It is chiefly known as the seat of Princeton University (which see). Population (1890), 3422; (1900), 3899, of whom 508 were foreign-born and 899 negroes.

Princeton University, situated in Princeton, New Jersey, U.S.A., originally named The College of New Jersey. It was founded in 1746, in Elizabethtown, N.J., but was removed to Newark, N.J., and finally, in 1754–55, the first college building, Nassau Hall, was erected at Princeton. During the period before the American Revolution it graduated many men of distinction, among them Richard Stockton and Dr Benjamin Rush, who, with John Witherspoon, president of the College, were signers of the Declaration of Independence; James Madison, fourth president of the United States; twenty-two members of the Continental Congress, and nine members of the Convention which framed the United States Constitution. It has since maintained its place among the leading American colleges. In 1896, responding to the general movement towards advanced instruction and special research, it was incorporated as a university, although, unlike many American universities, it has no law school and no medical school. It is governed by a president and a self-perpetuating board of twenty-six trustees, and five other trustees elected by the alumni, and is independent of state or denominational control. There were, in 1901, 760 undergraduates in the academic or classical department, pursuing courses leading to the degree of Bachelor of Arts, and 477 undergraduates in the John C. Green School of Science, divided among the departments of electrical engineering, civil engineering, and general science. The graduate students, who constitute the university element proper, numbered 138. The higher degrees conferred are Master of Arts, Master of

Science, Doctor of Philosophy, Doctor of Science, and Bachelor of Divinity. There were 46 professors, 19 assistant professors, 40 instructors, assistants, and lecturers, and 16 fellows.

Pringsheim, Nathanael (1823–1894), German botanist, was born at Wziesko in Silesia, on 30th November 1823. He studied at the universities of Breslau, Leipzig, and Berlin successively. Though at one time intended for the medical profession, his tastes were always for pure science, and it was as doctor of philosophy that he graduated in 1848, with the thesis *De formâ et incremento stratorum crassiorum in plantarum cellulâ*. From that time onwards his life was devoted to botanical research, and he rapidly became a leader in the great botanical renaissance of the 19th century. Until Pringsheim was over fifty his work was entirely on the morphological side of the science, and in this direction his great triumphs were won; during the last twenty years of his life he turned his attention to physiological questions, but with less marked success. His contributions to scientific algology were of striking interest. Pringsheim was among the very first to demonstrate the occurrence of a sexual process in this class of plants, and he drew from his observations weighty conclusions as to the nature of sexuality. Together with the French investigators Thuret and Bornet, Pringsheim ranks as the founder of our scientific knowledge of the Algæ. Among his researches in this field may be mentioned those on *Vaucheria*, 1855, the Œdogoniaceæ, 1855–58, the Coleochætcæ, 1860, *Hydrodictyon*, 1861, and *Pandorina*, 1869; the last-mentioned memoir bore the title *Beobachtungen über die Paarung der Zoosporen*. This was a discovery of fundamental importance; the conjugation of zoospores was regarded by Pringsheim, with good reason, as the primitive form of sexual reproduction. A work on the course of morphological differentiation in the Sphacelariaceæ (1873), a family of marine Algæ, is of great interest, inasmuch as it treats of evolutionary questions; the author's point of view is that of Naegeli rather than Darwin. Closely connected with Pringsheim's algological work was his long-continued investigation of the Saprolegniaceæ, a family of algoid Fungi, some of which have become notorious as the causes of disease in fish. Pringsheim's work was by no means limited to Thallophytes; among his contributions to our knowledge of the higher plants, his exhaustive monograph on the curious genus of Water-Ferns, *Savinia*, deserves special mention. His career as a morphologist culminated in 1876 with the publication of a memoir on the alternation of generations in Thallophytes and Mosses; his theory will always hold its own as a brilliant attempt to solve the greatest problem of morphological botany. From 1874 to the close of his life Pringsheim's activity was chiefly directed to physiological questions: he published, in a long series of memoirs, a theory of the carbon-assimilation of green plants, the central point of which is the conception of the chlorophyll-pigment as a screen, with the main function of protecting the protoplasm from light-rays which would neutralize its assimilative activity by stimulating too active respiration. This view, though it no doubt contains an element of truth, has not been accepted as offering an adequate explanation of the phenomena. Pringsheim founded in 1858, and edited till his death, the classical *Jahrbuch für wissenschaftliche Botanik*, which still bears his name. He was also founder, in 1882, and first president, of the German Botanical Society. His work was for the most part carried on in his private laboratory in Berlin; he had little taste for professorial duties, and only held a teaching post of importance for four years, 1864–68, when he was professor at Jena. In early life he was a keen politician on the Liberal side, and even took part in the street fighting in Berlin during the "Annus Mirabilis." That adventure, however, appears to have finally extinguished his active interest in politics. He died in Berlin on the 6th of October 1894.

A fuller account of Pringsheim's career will be found in *Nature*, vol. li., 1895, and in the *Berichte der deutschen botanischen Gesellschaft*, vol. xiii., 1895. The latter is by his friend and colleague, Ferdinand Cohn. (D. H. S.)

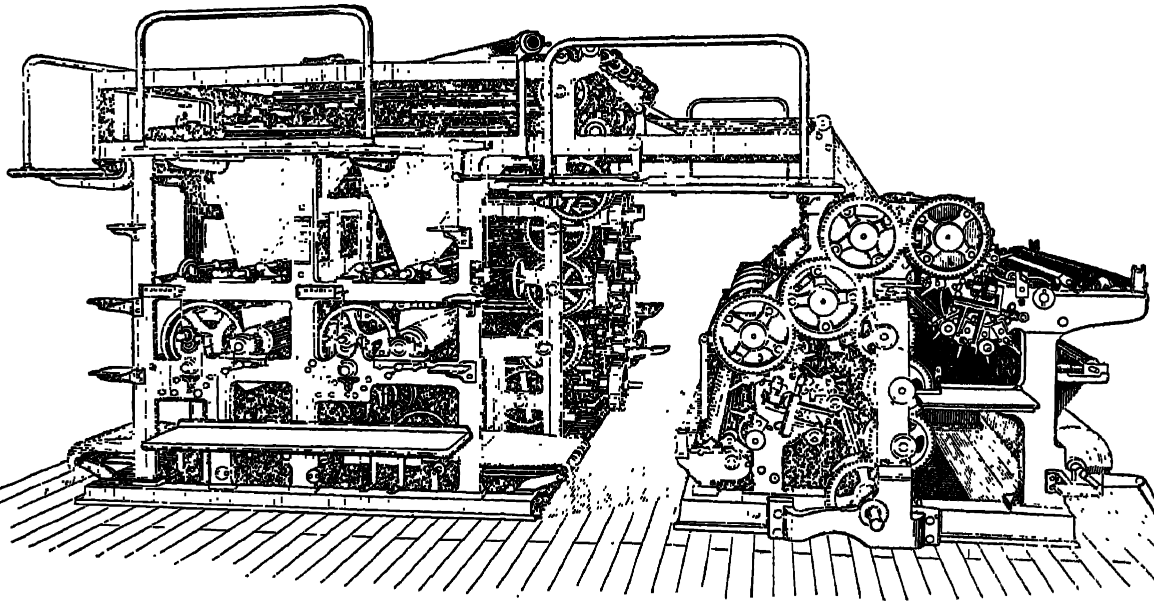
Printing, Book: See Book Printing.

Printing Presses.—Improvements in newspaper printing machinery are now sought in the direction of greater compactness and simplicity. The Goss Rotary of Chicago, also known as the straight-line machine, from that peculiarity in its construction, is an illustration of this tendency. The larger part of this machine is in four sections, apparently exactly alike, each section at times independent of other sections. Four webs of paper, four impression and four plate cylinders are in a vertical line. In the process of printing from four rolls, the sheets from each roll move in a horizontal line until they near the end of the machine, in which position they are folded, conjoined, and thrown out ready for delivery. As each section is independent, one section only, which prints 4 pages, can be used, and the other sections thrown out of gear. When combined, two sections will print 8 pages, three sections 12, and four sections 16 pages.

As rotary machines for the rapid printing of newspapers in two or more colours always require for each colour a separate ink-fountain and rollers, and usually a separate plate cylinder and impression cylinder, their production is not so great as the machine of same size made for black ink only. A successful form of colour machine, made by Marinoni, of Paris, is used for printing in six colours more than 1,000,000 copies on each edition of the weekly illustrated supplement of *Le Petit Journal*. Colour machines of American design are used by a few papers of New York for their Sunday and holiday editions. A machine recently made in that city is intended to produce 48,000 papers, cut and folded, with an inset sheet, and a cover in four colours. All the colour presses now made register with perfect accuracy, but much has yet to be learned about the making and management of the paper and the inks adapted to colour work. Rotary machines printing from a continuous roll have their limitations. They are constructed usually so that they can print one size only of paper, and that size must be in length the exact circumference of the impression cylinder.

Machines for printing books and jobs are of simpler construction and of slower speed. The *drum cylinder*, so called from the large size of the cylinder, makes one revolution for each impression; but as the width of the bed containing the type is about one-third the circumference of the cylinder, the actual printing of the sheet takes up but one-third of the time the cylinder is rotating. During two-thirds of its rotation no printing can be done. On the smaller sizes of drum cylinder, 1800 impressions an hour can be had; on the larger, about 1000. The *two-revolution cylinder*, which makes two revolutions to each impression, and can be made to produce 1500 or more impressions on a large sheet in one hour, is preferred for its compactness and its somewhat greater speed. The *stop-cylinder* (invented by Dutartre, of France, in 1852) is a little inferior to the two-revolution cylinder in performance, but it has marked merit in greater strength and accuracy of movement, and is largely used for the printing of woodcuts and the best colour work. In this machine the cylinder stops after every impression and allows the feeder to place properly the sheet to be

printed. The bed containing the type is moved to and from impression by steady wheel motion. The ink is distributed upon a table as well as by vibrating rollers. The *Perfecting Press* of two cylinders prints from a flat type bed the outer and inner side of the same sheet by the same operation. It is a form of cylinder machine once largely used abroad, but is not approved in the United States, and is declining in favour in France. Its product is greater than that of the simple cylinder, but not more than that of two single cylinders, nor is it so easily managed. The *Rotary Art Press* (first made by R. Hoe & Co. for the printing of the illustrated formes



Quadruple Perfecting Printing Machine and Folder.

of the *Century Magazine*) is simpler and more manageable. Sixty-four electrotyped plates, curved and attached to a cylinder about 30 inches in diameter, are inked by 16 rollers. Impression is made against a cylinder of similar size which revolves at the same rate of speed. The sheets are fed by hand. Unlike all other hand-fed cylinders, this machine has no lost motion, for printing is continuous. Although it does four times the work of the stop-cylinder, the rotation of the cylinder is no faster, and the quality of the press work is really superior. For printing the plain type pages and advertising pages of this magazine a simpler form of web press is used, which is not so rapid as the web press of newspapers; but it performs more operations and does more accurate work. At every revolution it puts on the delivery-table 64 pages in exact register, truly cut, folded, and ready for the binder. Small cylinder machines are also made for printing cards, numbered railway tickets, pamphlets, stock and market reports, proofs for proof-readers, matrixes for stereotype plates, and for aluminium plates to be printed by lithographic process. Improvements in cylinders for book work have been made by several European mechanicians. At the Paris Exposition of 1900 Marinoni exhibited a perfecting cylinder which printed at one revolution at a rapid rate two colours on either side of the sheet. Alauzet and Voirin, of Paris, Rochstrop and Schneider-Nachf, of Dresden, König and Bauer, of Oberzell, and Schelter and Giesecke are makers of approved book and job printing machines.

Methods of printing have been as greatly changed as the styles of presses. Before 1870 nearly all the books and newspapers made in the United States were printed on damped paper. For the printing of types, damping was of advantage in aiding the quicker production of bold and black impressions, but for the printing of the finest engravings, dry paper of smooth surface was needed to show the delicacy of the finer lines. To attain this desired smoothness, paper-makers extended the application of calendering rollers for the quality now known as super-calendered paper, which is still largely used for the printing of ordinary illustrations. It is not possible, however, to give by calendering to the fibres of paper the smoothness of surface needed for the finest engravings. To produce perfect smoothness, the web of paper must be covered with a thin coat of whiting, which closes up all the pits in the fibre, and after calendering leaves it with a surface as smooth as polished metal. Paper so coated, when properly printed, will show a velvety black in the shadows of a cut and a paleness of grey in sky tints unattainable on pure paper fibre. The development in 1875 of photo-engraving by the Meisenbach process brought with it finer engraving with very shallow counters, and compelled a greater use of coated paper, which had to be printed dry. In 1880 the new process was so greatly improved that the so-called half-tone engravings began to supplant woodcuts in the magazines. As some of these half-tones were made behind screens of two hundred or more lines to the inch, the counters were unavoidably shallow, and printable only on the smoothest coated paper. Damping of paper was generally abandoned, not only for coated but for ordinary paper. This, in turn, compelled new methods of press-work. Woollen blankets and indiarubber impression-resists were supplanted by hard cardboard, which, as it pressed upon the face only of the cut, did not thicken its hair-lines. Much more time had to be given by the pressman to overlays and the exact graduation of impression for different tints on every illustration. Although the new method of hard-surface impression improved the appearance of the illustrations, it was wearing to the types, making them relatively deficient in boldness and blackness. The old-time boldness and blackness of type-printing have been appreciably sacrificed for the preservation of the higher delicacy of engraving.

All the old processes of stereotyping in plaster, or in clay, or in paper, were ineffective in book-printing, in that they could not fairly reproduce the fine work of a woodcut or an actinic plate. The more recently developed art of electrotyping is now used by all book printers for

types as well as for cuts, and even daily newspapers have to use it for issues containing illustrations of high merit. As first practised, the battery required about twelve hours for the making of the shell for an electrotype plate, but now, by the aid of the dynamo-electric machine, a fair shell can be produced in one or two hours. (See also TYPE-SETTING MACHINES, ENGRAVING, ELECTRO-METALLURGY, NEWSPAPERS, BOOK PRINTING.) (T. L. DE V.)

Prishtina, PRICHTINA, or PRISTINA, the chief town of a sanjak in the vilayet of Kossovo, European Turkey, situated on the Sitnítza, an affluent of the Ibar, 3 miles east of the station on the Salonica–Metrovitza Railway, 60 miles north-east of Prizren. It is the seat of a governor-general and of a general of division, and possesses seventeen mosques, a military hospital, and a higher class school. The trade is considerable, the imports including sugar, coffee, hardware, iron and steel, &c., and the exports chrome, wheat, maize, barley, skins, and wine. The Prishtina valley was the scene of the final combat between the Turks and Servians, which led to the establishment of the Ottoman Empire in the Balkan Peninsula. Population, 21,000.

Prison Discipline.—Great changes were introduced into the methods of enforcing penal discipline during the latter decades of the 19th century, and there has been a steady progress towards milder and more enlightened methods of prison treatment. Some new and remarkable experiments have been tried, especially beyond the Atlantic, and everywhere much attention has been paid to penal problems. This has shown itself abroad by the almost universal adoption—at least in theory—of principles hitherto accepted as paramount in Great Britain. The prison cell, which in effect typifies the modern system, has been long an established British institution. The separation, more or less strict and prolonged, of prison inmates has been esteemed an essential part of penal treatment, and of late years all civilized nations without exception have built or started building new prisons to carry out this form of treatment. France has shown much progress in this direction. Great additions have been made to La Santé in Paris, and an entirely new building on the very latest plan has been constructed at Fresnes-lès-Rungis to replace the once famous but somewhat obsolete gaol of Mazas and other prisons of the Seine. Germany has taken up the question of penitentiary reform, and new establishments on the cellular system have been erected; while Austria, Russia, Spain, Portugal, Holland, Denmark, Norway and Sweden, Switzerland, even Japan, all have been busy in providing separate cells for their prisoners. In Italy a comprehensive scheme has been drawn up, so that cellular imprisonment may become a general rule. In Belgium, where penal administration has received the closest attention for a number of years, the *régime* of cellular imprisonment has been long carried to its farthest limits, and solitary confinement ranging over ten years, and in some cases much more, has been strictly enforced. Of late years, however, a new school has arisen in Belgium which dissents from the hitherto accepted principle, and expresses strong doubts of the wisdom or efficacy of prolonged cellular confinement. In England, moreover, which if not the first to adopt separation in principle, certainly gave the largest effect to it in practice, continuous cellular confinement for short terms is ceasing to be the universal inevitable rule. A growing dislike to it has been manifested by both experts and philanthropists; the terms for which it could be inflicted have been constantly diminished; and although it is still retained in cases of penal servitude for the first six months, it was in 1899 practically abandoned for lesser sentences, and all prisoners after the first month work together in association under surveillance. This is neither more nor less than the adoption of the old-fashioned Auburn system, which in old days held the ground against the solitary system of Pennsylvania. The bias of modern practice, in short, is towards milder methods, not only in prison treatment, but in those anticipatory processes which if successful may render imprisonment unnecessary.

It has been well said that criminals are such by accident or inclination, and that under a perfect system of government they should be spared the one and cured of the other. Consistent attempts have been made to follow out this principle. When prevention ends reformation begins. The first includes child rescue, the general raising of the moral standard by education; the second, painstaking efforts to improve the character of all subjected to the chastening influences of imprisonment. Very beneficial results have been obtained by the care devoted to juveniles, who from inherited disposition, the neglect of parents, vicious surroundings, evil advice and example, might lapse into misconduct. The recruitment of the vast army of crime is cut off at its source. Great forbearance is shown to the less hardened offenders for whom there is reasonable hope of recovery. The law is loth to appeal at once to repressive measures, and does not necessarily apply the *ultima ratio* of the gaol. Several important Acts have been passed, having for their object the more merciful treatment of first or venial offenders. The punishment of such as are charged with anything less than the most heinous crimes may be held over pending good behaviour. The Probation of First Offenders Act discharges provisionally and practically pardons those who have not committed any previous offence, and some 5000 of these have annually escaped imprisonment since 1893. Moreover, the Summary Jurisdiction Act, 1879, by affording time for the payment of fines, keeps numbers of offenders out of gaol. Quite 46,000 were thus suffered to remain at large and seek funds for the discharge of their fines during 1899. A careful examination of the sentences now inflicted will show that they have steadily decreased in severity; for those who are still condemned to pass the gaol gates considerable modifications in penal treatment have been devised. Continuous cellular seclusion is no longer the rule. The older harsher forms of penal labour have been abolished; the crank which ground only air has all but disappeared, and if the treadwheel is still retained, it is made to fulfil the useful purpose of water-raising or grinding wheat. The 39 treadwheels and 29 cranks still in operation in 1895 had dwindled down in 1901 to 13 and 5 respectively, and they also will shortly be abolished. Attention is as far as possible concentrated on industrial labour, and great pains are employed to instruct prisoners in handicrafts and the manufacture of useful articles, which can be carried on as wage-earning trades in freedom. In deference to popular demand, great additions were made to prison dietaries, and these, if not actually excessive, compare favourably with the food issued in workhouses and with the general allowance of the poorer classes. The privilege of correspondence with friends outside and of receiving visits has been enlarged; additions have been made to prison libraries, which now contain works of fiction and other entertaining literature; the rule of silence during hours of association is relaxed for certain classes of prisoners. The use of tobacco, which is permitted in many prisons on the Continent and in the United States, but has been prohibited in the United Kingdom, is recommended by some reformers, who have also urged that lectures and other entertainments should be provided, and that, following

the example of some American prisons, the forbidding character of the gaol as a place of durance and punishment should largely be made to disappear.

So far these more extravagant views have not been generally accepted. But the pendulum has always oscillated between severity and mildness, and the recent movement has been in the latter direction. The new departure dates from a report of a departmental committee in 1895, which had been appointed by Mr Asquith to review the existing system of treatment of prisoners, and suggest changes in prison administration. The inquiry admitted that the centralization of authority in 1878 had been a complete success, as shown by increased economy in working and by the enforcement of uniformity in prison discipline. The committee was, however, dissatisfied with the moral results achieved, and thought that more attention should be paid to reformatory processes. They believed that "few inmates left prison better than they came in." Recommittals were frequent, and "recidivism"—or repeated reconviction of the same individual—was increasing. To make imprisonment more deterrent on the one hand to the habitual criminal class, and on the other hand more improving to the hopeful and less hardened offenders, was the aim of any good system, and the committee's recommendations dealt mainly with the latter aspect. They were accepted by Mr Asquith, then Home Secretary, as indicating the line which reform should take. The more academic and somewhat visionary theories of increasing the staff of chaplains and schoolmasters, and the calling in of outside exhortation, whereby each individual might be dealt with personally, have not borne much fruit. But the more minute classification of prisoners has worked well. Not only are the convicted and unconvicted kept apart, but the juvenile and first offenders are strictly separated from habitual criminals. The principle of the "star class," so successfully tried since 1879 in the convict prisons, has been extended to the local prisons; a prisoner never previously convicted is designated as a "star," and absolutely segregated from his fellows at chapel, labour, exercise, and quarters occupied. The salutary results of this system have been proved by prison statistics. Between 1879 and 1899, 2435 convicts were placed in the "star" class, of whom no more than 1·2 per cent. have been sent back to penal servitude under fresh sentences, and only 1·3 per cent. have forfeited their tickets of leave. The same results are shown in a lesser degree in the local prisons; in the four years 1897–1900, out of 29,195 males and 5823 females placed in the "star" class, 7·1 per cent. only of the former and 11·7 of the latter have been relegated to prison. Great emphasis was laid by the committee upon the development of agencies for the assistance and rehabilitation of the released, and the excellent work already done by private societies for the aid of discharged prisoners has been systematized and their functions enlarged. The help thus given is of the most useful kind, and tends to encourage good resolutions formed in gaol by keeping the weak or friendless, on their first reappearance in public, away from the evil influences of former associates. Reformatory institutions have also been opened to others than juveniles. One rule which restricted admission to youths below 16 has been modified to take in adults at 16 and retain them till they were 21, and the creation of a large penal reformatory for all such was mooted by the committee of 1895 and adopted in 1901, when a "juvenile-adult reformatory" was opened at Borstal, near Rochester, by the conversion of a part of the existing convict prison. It has been shown by undoubted figures that there is a "criminal age," a period ranging between 16 and 30, when more than 50 per cent. of the total indictable offences are committed; and it is held by expert authority that much might be done in this way to prevent lapses into crime at the most susceptible period. The principle has found practical illustration in the United States, where the reformatory system, as applied to adults and to full grown men (not children and juveniles), has reached an extraordinary development. Elmira, in the state of New York, and Concord, in Massachusetts, are typical establishments, whose methods deserve to be detailed. Their principal aim is to substitute complete moral regeneration for punishment. There is supposed to be nothing vindictive in the treatment. They are prisons in reality, but not in name, and those committed to them are called inmates, not prisoners. The offender is to be pitied, not punished, and it is held to be the duty of the public as well as its best safeguard to make another man of him. With this object in view he is handed over to be dealt with under an elaborate system of physical, intellectual, and industrial training, with no specific sentence, but for such period, with certain limits, as may be found necessary by the agent who is to carry out the desired change. These processes depend upon gymnastic and military exercises, upon a wide curriculum of instruction, and upon apprenticeship in some handicraft or technical trade. Much importance is attached to physical agencies; the Turkish bath is in constant use, and the frame is strengthened and its normal healthful functions highly developed. At Elmira there is a newspaper, written, edited, and printed by the inmates, and prison journalism of this kind is not at all uncommon in the States. The inmates are also formed into battalions of infantry, carefully drilled to manœuvre and march to the strains of an excellent band. Admission to these state reformatories is by the order of a high tribunal, the ages of offenders selected ranging between 15 and 35. The crimes committed are such as robberies, forgeries, manslaughter, embezzlement, receiving, and others of lighter character. The course of treatment is carefully prescribed, and each inmate passes through progressive stages, promotion from grade to grade being dependent upon application and good conduct. The discipline is more severe than the system would imply, and is enforced by ingenious penalties and the use of the "paddle" or stick. Considerable results are claimed for the treatment, but they are based upon presumption rather than upon positive fact, for the supervision that follows "parole" or conditional discharge covers no more than one year, and is chiefly exercised through relations and employers. According to the reports received, the Elmira pupils who do well amount to 78 per cent. of the total. No doubt they have much encouragement, not only in the acquisition gratis of a high-class education—which is denied to those who have never offended—but in the care bestowed upon them on release. No inmate leaves Elmira until a situation has been found for him, adapted to his abilities and recent training. It is not easy to strike the balance between excessive care bestowed on unworthy objects and the value to the community in the reclamation of delinquents by such extravagant means. More positive and more tangible results are hoped for from the less ambitious methods to be pursued at Borstal. Reliance will be placed upon a strict discipline and useful instruction in wage-earning trades, while all cases will be carefully watched on discharge by an association of kindly workers, ever ready to give advice and assistance to the well-intentioned. The character and scale of these may in a measure be judged by the following particulars concerning the former:—

The Elmira Reformatory, the buildings of which are large and thoroughly equipped, was opened in 1876. Only male felons who have not hitherto been convicted of felony are sentenced to the reformatory. They are com-

mitted there for a period not to exceed the maximum term provided by law for their particular offence had they been sentenced to a state prison instead. This indeterminate sentence, as well as the process of training and reformation in place of the ordinary punishment, distinguishes the reformatory from an ordinary prison. (Besides those sentenced to an indefinite term, there are a few—about one-tenth of the total number—sentenced to a definite period, but the board of managers has strongly recommended that these "definites" should no longer be received.)

On admission a man is assigned to the intermediate of the three grades in the institution, and from this grade he is promoted or degraded according to his conduct. He is at once set to learn a trade, if he does not already possess one, and he works at this half the day, the other half being spent in work connected with the institution. Three evenings each week every inmate attends school. After six perfect months in the medium grade he is eligible for promotion to the highest grade, and after six perfect months in this grade he may be paroled, at the discretion of the management, on condition that he has employment awaiting him and that he report to the management every month for six months. At the end of this third six months he may receive an absolute discharge. Certain privileges, especially in regard to food, dress, and letters, depend on the grade of the inmate. The men receive definite wages, 55 cents per day in the highest grade and 45 cents in the others. Out of their wages they must pay for their board, clothes (apart from the outfit given them on entrance), and also pay the fines imposed upon them for offences in demeanour and failures in trade or school. A monthly account is kept with each man, and he cannot be promoted unless he has a credit balance, nor paroled until he has saved enough to take him to his future place of employment. The discipline and daily life of the institution are largely of a military character. The men are organized into a regiment, are thoroughly drilled, and dress parade is held daily. Flogging has been abolished.

The number in the institution on the 30th September 1901 was 1276, the average number during the preceding twelve months being 1338. The total net cost of maintenance for the year was $205,021, or an average cost of 42 cents per inmate per day. Although no persons are sentenced to the reformatory who have previously been convicted of a felony, still a large proportion have been previously imprisoned for less serious offences. Of the 1276 inmates above mentioned, 559 had previously been confined in gaols, reformatory schools, penitentiaries, &c.

The total number of inmates received from the opening of the institution to the end of September 1901 was 11,046, of whom 10,540 had been sentenced for indefinite terms. The average age of inmates has been 21 years. Of the 10,540 "indefinites" received, 7010 have been released on parole. Of this number 508 were returned to the institution, of whom 257 were ultimately re-paroled, 209 were otherwise discharged (through expiration of maximum sentence, transfer to other prisons, &c.) or died, and 42 were still at the reformatory. Of the remaining 3530 "indefinites" not paroled the following statistics are given: absolutely released without parole, 27; maximum sentences expired, 935; pardoned, 33; escaped, 29; died, 199; transferred to other prisons, state hospitals, &c., 1137; now remaining in the institution, 1170.

It has been often debated whether or not prison discipline reacts upon the criminality of a country; whether, in other words, severity of treatment deters, while milder methods encourage the wrong-doers to despise the penalties imposed by the law. Evidence for and against the theory is drawn from the whole civilized world. In France crime increases by leaps and bounds (especially in the most serious forms—murder, parricide, poisoning), yet in French prisons of late years the rule of strict cellular confinement has obtained, while banishment to the uttermost ends of the earth is in force as a grievous punishment for a people so attached to the soil. There is the same very marked increase in the United States, in spite of the reformatory systems described. On the other hand, in Belgium a steady diminution is to be noted in the numbers committed to prisons in which that most irksome of all restraints, unbroken solitude for years, is inflicted. In Great Britain the whole tendency of legislation and administration has been towards leniency, and a steady decrease in crime has been long in progress—a fact combated by some critics, but based upon indisputable official figures. Taking England and Wales for illustration, although the same results are still more marked in Scotland and Ireland during the period 1860–1900, the total number of penal servitude sentences per annum has decreased from 2589 in 1859 to 728 in 1900, in spite of the growth of the population. The readiest method of contrast is by comparing the number of persons sentenced per 100,000 of the general population, and this works out at 13·4 in 1859, with successive reductions to 9·1 in 1869, 6·6 in 1879, 3·3 in 1889, and 2·3 in 1900. It has been urged that this diminution means no more than a reluctance in the various jurisdictions to impose the heaviest penalties, even for serious offences, but in that case a proportionate increase would be shown in the population of local prisons, in which sentences less than penal servitude are carried out. Yet taking these "local" prisons from 1878, the year in which they were brought under direct Government control, the same strongly marked decrease is (with some few fluctuations) to be observed. Thus at the date of the change in administration the total number of convicted prisoners in custody in the gaols was 20,833; this fell by 1000 within a year, and the move has since been generally downwards. In 1888 the total had sunk to 14,536, in 1892 to 12,663; in 1899 it had risen slightly to 14,957, and in 1901 it had again decreased to 14,739. The decrease may be better appreciated by taking the figures relatively with population. Thus for the quinquennial period ending 31st March 1885 the yearly average imprisoned for indictable offences was 37·8 per 100,000 of the population in England and Wales; for the next five years it was 32·7; the next, 28·0; for the five years ending 1900 it had fallen to 25·0, and for 1901 it was no more than 22. Consideration must be had to the character of the offences for which imprisonment was meted out. The more serious of those dealt with by indictment has continuously decreased; the increase has followed summary convictions for minor offences, many of which are no more than infractions of police rules, such as the order to muzzle dogs, or to prevent annoyance by the improper use of bicycles or motor-cars.

Satisfactory as the facts on the whole appear with regard to the decrease of the numbers incarcerated in England, it cannot be concluded that crime is distinctly on the wane. There may be fewer heinous offences compared to population, but they are more persistently repeated by the same persons. The gravest feature in modern penology is the vitality of "recidivism"—to adopt the term of French origin which expresses the persistent, reiterated lapses of the same individual into wrong-doing. Rather more than half the whole number of serious crimes are the work of the "habituals." A few figures will show this most clearly. In the official year ending 31st March 1899 there were in

Recidivism.

all 113,182 males and 45,288 females committed to prison on conviction of crimes. Rather more than half the males and nearly two-thirds of the females had been previously convicted, not merely once, but twice, thrice, up to twenty times and more. Some of the figures are most extraordinary. There were 19,313 males and 6062 females with one previous conviction; with four previous convictions the numbers were 3891 males and 2013 females; from six to ten times, 8558 males and 5269 females; from eleven to twenty times, 6079 and 5393; above twenty times, 4182 and 6639. It will be noted that by far the largest proportion of recidivists were females, but men and women alike offered themselves perpetually for reimprisonment. We have thus a grand army constantly on the march through prison, subjected all of them to the various processes known to and tried by penal administration, and yet undeterred by the treatment. Nothing has availed to check or cure them—neither the most irksome restraints on the one hand, nor the most philanthropic efforts of moral and educational persuasion on the other. It is the criminal residuum, the essence of the criminality of a country, a contingent ever at war with society, persistently defying the law and refusing to abide by the rules of conduct accepted by others. The State retaliates as best it can; it takes the criminal red-handed, punishes him, secludes him, exhorts, cautions, assists him when he is once more free, but it still largely fails to transform him into an honest, law-abiding citizen. Call them what we will—born criminals in the phraseology of the Lombroso school, the product of an imperfect social system, criminals by predestination, uncontrollable tendency, mere accident or neglect—criminals a large proportion will continue to be to the end of the chapter. Their path is chosen and will be trodden while they live; they are a terror and a danger to society while at large, incorrigible while in custody, intractable—at least to any methods hitherto applied. This failure to cope with habitual crime has led to the invention of the "indefinite sentence," adopted beyond the Atlantic. It means a system of indeterminate imprisonment, under which the hardened offender would be kept from doing more harm until there was reasonable hope that he was weaned from his evil ways. But the scheme bristles with difficulties. The reluctance of judges to sentence even the most abandoned offenders to nearly interminable periods of detention has to be overcome.

The progress made in prison treatment will be best realized by a brief survey of penal institutions in the principal countries of the world. It will be convenient to take them alphabetically.

1. *Austria-Hungary.*—The *régime* of cellular confinement has not been universally adopted; only six prisons are built on that principle, and no more than 15 per cent. of the whole number of prisoners can be subjected to the system. Cellular separation is not inflicted for long periods, the minimum being six months and the maximum three years. The bulk of the prisoners live and labour in common. A great feature has been the execution of public works by prisoners in a state of semi-liberty beyond prison walls—the practical adoption of the so-called "Irish" or intermediate prison—and good results are seen in road-making and the improvement of river-beds. The reformatory at Aszod was built by convict labour, and also the fine prison of Marburg on the Drave. New prisons have been constructed at Pilsen, Prague, Stanislau, Budapest, Streu, and Wiener Neudorf, all on the best lines and with liberal expenditure, but older establishments are still to be found—convents, monasteries, and castles—being appropriated to service. A number of societies (35) exist to aid discharged prisoners. Recidivism is very constant, and the existing discipline does not sufficiently restrain the habitual criminals, as is shown by a serious *émeute* in the prison of Garsten in 1890. In the new prison at Rozsahegy, in Hungary, the inmates are chiefly engaged in agriculture.

2. *Belgium.*—This country has spared no pains and no money in carrying out penal processes, and the Belgian prisons are examples of the cellular system prolonged to the utmost limits of human endurance. There is a minimum of ten years, but the individual may elect to continue in separation, or be transferred to partial association. Many, it is said, still prefer the living death of the cell, and cases are known of prisoners who have passed fifteen, twenty, even twenty-three years in unbroken solitude. Great results are claimed for the system, and judged by the test of diminishing crime it appears to have succeeded, though it fails to prepare those who endure it for the struggles of everyday life. The treatment is especially recommended for recidivists, whom no doubt it removes more or less entirely from the theatre of crime. A new school of Belgian criminologists has been headed by M. Prins, the chief of the department, who has protested that any hope that the vicious, hardened offender after a long detention, "surrounded with every attention, soaked with good counsel, will leave his cell regenerated," is a Utopian dream. Some of the Belgian prisons are magnificent edifices; that of St Gilles in Brussels is of imposing architecture, and was built regardless of cost; modern establishments, such as those of Louvain, Merxplas, and the new quarter at Ghent, are built on an excellent plan, and all of them are cellular.

3. *British Empire.*—The principle of cellular separation was accepted as far back as 1836, and the model prison of Pentonville, opened in 1842, has since been copied throughout the civilized world. The cellular system has been adopted in all British colonies with various modifications, and prisons built on modern principles are to be found in Canada, Australia, New Zealand, and the Cape of Good Hope. India retains association as the system most suitable for its criminal classes, with other methods generally abandoned by Great Britain, such as the employment of well-conducted prisoners as auxiliaries in prison discipline and service. Deportation is still the penalty for the worst offences, and is carried out on a large scale and with satisfactory results in the Andaman Islands. In Egypt since the establishment of British control a very marked change has been introduced in prison affairs under the active and enlightened initiative of Dr Crookshank Pasha. The great public works prison of Tourah, near Cairo, employs a large number of convicts in the neighbouring quarries; parties of them accompanied the Anglo-Egyptian advance into the Sudan, and assisted greatly in railway extension, in loading and unloading stores, and other "fatigue" duties. Although the cellular system has made no great progress, the new and improved prisons at Alexandria, Gizeh, Assiut, and elsewhere are well and carefully managed.

4. *Denmark.*—In Denmark all convicted prisoners pass through several stages, from cellular treatment to the intermediate prison and conditional liberty. Two new prisons on the latest model have been erected at Copenhagen, one for males and the other for females. The smaller gaols for short times are mostly on the cellular plan.

5. *France.*—France has devoted very considerable attention to prison matters, and is now practising the two extremes of treatment, the strict cellular isolation of the Belgian system, and the penal exile or transportation which was long the English rule. The conversion of her numerous provincial prisons into cellular has not yet been possible, but a splendid prison for Paris, replacing the obsolete Mazas, St Pélagie, and La Roquette, has been built in the suburbs at Fresnes-lès-Rungis, near Bercy, on the Seine. It contains 1780 cells, and embodies all the latest ideas and appliances in prison construction, douche baths, electric light, iron bedsteads. The cells have varnished walls, perfect ventilation, and the best hygienic services. There is also a quarter for 400 prisoners in association, so that the total prison population will exceed 2000. The old prison of La Santé in Paris has also been transformed into a cellular prison, with the same liberal provision of modern improvements, and contains now 1150 cells. Much is hoped from these new methods both in deterrence and reformation, but recidivism is steadily on the increase in France, and has resisted all treatment. The law of "relegation," which prescribed that all habitual offenders should be sent back to the penal colonies, has not worked well. The results of deportation generally have been most unsatisfactory. In Cayenne, in French Guiana, which has a climate deadly alike to convicts and their guardians, the hoped-for colonial development has proved disappointing. Even in New Caledonia, to which upwards of 30,000 convicts have been sent, and where the conditions are far more favourable to colonization, since it possesses a fruitful soil, a splendid climate, and unlimited mineral wealth, little substantial advance has been made. Some miles of road open for wheel traffic, a few thousand acres brought under cultivation, and one or two mediocre public buildings in the capital, Noumea, sum up the achievements of this vast amount of labour provided gratis for the improvement of the colony. France is encountering all the objections that led to the abandonment of deportation by Great Britain. It has been inordinately costly, unequal in incidence, and barren of substantial results in the rehabilitation of the criminal exiles, who, as free immigration has increased, have become more and more distasteful to their fellow colonists. The climax will come when the free settlers outnumber the liberated, and the colony refuses to be further contaminated.

6. *Germany.*—The unified German empire has not as yet adopted one system of prison treatment, and its various component kingdoms still retain independence in views and practice.

Baden has a well-known cellular prison at Bruchsal, but separation is not imposed for more than four years, and associated labour is carried out in another quarter of the prison.

Bavaria has four cellular prisons, the chief being at Munich and Nuremberg, but the collective system also obtains.

Prussia having declared for the cellular system and constructed the well-known Moabit prison in Berlin, those of Ratibor in Silesia, of Herford in Westphalia, and of Graudenz, Breslau, Werden, and Cologne have been added since. Frankfort has a good prison on the Pentonville (London) plan; so has Hamburg; and new buildings have been erected at Wohlau, Siegburg, Breslau, and Munster. Separate cells in Prussia had increased in 1896 from 3247 to 6573. The cellular *régime* is applicable to prisoners between 18 and 30, and to first offenders of 50 years of age, the term being fixed by the governor of the gaol, but never exceeding three years.

Saxony established a penitentiary at Zwickau in 1850, and in its earlier management exhibited exaggerated kindness to its inmates. Both the cellular and the associated systems obtain.

Würtemberg has accepted the cellular system. There are prisons for females at Heilbronn, and for males at Ludwigsburg and Stuttgart; in Würtemberg itself the *régime* is collective.

7. *Holland* has followed her nearest neighbour Belgium, and has now at command separate cells sufficient to receive the whole number of her prison population. The system of unbroken seclusion, prolonged to five years, is maintained with strictness. The prisons of Alkmaar and Breda have been enlarged, and the new buildings exhibit all the most recent improvements: the cells are lighted with electricity, perfectly ventilated and warmed, and furnished with every convenience. Prison labour embraces all kinds of handicrafts, and the prisoners' earnings are divided into three portions—one of which goes to the State, a second is at the disposal of the prisoner while incarcerated, or of his family outside, a third is paid him on discharge. This system obtains throughout the Dutch prisons at The Hague, Rotterdam, and elsewhere.

8. *Italy.*—Although accepting the principle of cellular imprisonment, Italy has not adopted it largely, partly from want of funds, and not a little because the current of thought has set against it, one leading criminologist, Enrico Ferri, having stigmatized the separate cell as "the greatest crime of the 19th century." In the 188 central prisons appropriated to accused persons and those sentenced to quite short terms there are only 13 on the cellular plan, and three others have a cellular quarter. The same applies in the smaller local prisons known as *i mandamentali.* The really penal establishments are 77 in number, the great *ergastolo* of San Stefano being one. Agricultural labour for convicts has been tried in colonies of *coatti* (or those provisionally released) planted out in the islands of the Italian archipelago. There are three of some importance upon Pianosa, Gorgona, and Capraja, one also on Monte Cristo and in Sardinia, several at Castiadas near Cagliari, at Bitti and Tre Fontane. These colonies are said to have been largely self-supporting, to have raised wine, cereals, and stock, and to have added to the development of the country by road-making, land reclamation, the building of breakwaters and river dams. Another view is that these colonies of *coatti* are a curse to the country, that their denizens live for the most part in idleness, that they set discipline at defiance, and terrorize their neighbourhoods. A marked feature in Italian criminality is the steady increase of recidivism, traceable by some to the faulty and demoralizing prison system of the country; others blame the practice of imposing sentences too short to be deterrent or to admit of the improvement of the offenders. A later experiment in the coercion of the recidivist, whereby the most determined were exiled as *coatti* to Assab in Abyssinia, where they were subjected to a very rigorous *régime*, lasted only eight months, as the whole number within that time had died or were invalided. Many Italian prisons, especially those of Naples, Venice, Parma, Mantua, Cagliari, and other large towns, are said to be of a most unsatisfactory character, and the penitentiary of Civita Vecchia is still more strongly condemned as a hotbed of vice.

9. *Norway and Sweden.*—Prince Oscar of Sweden was one of the earliest adherents of cellular imprisonment, and at his urgent representation penitentiary reform was warmly espoused in 1841. His influence is still felt, and the system in force in Norway and Sweden is progressive from strict separation to work outside the cell. There is a good prison at Christiania, another at Bodsfaengslet, and a fortress prison on the associated principle at Akershus for life-prisoners and recidivists. Serious crime in Norway tends to diminish, but the lesser offences have increased considerably, while reconvictions are very numerous, and the percentage of recidivists is for thefts alone from 34 to 35. Sweden, which adopted the cellular system in 1842, has now cells sufficient for prisoners sentenced to two years and less. There are three principal central prisons, one at Langholm near Stockholm, a second at Malmö, and the third at Nya Varfet near Gothenburg. In these as well as in the departmental and local prisons the system is one of complete isolation by day and night, but for sentences of more than four years the rule is associated work in the open air, with night separation. The cellular system is being extended to the prisons of Norrkoping and Gothenburg. In no case does the rule of cellular separation last beyond three years. It is claimed that the number of convictions is on the decrease in Sweden, but recidivism is frequent, amounting to 30 per cent. of the whole. A very substantial growth of juvenile crime is officially recorded in Sweden. One excellent agricultural colony for youthful offenders exists at Hall.

10. *Portugal.*—There are three or more cellular prisons at Lisbon, Coimbra, and Santarem, and the system of strict separation when first adopted in 1884 was expected both to amend and deter. These hopes have proved illusory, although the imprisonment has been prolonged to eight years for most serious offences. Deportation is a penalty always included in the Portuguese code, and it is still practised under the plea that it will regenerate the individual and develop colonization, but the results are unsatisfactory. There are now three penal colonies on the west coast of Africa—Mossico, Nana Candongo, and Caznengo in the province of Angola; and liberated convicts there are granted concessions of land. Depôts of exiled convicts exist also at Loanda and Benguela. Transportation has been decreed for recidivists, the *relegués* of the French law, but no very sanguine hopes are held of the success of the system.

11. *Russia.*—The subject of penal discipline in Russia covers a wide area, owing to the inclusion of political with purely criminal offences, the enormous number for whom prisons are needed under existing laws, and the severe character of the penalty most largely inflicted. The total prison population for whom accommodation is required amounts to 100,000 males and 13,000 females, a total which does not include children who accommpany their parents. For these vast numbers 883 prisons exist, nearly all of them till quite lately disgracefully bad and terribly overcrowded. Drastic reform was imperative, and between 1885 and 1891 eleven millions of roubles were spent on new buildings and the improvement of the old. The new cellular prison, "the Central," of St Petersburg, is a model of construction, with all the latest appliances; but the Belgian cellular *régime* is enforced with uncompromising severity. For some 300 years Russia has employed Siberian exile as almost the only method of secondary punishment, but at last sentiment has declared against a system which has inflicted countless sufferings upon hundreds of thousands, and by transporting some 30,000 souls annually has added 50 per cent. of the criminal class to the population of Siberia. But the Government would not surrender the principle of deportation, and as a later experiment has directed the stream of exiles by sea upon the semi-arctic island of Saghalien, with the object of creating a new great penal colony upon its inhospitable shores. The attempt appears to have been a failure. The island has proved quite unsuitable, owing to the rigours of the climate, the poverty of the soil, and the scarcity of food. Great administrative errors were made, the wrong sites for settlement chosen, the wrong persons—the aged and weakly—too largely selected as colonists. The moral and social condition of the convict population is reported to be abominable—drink, gambling, and the worst vices being everywhere prevalent. A high Russian official has thus summarized the situation: "The life led by the convict exiles at Saghalien is a frightful nightmare. It is a medley of debauchery, insolence, and impudence, coexistent with true suffering and indescribable privations." The general conclusion arrived at by competent authorities is that Saghalien is "a ghastly failure." The day cannot be far distant when a more intelligent system will replace all these costly and fruitless experiments.

12. *Spain.*—After many abortive attempts and long years of neglect, Spain took up penitentiary reform seriously in 1876, in which year a new cellular prison to accommodate 1000 souls was decreed for Madrid. Since then eighteen cellular prisons have been built and others designed. *Presidios*, or prisons for long terms, akin to the British convict establishments, exist throughout Spain. In them a harsh, merciless system prevailed, and prisoners' labour was leased out to contractors. *Presidios* beyond the confines of the kingdom have been maintained for long years, as at Melilla and notably at Ceuta. The system varies between great severity and excessive leniency. At Ceuta there is an average of 2500 inmates sentenced for life or long terms (*cadena perpetual* or *cadena temporal*). At first they are kept in close confinement, and then granted liberty, at first conditional, but afterwards complete, except for having to remain in Ceuta.

13. *Switzerland.*—The cantonal constitution of Switzerland has produced great variety in penal methods. Some are quite abreast of the best modern ideas. Cellular imprisonment is very generally the rule. There are excellent prisons at Geneva, Zürich, Neuchatel, Basel, Lausanne, and Lensburg. In the canton of Bern

the progressive system is the rule, with strict separation in the first stage, followed by labour at large and intermediate prisons. In the canton of Ticino there is a good cellular prison at Bellinzona, and the longest term of strict separation is for three years.

14. *United States.*—The penal system of the United States is perhaps the most advanced and also the most backward in the world. At one end are the numerous bad county gaols, and the horrors of the convict lease system in the Southern states, now nearly extinct; at the other the modern and well-equipped reformatories such as Elmira and Concord. The worst feature is the indiscriminate association sometimes seen of all inmates, bond and free, the convicted and accused; even witnesses against whom there is no shadow of a charge are sometimes imprisoned among felons. Nor is it only in distant corners of the great continent that this criticism applies. The local gaol in the city of New York, "the Tombs," a house of detention for prisoners awaiting trial, was described only a few years ago in an official report to the state Legislature as "a disgrace. . . . It is defective in every modern appliance. It is dark, damp, and ill-ventilated . . . . worst of all is the hideous system of keeping two or three men in a cell . . . . a means of indescribable torture to a decent man, and a prolific source of vice and crime to a criminal. Such treatment of dogs would be gross cruelty." This building has since been pulled down, a new and better one taking its place, and at least the worse features referred to in the official report have been done away with. The administration of prisons rests mainly with the state authorities, and there is no federal or general system which would introduce uniformity of treatment. Some of the state prisons are models of cleanliness and good order, built on the best and most imposing lines, with large, comfortable cells and an abundance of light and air. The earnest desire of most prison administrations is to develop industrial training and trade profits side by side with mildness of treatment. The latter sometimes lapses into methods which are not usually thought compatible with prison discipline, such as the permission to play on musical instruments, the holding of concerts, the privilege of smoking and chewing tobacco, of receiving baskets of provisions, novels, and newspapers from friends outside. The actual effect of prison treatment upon crime is doubtful. (A. G.)

Pritchard, Charles (1808–1893), British astronomer, was born at Brixton on 28th February 1808. At the age of 16 he was taken away from school and left practically to his own resources. Two years later he was enrolled as a sizar at St John's College, Cambridge, where he graduated in 1830 as fourth Wrangler. In 1832 he was elected fellow of his college, and in the following year he was ordained, and became headmaster of a private school at Stockwell, a post which he resigned in 1834 to undertake the headmastership of Clapham Grammar School, which he held till 1862, when he retired to Freshwater, in the Isle of Wight. For the next seven years he took an active interest in the affairs of the Royal Astronomical Society, of which he became honorary secretary in 1862 and president in 1866. His career as a professional astronomer began in 1870, when he was elected Savilian professor of astronomy at Oxford. At an age when most persons would have been looking forward to relief from the labours of an active life, he not only embarked with enthusiasm upon his professorial duties, but set himself vigorously to the task of original investigation. At his request the University determined to erect a fine equatorial telescope for the instruction of his class and for the purpose of original research, a scheme which, in consequence of Warren de la Rue's munificent gift of several valuable instruments from his private observatory at Cranford, expanded into the establishment of the new University Observatory. At de la Rue's suggestion the first research undertaken by Pritchard was a determination of the physical libration of the moon, or the nutation of its axis, an investigation in which the photographic method seemed to offer conspicuous advantages. Some thousands of photographs were taken and measured; but although important conclusions bearing on the applicability of photography to accurate astronomical measurements were deduced in the course of the work, the final results with regard to the moon's libration were never published. In 1882 Pritchard commenced a systematic study of stellar photometry, a branch of astronomy in which up to that time very little had been done (see PICKERING). For this purpose he employed an instrument known as the *wedge photometer* (see PHOTOMETRY, STELLAR, and *Mem. R.A.S.* vol. xlvii. p. 353). In his *Uranometria Nova Oxoniensis*, published in 1885 at the Clarendon Press, this work was extended so as to include the stars of Argelander's Uranometria Nova from the North Pole to about − 10° declination. It is thus confined to stars not fainter than the sixth magnitude, and includes in all 2784 different objects. In recognition of this important contribution to stellar photometry he was awarded the gold medal of the Royal Astronomical Society in 1886, conjointly with Professor Pickering. On the completion of this research he determined, for the first time in the history of astronomy, to apply the photographic method to the determination of stellar parallax. With the object of testing the capabilities of the method, he took for his first essay the well-known star 61 Cygni, whose parallax had already been attacked by several investigators employing other methods; and although the accuracy of his results was afterwards seriously called in question, they agreed so well with those of previous investigators that he was encouraged to undertake the systematic determination of the parallaxes of stars of the second magnitude, the results of which are contained in the third and fourth volumes of the Publications of the Oxford University Observatory. Apart altogether from the value of the actual parallaxes obtained, this work must be considered an important contribution to astronomy, as showing the possibility of employing photography in such delicate investigations. When the great scheme of an international survey of the heavens was projected, he undertook a share in it. The zone between 25° and 31° north declination was allotted to him, and at the time of his death some progress in the work had been made. Pritchard became a fellow of New College, Oxford, in 1883, and an honorary fellow of St John's College, Cambridge, in 1886. He was elected a fellow of the Royal Society in 1840, and in 1892 was awarded one of the Royal Medals for his work on photometry and stellar parallax. His death took place on 28th May 1893. (A. A. R*.)

Prittlewell, a parish in the South-Eastern parliamentary division of Essex, England; the village is 1½ mile north-north-west of Southend. The railway station is on the Great Eastern Railway. Population (1881), 7979; (1891), 12,333; (1901), 27,181.

Privas, chief town of department Ardèche, France, 378 miles south-south-east of Paris, with terminal station on branch line from Le Pouzin on the railway from Lyons to Nîmes. It is situated near the Orwèze, here joined by the Mezayon and Chazalon. A college, normal schools, library of 5000 volumes, mineralogical museum, hospital, and lunatic asylum for the departments of Ardèche and Drome are the principal local institutions. Manufacturing establishments include several silk-mills, forges, and foundries. The rearing of silk-worms and the cultivation of the mulberry are widespread industries. The important mining concession of Lac yields some of the finest iron ore in France. There is much commerce in silk, tanned leather, game, chestnuts, and fruit preserves. Population (1881), 4203; (1891), 4012; (1901), 7561.

Privas, one of the strongholds of the Reformed faith, suffered terribly during the wars of religion. Ineffectually besieged by Montpensier in 1574, it passed in 1619 into the possession of a Roman Catholic noble. A general rising followed, and in 1629 it was besieged and taken by Louis XIII. and Richelieu. In revenge for its resistance the captors reduced it to ruins, and the king decreed that it should not be again inhabited. A few years later, however, some of the townspeople crept back, and it was again repeopled. Some ancient Gothic-fronted houses, which escaped the general destruction, are still standing.

Prizren, Prizrendi, Prezdra, or Perzerin, chief town of a sanjak in the vilayet of Kossovo, European Turkey, situated on the Bistrìtza, near its junction with the White Drin, 60 miles east of Scutari. Among the mosques is the ancient Servian cathedral of Sveta-Petka. The old royal castle has been restored. Besides a manufactory of firearms, the town has an active general trade. Population, about 35,000, almost entirely Albanian, and chiefly Mussulman.

Prjevalsk (Przewalsk), formerly Karakol, a district town of Russian Turkestan, in the province Semiryechensk, 8 miles from the southern coast of Lake Issyk-kul. Prjevalsky, the Russian explorer in Central Asia, died here, and a monument has been erected to his memory. It is a growing town, and had in 1897 a population of 7987.

Prjevalsky, Nikolai Mikhailovich (1839–1888), Russian traveller, born at Kimbory, in the government of Smolensk, on 31st March 1839, was descended from a noble Cossack family. He was educated at the Smolensk gymnasium, and in 1855 entered an infantry regiment as a subaltern. In November 1856 he became an officer, and four years later he entered the academy of the general staff. From 1864 to 1866 he taught geography at the military school at Warsaw, and in 1867 he was admitted to the general staff and sent to Irkutsk, where he started to explore the highlands on the banks of the Usuri, the great southern tributary of the Amur. This occupied him until 1869, when he published a book on the Usuri region, partly ethnographical in character. Between November 1870 and September 1873, accompanied by only three men and with ridiculously small pecuniary resources, he crossed the Gobi, reached Peking, and, pushing westwards and south-westwards, explored the Ordos and the Ala-shan, as well as the upper part of the Yang-tse-kiang. By this remarkable journey he proved that, for resolute and enduring men, travelling in the Central Asian plateaux was easier than had been supposed. The Russian Geographical Society presented him with the great Constantine medal, and from all parts of Europe he received medals and honorary diplomas. The work in which he embodied his researches was immediately translated into all civilized languages, the English version, *Mongolia, the Tangut Country, and the Solitudes of Northern Tibet* (1876), being edited by Sir Henry Yule. On his second journey in 1877, while endeavouring to reach Lhasa through east Turkestan, he discovered the great lake Lob-nor (*q.v.*), which had not been visited by any European since Marco Polo. On his third expedition in 1879–80 he penetrated, by Hami, the Tsa-i-dam, and the great valley of the Tibetan river Kara-usu, to the vicinity of Lhasa, when he was turned back by order of the Dalai-lama. In 1883–85 he undertook a fourth journey of exploration in the wild mountain regions between Mongolia and Tibet. On these four expeditions he made collections of plants and animals of inestimable value, including nearly twenty thousand zoological and sixteen thousand botanical specimens. Among other remarkable discoveries were those of the wild camel, ancestor of the domesticated species, and of the ancestor of the modern horse (*Equus prjewalskii*), which some two hundred years ago inhabited Russia and Poland. Prjevalsky's account of his second journey, *From Kulja, across the Tian-Shan, to Lob-nor*, was translated into English in 1879. In September 1888 he started on a fifth expedition, intending to reach Lhasa, but on 20th October he died at Karakol, on Lake Issyk-kul. A monument was erected to his memory on the shores of the lake, and the Russian Government changed the name of the town of Karakol to Prjevalsk in his honour. (E. I. C.)

Process.—Until the last quarter of the 19th century reproductive processes, save as regards line reproduction, can hardly be said to have had an existence. Paintings, drawings, and engravings which it was desired to put into a form which by means of the printing-press could be multiplied indefinitely, had to go through a process of interpretation by an engraver or draughtsman, who on a metal plate, a block of wood or stone, gave a rendering of the original subject to the best of his power. The means at his disposal were lines and dots, which, varying in their thickness and proximity, expressed dark or light passages in the scheme of light and shade of the original. It will readily be understood how such interpretations would vary. An engraver with fine art instincts would produce a result as distinct in character as an engraving as was the original as a painting or drawing, and engravings were sought after as works of art, and treasured for their artistic qualities. But engraving of this kind took time. Years were devoted to the production of one steel or copper plate, while wood engravers who were artists could only work on a block when in the mood; and for that mood the publisher had to wait, and he grew impatient and was willing to accept rapid interpretation of originals by men who could produce them under other than artistic conditions. But the pain of the artist at the bad rendering of his original was often great, so that he, not less than the publisher, though for another reason, hailed the attempts that were being made to reproduce his work mechanically without the intervention of the translator or interpreter. The ideal of an artist would naturally be a reproduction of his work in facsimile, which retained all, or as many as possible of, the individual characteristics of his work; and to give him this was the aim of the school of wood engravers which originated in the United States and made a last stand to maintain the position of their art in the field of book illustration. By a system of extremely fine work the American wood engravers were able to keep much closer to the tones of an original than had previously been possible; but the result was obtained at the sacrifice of the artistic rendering of the best old engravings, and was so mechanical in its character that when it came in contact with a real mechanical process the engraving could not hold its ground, the enormous difference in the cost of production being a factor of sufficient importance in itself to make it impossible for the engraving to retain the field. A similar development had been going on in the other branches of engraving. The steel-plate engraver and the etcher, to whom had been entrusted the interpreting of works of art first produced in other forms, found themselves faced by mechanical reproductions in plate form which, while preserving more of the character of the original work, were produced in much less time and at a greatly reduced cost. It has thus come about that the last quarter of the 19th century witnessed the dispossession of the hand engraver from the field of interpretative engraving, and the occupation of his position by the chemist and the mechanician. (See Engraving.)

Definition.

The term "process," which has come to be applied to all mechanical reproductions, is a somewhat unfortunate one, inasmuch as it is descriptive of nothing. From time to time various names have been given to its varying forms, indicative either of the name of the inventor or of some peculiarity of method. Zincography, Gillotype, Photogravure, Heliogravure, Heliotype, Phototype, Albertype, are illustrations of the kind of name given often to very slightly varying applications of the same principle, but usage has come to apply the term

"process" to any printing surface that is produced by chemical and mechanical means.

The whole of these processes may be arranged under three heads—1. Relief; 2. Intaglio; 3. Planographic.

1. Relief Processes.—An engraving in relief is one in which the printing surface stands up above the surrounding ground. Its typical form is presented by the movable letter of the letterpress printer. The history of its development is really the history of photography; for whilst attempts were made to obtain results without the aid of photography, by drawing upon plates with prepared chalk or ink, "rolling them up" with printer's ink and etching away the ground with acid, as in the case of Zincography, the real progress of all process has been upon the lines of photography; and to the two Frenchmen, Niepce and Daguerre, the first a mechanician and the second a photographer, may be attributed the origin of the modern mechanical and chemical processes. These two men were both born towards the end of the 18th century.

Speaking broadly, all the modern "processes" are the outcome of a discovery that a preparation of albumen and bichromate of potash could be hardened by exposure to light, and that as a photographic negative permitted the passage through it of light in varying degrees of intensity, so a film of the preparation placed under a negative was liable to be hardened in varying degrees according as the light affecting it was intense or otherwise. This discovery governs the production of process blocks or plates of all kinds. By its application relief blocks may be made from drawings or engravings executed in line purely, or from drawings, or engravings, or photographs which are rendered in graduated tones.

The methods of reproduction of pure line work differ greatly from those for the reproduction of originals in tone, and they must be described separately. As the first necessity in securing a good result is the suitability of the original to be reproduced, it is desirable to make clear the character of a good original. This should be of one tone or degree of colour all through. It may be all grey; it is better that it be all black. It may not be black in parts only and grey in others. The lines of an original may be of any variety of thickness, but in colour they must be uniform. It is necessary, therefore, for the draughtsman to see that he works with a good black ink, or ink which will tell as black when it is exposed to the photographic plate. Inks of a warm tone—that is, inclining to red or orange—yield better results than cold inks which incline to blue.

Line blocks.

It is found in practice that most prepared liquid inks have a tendency to lose their blackness by exposure to the atmosphere on the removal of the cork from the bottle. The ideal ink is one freshly ground from a dry cake of colour when beginning work each day. Indian ink is good if well ground and kept sufficiently thick to assure the necessary blackness. It has the advantage of not washing up when colour in washes is passed over it, but it must be used freshly ground. The addition of a little Indian yellow, burnt sienna or sepia, gives a warmth of tone to it and renders it photographically more active. Bourgeois ink, prepared by M. Bourgeois of Paris, appears to be prepared with the admixture of some warm colour with the black base. It is a good ink for the purpose, and is prepared both in solid and liquid form. Lamp-black gives good black lines; so does ivory black, which is warmer in tone than lamp. Higgins's Indian Ink or American drawing ink is an American ink made in liquid form which has the reputation of not fading by exposure, as most others do. Stephens's Ebony Stain is a fine black medium which does not clog the pen; if it thickens and dries, it cracks off and does not corrode the pen. The pen is not the only medium by which originals may be prepared for reproduction by line process. A brush brought to a fine point is much preferred by some artists, as it yields a line less monotonous than that given by a pen, though the brush cannot be used so freely. The paper used should be smooth and as white as possible. A paper is made with a surface coating of white chalk, which admits of the use of a scraper to remove lines or to break them up. It is not possible to lay down a rule for the amount of reduction to be made when photographing for the reproduction; the finer the drawing the less should be the reduction made. Usually a reduction to three-quarters or two-thirds the size of the original is sufficient, but experience is the only guide. Sometimes, where the lines are very fine and the drawing minute in character, an enlargement is desirable. Where drawings are reduced too much, there is a tendency for the spaces between the lines to fill up, and to give a coarse, heavy result. Faulty drawing is not lessened by reduction. On the contrary, the fault becomes more evident, so it is desirable to make all necessary corrections in the drawing.

The original drawing which has to be reproduced is photographed to the size of the required block. The negative taken is absolutely dense except where the lines of the drawing have affected it, and these are absolutely clear, admitting the unrestricted passage of light through them. A piece of planished copper or zinc is prepared or made sensitive to light by a preparation of albumen or gelatine and bichromate of potash spread upon its surface. The negative is laid upon the sensitized metal and placed in the light in the way an ordinary photograph is printed. The light passes through the transparent lines of the negative and hardens the bichromate of potash beneath it. Both negative and plate are then taken into a dark room, where the metal plate is rolled with an inked roller, placed in a bath, and allowed to soak until the albumen and bichromate become so softened everywhere, except where the light has hardened them, that they all wash away, and nothing is left but the hardened lines. The lines are dusted with asphalt, which by heat is melted on to them, and makes a ground which resists the action of acid. A coat of varnish is put over the back and edges of the plate, to protect them from the acid also, and only the spaces between the lines on the surface are left free to its action. The plate is then placed in an acid bath, which eats away the metal wherever it is exposed; but it leaves the lines of the drawing, which are protected by the hardened film standing up above the eaten or etched surface; and these lines, which correspond to those of a wood engraving, are the printing surface of the plate. The plate is mounted on a wood or metal block, the whole is made type-high, and it can then be used along with type in the printing-press.

Various devices have been resorted to that effects of tone may be obtained by means of the simple line process. Grained papers with a surface of chalk, upon which are printed close-ruled lines crossing at right angles, or rows of dots; these give the papers a heavy, flat "tone," upon which a drawing can be made in pencil, chalk, or ink, and gradations of tone introduced by means of scrapers prepared for the purpose, which remove partially or entirely the black ruled lines or dots, leaving, if desired, high lights of pure white. A drawing on such paper consists of lines or dots, a combination of the original lines or dots of the paper and those of the drawing itself, the scraper splitting up lines into dots or removing them altogether. The result is quite easily reproduced by the line process.

Another method of obtaining a combination of tone and line by the line process is by the use of what are known as Day's "shades," or shading mediums. They are transparent films of gelatine which have upon them lines or dots in varying combination in relief, so that they can be inked up by a roller. When placed over a drawing, their transparency enables the operator to see exactly what passage he is dealing with, and he can by means of a burnisher impress the lines or dots of the shade upon any passage of the drawing; these lines or dots then become part of the drawing, and are reproduced in the usual way.

Pencil or chalk drawings upon simple white-grained paper, where the pencil or chalk passing over the ruts or hollows in the paper makes a mark on the top of the grain only, are also reproducible by the line process, but such drawings are apt to be unequal in colour and difficult to deal with.

This difficulty led to the invention of a process by Mr Henry Matheson, who, not having the capital to work it, joined the late Mr Dawson, sen., whose

sons continued to work the process with Mr Matheson under the name of the Swelled Gelatine Process. It is based upon the discovery that gelatine, sensitized with bichromate of potash, swells when placed in water, and swells in proportion to the amount of light to which it has been exposed. A negative taken from a drawing which varies in tone, not being thoroughly black all through, varies in the quality of its transparent lines and dots; and when a piece of paper or glass coated with sensitized gelatine is exposed to the action of such a negative, it is affected according to the amount of light the negative allows to pass. After making a print on such paper or glass, it is placed in a dish of water and the surface allowed to swell, which it does in varying degrees, the portion unaffected by the light absorbing most water and swelling most, the lines of the drawing not swelling at all. This swelled print is then placed in a frame, and a preparation of plaster is poured upon it to make a mould of its surface. When this has set and the gelatine has been removed, this mould is filled with a preparation of wax, which sets in a few minutes sufficiently for it to be released from its plaster mould. Additional wax is built up when necessary upon the "whites," as they are technically called—that is, the passages which represent what will be the hollows in the block—so that these may be as deep as possible; and the wax mould is then handed over to the electrotyper, who deposits a layer of copper upon it. The lines and dots of this copper block, which when finished is backed up with metal and mounted, vary slightly in height, the result being that the slightly lower dots do not come so closely in contact with the inking roller or with the paper, and so produce a grey impression corresponding to the greyness of the original drawing.

Swelled gelatine process.

The drawback to the use of the process is that it is about three times as costly as the ordinary process. It is a method much used for the reproduction of line and stipple engravings, where fine dots and lines are apt to be printed in delicate tones. The finest results by this method are producible, however, by omitting the plaster mould and wax-cast stages, and by coating the sensitized gelatine with plumbago or other impalpable metal preparation which will enable it to receive a copper deposit to qualify it to take its place in the electrotyper's bath, and so to get the needed thin coating of copper from the surface of the gelatine itself; but this needs to be done with the greatest of care, and is still more costly.

The invention of line processes only stimulated the efforts to find out means whereby tones might be reproduced on blocks or plates that could be printed along with type in the ordinary rapid printing-press. It is only possible to approximate to the printing of a flat or graduated tone by producing a surface that is broken up into some sort of granulated surface which shall present a series of lines or dots that, when inked and impressed upon paper, shall by the variations of proximity and size give the impression of an unbroken tone. This necessitates the lines or dots being so small that the eye shall not at a glance appreciate the broken-up character of the surface of the block. Many efforts resulted in the production of what is known as the screen, which itself was only made possible by the invention of ruling machines of a delicacy previously unknown. A screen is made by coating a sheet of glass—which must be flawless both as to body and surface—with a composition analogous to the ground used by an etcher to coat his plate before drawing upon it with his needle. The glass so coated is placed in an automatic ruling machine, of which the ruling point is a diamond, and which can be adjusted so finely as to produce between 200 and 300 lines to the inch. The lines are ruled diagonally on the glass, and at mathematically equal distances from each other. The sheet of glass, after ruling, is treated with acid, like the plate of an etcher, and the lines where the ground is cleared away by the diamond point are etched or bitten into it. The plate is cleaned up and an opaque dark pigment rubbed into the lines. Two such ruled sheets of glass are placed face to face, with the diagonally ruled lines crossing each other at right angles, the result being a medium or screen containing innumerable little squares of clear glass through which the light can pass, which it cannot do through the ruled lines, which are filled by the opaque pigment. To produce a half-tone block from a picture, a black and white drawing in tone, or a photograph, a negative is exposed in the camera in the usual way, with this screen quite close to it but not in contact; and the subject is photographed on to the negative through the screen, and what is termed a screen negative is the result. It is a photograph of so much of the original as could affect the negative through the little clear squares of the screen, and represents the tones of it by innumerable dots and lines, the size and proximity of which are regulated by the fineness or coarseness of the screen used. In the early days zinc was the metal used for these half-tone blocks; but experience showed that though more difficult to etch to the necessary depth, the closer, denser texture of copper rendered plates of this metal much more suitable for the production of the best blocks, and zinc now is used only for inferior blocks. Whichever metal may be used, a sheet of it, most carefully planished, is sensitized with a coating of gelatine or fish-glue and bichromate of potash, and exposed under the screen negative to the action of light, as in the ordinary method of photographic printing. The action of the light, as previously explained, hardens the gelatine film, the portion not so hardened being removable by water. The plate with the hardened lines and dots is exposed to heat and they are burnt in upon it, to enable the means of resistance to be set up to the action of acid. The plate is placed in an acid bath, which is rocked to and fro to prevent the air-bubbles produced by the acid action from settling upon the surface of the plate and interfering with the regular action of the acid. Wherever the surface of the plate is free from the lines and dots, it is bitten away by the acid, and the lines and dots are left in relief. This first biting in the bath produces a rather rough general impression of the original, and is termed "rough etching." To produce finer results, and to bring out the contrasts of black and white so necessary to a good reproduction, the block has to go through processes of stopping out and rebiting similar to those of etching an intaglio plate. This "fine etching" calls for the artistic taste and judgment of the craftsman; and with a good photograph to work from, the final quality of a block will turn almost entirely upon its treatment by the fine etcher.

Half-tone processes.

One risk that has to be most carefully guarded against is the underbiting of the lines and dots which form the printing surface. As soon as the acid has eaten its way downwards past the protecting surface film, it will attack the sides of the upstanding dots as well as the ground that supports them, with the result that they become weakened and rendered liable to break off in the process of printing, as well as to make the obtaining of electrotypes from the blocks a matter of extreme difficulty, the underbitten points breaking or tearing away in the mould. To avoid this underbiting in the course of etching and re-etching, a fatty ground is laid over the surface of the block each time it is etched; by exposure to heat this ground is sufficiently melted to permit of its running down the sides of the upstanding points, and so giving them the required protection. When completed, the copper plates are mounted on wood or metal blocks, type-high, for use with type in the printing-press.

The name by which this process of making tone relief blocks is most generally known is the Meisenbach process, from Herr

Meisenbach, of Munich, who first brought it prominently forward in Europe. It was greatly improved upon by Messrs Angerer and Göschl, of Vienna; but the great advance was due to the improvements made in the manufacture of the screens by Mr Max Levy, of Philadelphia, who made it possible, by his improvements in the ruling machines, to produce screens of a fineness not previously practicable.

The chief objection to this process is its inability to reproduce the extremes of expression employed by the artist in black and white: actual white is impossible, and delicate tones, such as are characteristic of skies, are destroyed by the cross-bar lines of the screen, which cover down all light passages and rob the reproduction of that brilliancy which characterized wood engraving. It is true that the addition of hand engraving can be resorted to in the case of the process block, and lights and other varieties of tone and form introduced, but this can only be done on blocks of very fine texture, and the cost of reproduction is greatly increased by the introduction of such handwork by the engraver.

The most important development of the half-tone process is in the direction of the reproduction of works in colour rendered possible by the researches of artists and scientists. It will be sufficient here to explain the general principles upon which the three-colour process is based. It has long been an accepted theory that all combinations of pigmental colour exhibited in pictures, flowers, or any other form resulted from a combination in varying quantities of what are known as the three primary colours, red, blue, and yellow, and that if it were possible to get at the exact amount of each colour necessary to its formation, any possible tone of colour might be produced by blending the primary colours in the necessary proportions. But the human eye has not been able to analyse tones of colour with sufficient accuracy to settle what proportion of each primary colour goes to the making up of a given tone. Such analysis, however, has been rendered practically possible by photography. The white light of daylight is the result of a combination of rays of coloured light, which for our purpose we may describe as being rays of blue, red, and yellow. It is interesting to note that the combination of these three colours, in varying proportions in the form of rays of colour, combine to produce white light; but the combination of the same three colours in the form of pigment results in black.[1] The prism which breaks up the combination of coloured rays shows that when the light rays do not contain the necessary combination of the rays of the three primary colours, white light no longer results, but that separated they give "all the colours of the rainbow." The various colours of objects are the result of the fact that surfaces have the power of absorbing and reflecting certain of the coloured rays only which strike them, and that they are unaffected by the others. Thus the green leaf absorbs and reflects the blue and yellow of white light, leaving the red unaccounted for.

Three-colour blocks.

The photographer has utilized these facts and theories by inventing *filters* of various substances, which, owing to their nature, absorb and refuse passage to certain coloured rays, while permitting the passage of others, just as a charcoal filter will keep back certain substances in water, but allow the water itself to pass through it. So a photographic filter of a certain colour will absorb and stop the passage of red and blue rays, while permitting the passage through it of the yellow. Another filter will similarly absorb and stop the yellow and red rays, while permitting the passage through it of the blue. It will then be readily perceived how, when a picture or other coloured object is placed before a camera, with one of these filters between it and the exposed negative, the rays of light of the colour which can pass through the filter to the negative will be the only ones which can affect it, and that it is possible in this way to secure on three separate negatives a record of the blue, red, and yellow rays which are reflected from its coloured surface by any object placed before the camera. These three negatives may then be used in the ordinary way, and, by means of the ruled screen already described, three half-tone blocks produced, which, when printed one over another with coloured inks corresponding with the three primary colours, give approximately a reproduction of the original in its true colours.

It was as far back as 1861 that the suggestion was made, at the Royal Institution by Mr J. Clerk-Maxwell, to reproduce objects in their natural colours by superimposing the three primary colours. Later Baron Ransomut, of Vienna, Mr Collen, a gentleman who taught drawing to Queen Victoria, and two Frenchmen, Messieurs Chas. Cros and Ducos du Nauron, carried on the idea and made experiments with the aid of photography, which were still further developed in Germany by Professor Husnik, of Prague, Dr Vogel, of Berlin, and others; but it was in America that the first three-colour blocks for letterpress printing were made, Mr Ives, at Philadelphia, being their maker in 1881.

This three-colour relief process is yet in its infancy, but already its development is such that no doubt remains as to its ultimate success. The first great practical difficulty which had to be overcome was to produce three screen blocks which could be printed one over the other. Were the screens of each block used at the same angle, the lines and dots would print on the top of one another; but a great deal of the colour result depends upon a considerable proportion of each colour being on the white paper. Artists and people who work with colours know well that much purer and more brilliant results are produced by placing touches of colour side by side than one over another: small patches of red and blue placed side by side yield to the eye a purple of much greater purity and beauty than the same touches of colour worked one over the other. Consequently it was found necessary to turn the screen at a different angle for each block, so that the lines should not fall on each other but should cross each other; but the risk of this is that, used at certain angles, the crossing of the screen lines will produce what is known as the *moiré antique* result. Dr Vogel took out a patent in Great Britain for the process, and he therein stated that the screens should be used at certain stated angles. He also proposed to use single-line screens, similar to those used by Mr Ives at Philadelphia, instead of cross-line; but it has since been found that the cross- or double-line screens can be used with better results than single-line; and that the angle at which they can be used may vary, but it is well that the lines should cross each other at an angle of somewhere about 30°.

Colour-filters.

Filters are made in a dry or wet form. The dry filter is made by spreading a film of gelatine or collodion, tinted by an aniline colour, upon a piece of glass. The wet filter is a cell or trough made of two sheets of glass, sealed all round and filled with water tinted with an aniline dye or colour. The accuracy of the tint of the colour-filter may be tested by the spectroscope, or by an instrument invented by Sir William Abney, and known as the Abney Colour Sensitometer. This is a theoretical test. The practical test is by photographing through them patches of blue, red, and yellow. If, for example, the filter for blue records the full strength of blue with the full strength of the colour of the negative, while giving no record at all of the red and yellow, it is practically a true filter. It is possible to treat the negatives themselves so as to render them more sensitive to the special colour they are intended to record. Indeed, it is necessary to see that the filters and the negatives are in working harmony. Different makes of plates demand different colour-filters. For full information as to screen-making the reader may be referred to a paper by Mr Ives in the *Photographic Journal*, vol. xx. No. 11. The efforts of the ink manufacturers have had to be directed to the production of what are termed "neutral" primaries—that is to say, a blue pigment absolutely free from any

[1] As a matter of scientific analysis, the primaries of white light are red, green, and purple, but the pigmental primaries are red, yellow, and blue; and as we are in this paper dealing with pigmental results only, it will simplify the theory, and render it more intelligible, if we treat it from the pigmental point of view, and speak of the primary colours of the artist rather than those of the scientist.

Stages of Three-Colour Printing.

THE five prints shown on this Plate represent the various stages in the three-colour process. I., II., and IV. show the primary colours used—yellow, red, and blue. The only one of these, however, which is printed as shown is I. in yellow, II. and IV. being only printed here to give the colours used. The second stage of the process is to print a red plate over I., the result being shown in III. In the third stage a blue plate is printed over III., the result being the finished picture, shown in V.

[The picture used to illustrate this process has been reproduced, by permission, from Mr Mortimer Menpes's "Japan."]

V.

taint of red or yellow, and, similarly, a red and yellow free from admixture with their complementary colours. The preparation of these colour-filters calls for great perfection of quality in the materials employed, and great accuracy in the using of them. The glass, whether for the dry or wet filter, must be absolutely flat as to its surface, without waves or irregularities of any description, and its two sides must be absolutely parallel; in other words, it must be absolutely uniform in thickness throughout. In the wet filter the glasses forming the sides of the cell or trough must be parallel to each other.

Coloured glass is sometimes used in combination with the tinted collodion, but there is no particular advantage in this, because two glasses are always used in the making of a filter, and each one may, if desired, be coated with different dyes and afterwards cemented together with Canada balsam.

The following dyes or their equivalents form a basis for nearly all three-colour filters:—

For the red printing negative	Brilliant green. Brilliant yellow.
,, blue ,, ,,	Cochineal red. Brilliant yellow.
,, yellow ,, ,,	Methyl violet. Naphthol green.

The first dye named is the base colour in each case, the second is employed in small proportions to produce the required modification of tint.

The theory of this three-colour process is that the same three colours shall be used for the printing of every subject; and there is no doubt that if the filtration were perfect and the printing inks absolutely pure, the theory would work out fairly correctly in practice; but at present there is room for improvement in both these matters, and it is therefore often found desirable to print special subjects with special pigments, which makes it difficult to print several subjects together. Special care is called for on the part of the printer. There must be the most perfect register of the three subjects, otherwise a blurred effect results; there must be constant watchfulness to see that there is no excess of ink of any one colour, or the whole scheme of colour will be destroyed. An "eye for colour" is perhaps hardly to be looked for as one of the qualifications of a machine-minder, and yet without the oversight of some one with such an eye colour-printing cannot be successful. This three-colour process has been a rather long time in taking the place it deserves, and nothing has so tended to retard it as bad printing. For some time past good blocks have been obtainable, but in the hands of ordinary printers they have yielded but indifferent results. There is great need for the technical training of the men who have to oversee such work. It is hardly to be expected that the untrained eye of the ordinary printer should be successful where the work requires the cultivated judgment of an artist. There is one other necessity for success in all tone relief work, whether block or colour, and that is the use of the right quality of paper and ink. The blocks are so delicate they soon fill up if an excess of ink is used. Ink of a good quality can be used in much less quantity than common kinds, but it must be impressed upon paper that is sympathetic and will "bear out" the ink.

Need of careful printing.

The best results can be obtained only with the use of what is known as "coated" paper. It is paper which, after manufacture, is passed through a bath of a preparation of china clay, which by means of brushes is rubbed into the surface of the paper. When dry the surface takes a high polish, and is sensitive to the smallest amount of ink. The polish of this coated paper is objectionable to many readers of illustrated books, and the clay adds considerably to its weight.

2. Intaglio Processes.—An intaglio engraving is one in which the printing surface is sunk below the surrounding portions of the block or plate; the lines or dots—pressed, cut, or bitten into the surface—holding the ink, which is to be impressed upon the paper when the original surface of the plate is wiped clean. The old-fashioned steel engraving may be taken as the type of an intaglio plate, in which the lines which printed were cut into the surface of the plate, instead of being left standing up in relief, as in the case of a wood engraving.

Photogravure is the name by which the many processes are generally known by means of which intaglio engravings are made mechanically, *heliogravure* being another name for the process, or special application of it. Photogravure reproduces the tones of photographs or drawings, and gives the nearest approach to a facsimile reproduction that has yet been arrived at. Gelatine bichromatized, as in the case of relief blocks, is the medium by means of which the photogravure plate is produced; but as the screen is not used in ordinary work, it is necessary to produce an ink-holding grain in some way upon the plate. This is done by allowing a cloud of bitumen dust, raised inside a box, to settle upon the surface of the plate; it is fixed by heat, which, though insufficient to melt it, is enough to attach the fine grains to the plate. Over this prepared surface is laid the film of bichromatized gelatine, upon which is printed the subject through a glass positive; the usual hardening process takes place by the action of light, followed by a washing out of the unhardened portions of the gelatine. The plate is exposed to the action of perchloride of iron, which attacks it most strongly in the least exposed parts, but which cannot eat it away in broad flat masses of dark, even in the non-exposed portions, owing to the existence of the bitumen granulation, which ensures the keeping of a grained surface even in the darkest passages.

Photogravure is a costly process to employ for illustration. The plates have to be printed slowly, with much hand work, as in the case of etchings. It is the printing that makes its use expensive, rather than the making of the plates; and as each plate must be printed separately and on special paper, it cannot be employed with type, like relief blocks.

It will be readily understood that there is much uncertainty about the production of plates by the photogravure method; and although great improvements have been made in the process, it is often necessary to produce several plates before a satisfactory one is obtained; and even then a good deal has to be left to the retoucher, who with his roulette, burnisher, and graver must give qualities of transparency and brilliancy and intensity that are missed by the mere mechanical operation. In all these reproductive processes the more artistic the workman, the better the result; this is especially true of photogravure, in which the aim is to come very much nearer to the original work of the artist designer than in the less perfect processes.

The method of M. Rouisillon, which was adopted by Goupil in the production of photogravure plates in the early days of the process, was to prepare the surface of the plate with a secret preparation of certain salts, which crystallized under the action of light, so that when exposed under the negative the surface was broken up by this crystallization more or less, according to the amount of light the negative permitted to reach it. The plate with its crystallized surface was then electrotyped, and the electrotype was the plate used for printing. It was a deposit process, as opposed to an etching process.

Photogravure plates are made also by the use of the grain screen, in which the reticulations of the screen take the place of the bitumen powder in producing a grain; it is the inversion of the method by means of which points and lines are produced in the relief block. It has not, however, come much into favour, probably owing to the greater coarseness of the grain and the consequent loss of softness in the tones. An application of this method has, however, been made in the most recent development of the use of screen plates in what is known as the Rembrandt Intaglio Process. It is the property of a firm at Lancaster, and is a secret process; but the secret lies more in the press by which the plates are printed than in the plates themselves, which are intaglio plates made with a very fine screen and bent to a cylinder. The attempt to print photogravure plates by machinery was made many years ago, but it was given up because the plates were so shallow they would not stand the wear and tear, and their life was too short and

Rembrandt intaglio process.

the results too indifferent; but the use of the grain screen renders possible stronger, deeper plates, that will stand harder wear. While we are unable here to describe actually the machine in use in Lancaster, there is little doubt it is some form of the machine used to print wall papers, in which there is a central cylinder engraved with the design, inked by rollers with which it comes in contact. The ink not only fills up the intaglio or sunk portion which has to print the design, but covers as well the whole surface of the plate. To clean this surface, leaving ink only in the sunk dots and lines, another metal cylinder is employed, ground and grooved somewhat like the shaft of the common steel of the dinner table used to sharpen knives, the grooved surface of which, passing over the engraved cylinder, scrapes clean its inked surface, leaving ink only in the sunk portions, which will, as the cylinder comes in contact with the paper, deposit itself and print the picture. The results produced by the Rembrandt intaglio process are softer and smoother than those given by photogravure, and they are free from the gritty qualities which occasionally characterize photogravure; but they lack the brilliancy and depth of the latter. The process on the whole is less costly to use, mainly because the printing is so much more rapid, and is turned out by a machine instead of by hand.

Monotype. The monotype is not a new, but a revival of a somewhat old, method of reproducing on paper a painting by an artist. The design is executed on a plate by means of brushes, fingers, or other tools, with paint or printer's ink. On the completion of the painting, paper is laid upon it, and plate and paper are together passed through a press, when the ink or colour is transferred to the paper. One impression only is possible, hence the name of the process. A method has been devised by Professor von Herkomer, R.A., for dusting the painting while still wet with a fine metallic powder, which renders the surface sympathetic to a copper deposit when it is placed in the galvanic bath, by which means an electrotype of the painting, with its varying relief surfaces, is obtained, and forms a plate from which numerous impressions can be taken.

Electrotypes. The very large number of impressions it is often required to get from the etched surface of a block has made it necessary to devise means for preserving the original block, and to prepare and work from duplicates, which can be renewed when necessary. For this process the original is coated with a film of the finest plumbago (blacklead) powder before being placed face to face with a bed of soft fine wax, into which it is pressed. The plumbago prevents adhesion and facilitates the withdrawal of the block after contact with the wax. The wax mould which is thus obtained is suspended in a galvanic or electric bath in which sulphate of copper has been dissolved. The copper at once begins to deposit itself in metallic form over the face of the wax mould, and in a short time the deposit becomes thick enough, either by itself or when backed up with other metal, to be used as a block in the place of the original. The very fine nature of process blocks, and the necessity of obtaining perfect impressions from them, has led to the introduction of gutta-percha instead of wax as the medium for making a mould. It is melted and poured in a liquid state upon the block, and when cold can be removed without the risk attending the use of wax, which is apt to give way with the slightest lateral movement in the course of the separation of the block from the mould. Gutta-percha is much more tenacious, and being somewhat flexible, does not break and tear, as wax is liable to do. The whole process requires the greatest care in its manipulation, and on its success depends the final appearance of the artist's work in the printed page.

3. PLANOGRAPHIC PROCESSES, which include Photo-lithography, Woodbury-type, and other processes of printing from a flat surface, are described in vol. xxiii. p. 704.

Steel-facing. Steel-facing is resorted to where long numbers have to be printed from photogravure plates. The finest film of steel is deposited by an electric battery over the whole face of the plate, which it hardens and protects. This steel face in time begins to wear, through the constant pressure and rubbing incidental to the process of printing, and the copper begins to show through it. As soon as this happens, the plate is placed in an acid bath, in which the steel film disappears like dew from the grass before the heat of the sun. The plate itself being still intact, can be resteeled for further work.

The changes which have taken place in the form of illustrations have necessarily been accompanied by changes in the machinery by which they are printed.

Changes in machinery. Almost all the changes and improvements have been initiated in the United States of America, which country has taken the lead in all developments of printing machinery and processes. The vital change made in the interest of process block-printing is what is technically known as "hard packing." Before the introduction of process blocks, *the blanket* played an important part in all printing machines. It was a soft woollen sheet, which came between the plate or cylinder and the type and blocks, and modified the force of the contact between them. Owing to the increased fineness of the texture of the process block as compared with the wood engraving, it was found that the blanket was too coarse and soft a material, and that it interfered with the clearness and fineness of the printed result. Blankets of finer material were tried, with improved results; but at last the blanket was entirely discarded, the machinery was more accurately constructed, and the hard, finely polished steel cylinder, without any intervening substance save the sheet of paper to be printed, was brought in immediate contact with the type and blocks. The old soft blanket kept the cylinder or the flat press in contact with the type, in spite of the weak construction of much printing machinery. The new method of work made no allowances for such construction; and the new machinery, to meet the new conditions, had to be very perfect in manufacture. About the old machines there was a lack of solidity, which allowed vibration. Modern work demands absolute rigidity in the machine; and a chief characteristic of the best modern printing machinery is strength and solidity, admitting of precision of impression. Another change has been in the nature and treatment of the printing paper. Most elaborate methods were adopted in all large printing establishments for the moistening of the substance of paper before use. Most paper was printed on whilst damp; but damp paper had to disappear with the soft blanket, and a clay-surfaced paper was introduced with a highly glazed face in harmony with the polished steel cylinder which pressed it against the type and blocks. It is essential to this paper that it be dry when used; to ensure the best results with it, the paper should be kept some weeks or months before use, so that it may be absolutely dry, or seasoned. If printed on too soon, its surface tears away when in contact with the "tacky" ink: and instead of the ink being deposited on the paper, bits of the paper surface are left on the forms, and white spots appear in the impression. The bits of paper surface so deposited on the forms get inked as they pass under the rollers, and impress black spots on the sheets that come after. New and unseasoned paper accounts for much bad printing, and this form of badness is due to the change in material due to the necessities of modern process work.

Proctor, Richard Anthony (1837–1888), British astronomer, was born at Chelsea on 23rd March 1837. His father died when he was thirteen years old, and, being rather a delicate child, he was kept at home as long as possible by his mother, who attended to his education herself. On his health improving he was sent to King's College, London, from which he obtained a scholarship at St John's College, Cambridge. He graduated in 1860; but his position as 23rd Wrangler disappointed many of his friends, who had formed a high estimate of his abilities. While still an undergraduate he was privately married, a circumstance which may have contributed to the comparative failure at his degree. For some time he thought of taking up the profession of law, but having imbibed a taste for astronomy, and being impressed with the independence and importance of the position of an author, he decided to devote himself to that subject. He made his first appearance as a writer on astronomical subjects in an article on the "Colours of Double Stars," published in the *Cornhill Magazine* (1865). His first book—*Saturn and his System*—was published in the same year, at his own expense. This work contains an elaborate account of the phenomena presented by the planet, his satellites, and rings, a discussion of the various motions of the planet, and the possibility of life upon its globe. It was favourably received by astronomers; but although marked by a lucidity of exposition and enthusiasm for his subject which distinguish his later works, and although it possesses elements of permanent value as a contribution to astronomical literature, it had no great sale. He has left it on record that he intended to follow it up with similar treatises on Mars, Jupiter, Sun, Moon, Comets and Meteors, Stars, and Nebulæ, and had in fact commenced a monograph on Mars, when the failure of a New Zealand bank, in which he was a considerable shareholder, deprived him of an independence which would have enabled him to carry out his scheme without anxiety as to its commercial success or failure. Being thus obliged to depend upon his writings for the support of his family, and having learned by the fate of his *Saturn* that the general public are not attracted by works requiring prolonged attention and arduous study, he cultivated with success a more popular style. He wrote for a number of periodicals; and although he has stated that he would at this time willingly have "turned to stone-breaking on the roads, or any other form of hard and honest but unscientific labour, if a modest competence had been offered" him in any such direction, he attained a high degree of popularity as an exponent of astronomy, and his numerous works have had a wide influence in familiarizing the public with the main facts of astronomy, and have doubtless had far-reaching effects in stimulating an interest in astronomical subjects. His earlier efforts were, however, not always successful. His *Handbook of the Stars* (1866) was refused by Messrs Longmans and Messrs Macmillan, but being privately printed, it sold fairly well and paid expenses. For his *Half-Hours with the Telescope* (1868), which eventually reached a 20th edition, he received originally £25 from Messrs Hardwick. Although the work of teaching was uncongenial to him, he took pupils in mathematics, and held for a time the position of mathematical coach for Woolwich and Sandhurst. His position as a writer was, however, improving, and he became a regular contributor to *The Intellectual Observer*, *Chambers's Journal*, and the *Popular Science Review*. In 1870 appeared his *Other Worlds than Ours*, in which he discussed the question of the plurality of worlds in the light of new facts ascertained since the time of Whewell and Brewster. This was followed by a long series of popular treatises in rapid succession, amongst the more important of which are *Light Science for Leisure Hours* and *The Sun* (1871); *The Orbs around Us* and *Essays on Astronomy* (1872); *The Expanse of Heaven*, *The Moon*, and *The Borderland of Science* (1873); *The Universe and the Coming Transits* and *Transits of Venus* (1874); *Our Place among Infinities* (1875); *Myths and Marvels of Astronomy* (1877); *The Universe of Stars* (1878); *Flowers of the Sky* (1879); *The Poetry of Astronomy* (1880); *Easy Star Lessons* and *Familiar Science Studies* (1882); *Mysteries of Time and Space* and *The Great Pyramid* (1883); *The Universe of Suns* (1884); *The Seasons* (1885); *Other Suns than Ours* and *Half-Hours with the Stars* (1887). In 1881 he founded *Knowledge*, a popular weekly magazine of science (converted into a monthly in 1885), which had a considerable circulation. In it he wrote on a great variety of subjects, including chess and whist. He was also the author of the articles on astronomy in the *American Cyclopædia* and the ninth edition of the *Encyclopædia Britannica*, and was well known as a popular lecturer on astronomy in England, America, and Australia. Elected a fellow of the Royal Astronomical Society in 1866, he became honorary secretary in 1872, and took an active part in its proceedings, contributing no less than eighty-three separate papers to its *Monthly Notices*. Amongst the more important of these are papers dealing with the distribution of stars, star-clusters, and nebulæ, and the construction of the sidereal universe. He made frequent use of accurately drawn charts to support and illustrate his arguments, was an expert in all that related to map-drawing, and published two excellent star-atlases. A chart on an isographic projection, exhibiting all the stars contained in the *Bonn Durchmusterung*, may be specially mentioned, in which, within a circle 11 inches in diameter, are 324,198 minute dots, each representing a star in size and position, designed to show the laws according to which the stars down to the 9–10th magnitude are distributed over the northern heavens. Two papers entitled "Theoretical Considerations respecting the Corona" (*Monthly Notices* of R.A.S. vol. xxxi. pp. 184 and 254) are worthy of note, as are also his early papers on the rotation of Mars, in which, from a discussion of observations from 12th March 1666 to 4th February 1889, including 72,232 rotations of the planet, he deduced the period of its rotation with a probable error of $0^{s}{\cdot}005$. He also contributed several papers dealing with the transits of Venus of 1874 and 1882, in which he vigorously criticized the official arrangements for observing them. His largest and most ambitious work, *Old and New Astronomy*, to which he had devoted his

best energies for several years, was unfortunately left unfinished at his death, but was completed by a friend—A. Cowper Ranyard—and published by Messrs Longmans, Green and Co. in 1892. He died at New York, on his way to England, on 12th September 1888. (A. A. R*.)

Prohibition.—See Liquor Laws.

Prome, a district in the Pegu division of Lower Burma, with an area of 2914 square miles and a population of 368,466 (1891); 365,860 (1901). There were 1848 villages in the district in 1898–99, paying Rs.755,672. The population was made up as follows in 1891:—Buddhists and Jains, 354,650; aborigines, mostly Karens, 8521; Hindus, 2384; Mahommedans, 2283; Christians, 628, of whom 381 were natives.

Of the 1,864,960 acres in the district, 306,149 acres were cultivated in 1898–99, and the rest was made up of forests, 316,697 acres; uncultivable land, 942,604 acres; cultivable land, 278,765 acres; and current fallow, 20,745 acres. The total rainfall, taken at Prome in 1898–99, was 37·83 inches. The highest thermometer reading in May was 104°, and the lowest in December was 53° F. The chief towns in the district are Prome, with a population of 30,022 in 1891; Shwedaung, 12,424; and Paungdè, 10,233. Prome is the terminus of the railway from Rangoon. There is a reformatory school for the province at Paungdè, but it is being converted into a district gaol, and the reformatory is moved to Insein. There were 88 boys at the school in 1898–99. In addition to agricultural work, the boys are taught trades, such as those of tinsmith and carpenter.

Proof-Reading.—Proof-reading as a distinct department in the work of a printing office does not date from the very earliest days of "the art preservative of all arts." The first products of the printing-press show abundant evidences of the non-existence of any one specially charged with the duty of correcting the compositors' mistakes. How much conjectural emendation and consequent controversy would have been avoided if the First Folio Shakespeare had been more typographically correct! Sir Theodore Martin said that the typographical errors alone of that work had been computed to number nearly 20,000, which amounts to 2·25 per cent. of the total number of words in the volume. It was a usual practice in the 17th and 18th centuries for authors to send the proofs of their works round amongst their personal friends for correction; and in the universities and colleges sheets of works passing through the press were frequently hung up in the quadrangles for public inspection and correction. With the growth of printing gradually came a demand for systematic proof-reading, and the leading printers engaged scholars and men of letters to read proofs for them. Among these may be mentioned Cruden, of *Concordance* fame ("Alexander the Corrector"), and William Julius Mickle, poet, and translator of Camoens's *Lusiads*, who was a reader at the Clarendon Press. Goldsmith and Dr Johnson also are credited with having wielded the proof-reader's pen. Times, however, have changed since, as the elder D'Israeli wrote, "it became the glory of the learned to be correctors of the press to eminent printers," and to-day in every printing office the proof-reader is found—an unobtrusive functionary, known to publishers, authors, editors, and journalists, but for the most part unknown to the general reading public; a functionary who yet does useful, often valuable, and always indispensable work. The influence of good proof-reading upon the character of book, newspaper, and general printing is too often underrated. The celebrated old printing offices and the foremost of the modern ones owe their reputation for good workmanship largely to the excellence and thoroughness of the work done in their reading-rooms, for no perfection of paper, ink, machining, or binding can atone for bad or slipshod typography.

The nature of the proof-reader's work, frequently monotonous and uninteresting, will be made clear by what follows. After the compositor (see Typography, in the earlier volumes of this Encyclopædia) has set up by hand or type-setting machine (*q.v.*) the "copy" supplied to him, a slip or page proof is "pulled" and sent with the manuscript to the proof-reader. The manuscript is then read aloud by a reading-boy or copyholder, while the proof-reader carefully follows the text before him letter by letter, marking on the margin of the proof all the misspellings, turned letters, "wrong fonts" (letters differing in size or style of face from those in the immediate context), and other errors, and seeing that the punctuation clearly defines the author's meaning. The reading-boy reads rapidly—indeed, an ordinary listener would imagine it to be impossible for the reader to understand him—and as the reader is obliged to keep pace, he goes through the proof again, without the aid of the boy, in order to mark any errors that may have escaped him in the first rapid reading. The proof, called the "first proof," is then sent to the compositor to be corrected. When this has been done, a further proof is submitted to the reader, who, upon satisfying himself by careful revision that it is free from typographical mistakes, passes it as "clean." If the reader, when dealing with the first proof, notices any slips in grammar or errors of fact on the part of the writer, or is in doubt whether any particular word in the manuscript has been correctly deciphered, he underlines the word or passage, and places "Qy." (query) in the margin. The proof is then despatched to the author or editor. On the return of the proof, after the writer's corrections and alterations have been carried out the type is made up into pages and sheets, and another proof pulled. This passes into the hands of the press reader (as distinguished from the "first-proof reader"), who checks the headlines, page numbers, and sequence of chapters or sections, and observes that the pages are of uniform length and that a sufficient amount of margin is allowed, before finally reading through the text. When the press reader's corrections have been effected, the work is ready for the printing machine or the stereotyping foundry.

The cost of proof-reading may be said to range from about 7½ to 20 per cent. of the cost of composition, varying, of course, with the nature of the work.

Many prominent authors have expressed in warm terms their gratitude to the proof-reader for valuable assistance rendered by apt queries and pertinent suggestions. Two of these expressions of opinion may be given as typical, one from a novelist and one from a poet. Charles Dickens said: "I know from some slight practical experience what the duties of correctors of the press are, and how these duties are usually discharged. And I can testify, and do testify here, that they are not mechanical—that they are not mere matters of manipulation and routine; but that they require from those who perform them much natural intelligence, much superadded cultivation, considerable readiness of reference, quickness of resource, an excellent memory, and a clear understanding. And I most gratefully acknowledge that I have never gone through the sheets of any book I have written without having had presented to me by the corrector of the press something I had overlooked—some slight inconsistency into which I had fallen—some little lapse I had made—in short, without having set down in black and white some unquestionable indication that I had been closely followed in my work by a patient and trained mind, and not merely by a skilful eye. In this declaration I have not the slightest doubt that the great body of my brother and sister writers would, as a plain act of justice, heartily concur." Robert Browning thus corroborated Dickens: "I have had every opportunity of becoming acquainted with, and gratefully acknowledging, the extreme service rendered to me; and, if mine be no exceptional case, the qualifications of readers and correctors are important indeed." P. Larousse spoke of French proof-readers as his "collaborateurs les plus chers," and Hugo referred to them as those "modestes savants" so well able "lustrer les plumes du génie"; while the Académie Française consulted them on points arising in the revision of the Academy's dictionary.

Though much good work is done by readers who have

not been practical printers, yet the technical knowledge gained by working as a compositor is essential to the best proof-reading. The reader must possess a quick eye, alert to note every error or mechanical imperfection in the type, and must scrutinize closely every letter of every word, clause, and sentence, while keeping a grasp of the sense of the matter he is dealing with. The more varied his information and the wider his knowledge, the better. Though his strict duty is merely to see that the author's copy is properly reproduced, he is always glad to give the author the benefit of the experience and knowledge he has acquired, and, as a consequence, he is constantly crossing the line which separates proof-reading from sub-editorial duties. From this last consideration has arisen the plea for the reader, on the daily press especially, being placed under the control of, and made responsible to, the editorial department rather than the head of the composing-room.

Proof-readers, as such, have no trade unions, though many of them in Great Britain retain membership of the unions to which they belonged when working as compositors; and in some states of the American Union the compositors insist upon readers being also members of their society. The oldest organization devoted entirely to the interests of proof-readers is the London Association of Correctors of the Press, founded in 1854. For many years it was restricted to a membership of 150, but since the abolition of this limit the membership has steadily increased, and stood in January 1902 at 500. The chief aim of the association is to give its members information as to vacant situations, so as to keep them in full employment; but it also assists members in distress from its benevolent fund, and provides pensions, as well as a sum of money at death. At the end of 1894, when the association had existed forty years, the total funds amounted only to £65; at the close of 1901 they stood at £811. There is in France the Société des Correcteurs des Imprimeries de Paris. There are also proof-readers' societies in several American cities, many of whose members are women, for in the United States women bulk largely in the rank of proof-readers. There are very few women proof-readers in London. In Edinburgh, however, women form a considerable proportion of the proof-readers. (J. A. BL.; J. R*.)

Propellants.—Explosives are those substances, either solid or liquid, which, upon the application of heat or other cause setting up chemical action in them, are capable of instantaneous or extremely rapid conversion into gases occupying a very great volume as compared with that of the original substance, the gases in addition being highly expanded by the enormous heat resulting from the chemical action accompanying the change of state. Those explosives which are used for the purpose of imparting motion to projectiles of all kinds, whereby they are enabled to travel at great velocity through the air, are termed *propellants*. Any gas subjected to great pressure can by the sudden removal of that pressure be made to act as a propellant. Compressed air has been used in this way as a propellant in the Zalinski dynamite gun. (See AIR-GUN, vol. xxv.) The article on GUNPOWDER in the ninth edition of this work may be consulted for the history of its manufacture.

SMOKELESS PROPELLANTS.

History.—The proportions of the ingredients of the British service gunpowder remained for a very long period unaltered. But the introduction of heavy breech-loading guns necessitated the employment of a very slow-burning explosive; and the manufacture of prismatic powders, consisting of seventy-nine parts saltpetre, eighteen parts charcoal, and three parts sulphur, was begun in England in 1884. Smokeless explosives have now very generally superseded gunpowder for all propulsive purposes. As a result of the new processes, described under the article GUN-COTTON in the ninth edition of this work, it became possible to use gun-cotton as a military explosive; the regulation of its rate of combustion sufficiently to enable it to be employed as a propellant in ordnance and small arms had, however, not been effected. It was not until 1885, when the introduction of small-calibre magazine rifles, rendering absolutely necessary the use of a smokeless powder, was occupying the attention of the principal European Powers, that the problem of using gun-cotton or other forms of nitro-cellulose as a propellant was solved by converting it into a substance devoid of all porosity. This result was attained by subjecting the nitro-cellulose to the action of a suitable solvent, by which it was gelatinized, and after evaporation left as a compact homogeneous non-porous material, capable only of burning from the exterior surface towards the centre. The gelatinized material before the evaporation of the solvent can, while still plastic, be rolled out or pressed into sheets, cords, or other desired form, and when dry be cut up into discs, tablets, cylinders, &c. On these lines many smokeless powders have been produced, and are in general use. They differ in details of manufacture, and frequently contain, besides nitro-cellulose, other explosive or non-explosive ingredients. The first country to adopt a smokeless powder for her magazine rifle was France. The Vieille powder was invented in 1885, and contained probably picric acid as well as gelatinized nitro-cellulose. This powder appears soon to have been replaced by what is known as Poudre B, a gelatinized mixture of two varieties of nitro-cellulose. A further development in the production of smokeless powders for propulsive purposes has been the employment of nitro-glycerine as an essential constituent. This substance had been discovered in the year 1847 by the Italian chemist A. Sobrero at Turin. For many years it remained a laboratory curiosity, and it was not until about the year 1863 that Mr Alfred Nobel, a Swedish engineer, commenced its manufacture on a large scale on the Continent, with a view to using it as a blasting agent. In 1875 Mr Nobel made the discovery that the less highly nitrated form of nitro-cellulose known as soluble nitro-cellulose or collodion cotton had the property, when kneaded with nitro-glycerine under the influence of heat, of absorbing the nitro-glycerine. At the same time it lost its fibrous character and became a stiff gelatinous product, in which the nitro-glycerine largely predominated. This product was patented by Mr Nobel as an explosive under the name of blasting gelatine. In 1886 he made the further discovery that if the proportion of soluble nitro-cellulose were increased until it about equalled the nitro-glycerine, and the materials were incorporated by malaxation, or rolling between hot rollers, a horn-like product suitable for use as a propellant resulted. To this product the name of "Ballistite" was given, and it soon became the Italian service smokeless powder. Although a vast number of explosive substances have been proposed as constituents of smokeless powders, the only ones which are now employed for service propellants and for the most generally used sporting powders are varieties of nitro-cellulose and nitro-glycerine (see ninth edition, GUN-COTTON and NITRO-GLYCERINE).

Classification.—Smokeless propellants, whether for warlike or for sporting purposes, may be broadly classed under two heads as follows:—(1) those which are composed of nitro-cellulose, either soluble or insoluble, or a mixture of the two varieties, with the addition sometimes of small quantities of other explosive and non-explosive substances; (2) those which contain nitro-glycerine in addition to the above ingredients. It would be impossible to give a complete list of the very large number of such explosives proposed, patented, and introduced, and it would be equally impossible to give their exact compositions with certainty, as, in the case of the service powders particularly, the ingredients and their proportions are more or less secret. Belonging to class 1 are the service powders of Austria (small arms), Belgium, Denmark, France (small arms), Germany (small arms), Holland, Norway, Russia, Spain, Sweden, Switzerland, Turkey, and the United States. Belonging to class 2 are the service powders of Austria (ordnance), France (ordnance), Germany (ordnance), Great Britain (small arms and ordnance), Italy (small arms and ordnance), and the United States. The most important varieties of sporting powders are as follows:—*Class* 1. Amberite, Cannonite, E.C., Kynochs, Normal, Plastomenite, Rifleite, Schultze, Troisdorf, Von Forster, Walsrode, and Wetteren. *Class* 2. Amberite, Cordite, and Sporting Ballistite.

Qualities.—The principal qualities which all smokeless powders should as far as possible combine are as follows:—(1) Smokelessness. Smoke is due to the presence of solid products of combustion in a very fine state of division. Substances which on explosion could produce nothing but non-condensible gases would be perfectly smokeless; as, however, the explosion of practically all modern powders gives rise to vapour of water which condenses, they all show a slight amount of smoky vapour varying according to the degree of moisture in the air. This is slightly increased by the products of combustion of the small proportions of organic and inorganic matter, in most cases added as moderants. As a rule the smoke is small and dissipates quickly. (2) Freedom from objectionable products of combustion. The gases given off should not be such as will injuriously affect the firer. Carbonic oxide, a poisonous gas, is produced in considerable quantity by the combustion of most smokeless powders; but as it is a combustible gas, and at the moment of its production highly heated, it takes fire on issuing from the barrel and burns away. Other objectionable gases which it was thought nitro-powders might evolve are nitrogen oxides, but these under the ordinary conditions of firing are not

produced, or if produced are instantly destroyed again by the combined action of the large volume of reducing gases, carbonic oxide and hydrogen, and the high temperature. The tendency of rifle- and gun-barrels to become rusty after firing nitro-powders was at one time ascribed to the presence of nitrogen oxide in the explosive gases, and special oils containing alkali were recommended for cleaning the barrels. It is now understood that this tendency is due to another cause, *i.e.*, to the fact that the very high temperature of the explosive gases affects the surface of the bore and renders it more susceptible to the corroding action of air and moisture. Oiling the barrel after firing with a more viscous lubricant than the oil ordinarily used gets over the difficulty. In the case of heavy guns the quantity of heat evolved has an important bearing on the amount of erosion or wearing away which takes place in the bore. It is greater with smokeless powders than with the old black powders, and greatest in the case of those containing nitro-glycerine. Although these nitro-glycerine powders possess the undoubted advantage that a lesser weight of charge is required for the production of the same velocities with lower chamber pressures, owing to the increased expansion of the gases due to the extra heat, this extra heat appears to increase the amount of erosion, and this has to a certain extent restricted their more general adoption. (3) Stability both chemical and ballistic, under all conditions of climate, storage, and use, is undoubtedly one of the most important properties of any explosive. With black powders there was no question of want of stability so long as they were kept dry. Now that the manufacture and proper purification of nitro bodies are well understood, there is also no difficulty in making those used for smokeless powders very stable, and the experience of some years has proved that these powders can stand severe climatic conditions without showing signs of deterioration, and without their ballistic qualities being impaired. (4) High velocities with moderate pressures. The introduction of magazine rifles and quick-firing guns necessitated not only the employment of a powder producing little if any smoke, but also, to enable them to develop their full effect, one giving much higher velocities than those obtainable with the old black powder, without exceeding the permissible limits of pressure in the bore. These improved ballistics became possible with the new powders owing to a great extent to their colloidal or structureless form. Ignition having taken place on the surface of the flake, cube, or cord, combustion can only proceed by successive layers; with the result that although a much larger total volume of gas, with consequent greater velocity of the projectile, is now developed than formerly, this development of gas takes place gradually during the whole time of the passage of the projectile down the bore, with correspondingly more uniform distribution of pressure. The total propelling force is naturally greater, but as it is more sustained, the maximum pressure is not correspondingly increased. It follows, therefore, that for equal velocities much smaller charges are required than when black powder was used, and the chamber pressures are lower; also that for the same or even lower chamber pressures, higher velocities are obtained. In the old powders complete combustion of the explosive took place before the projectile had time to move far down the bore of the gun; high pressures were in consequence set up in the chamber, necessitating a massive breech. As the development of the gas and therefore of the pressure fell off rapidly, the gun thinned down considerably towards the muzzle, and was comparatively short. For smokeless powders the guns are more uniform in outline, to suit the more uniform distribution of pressure, and they are longer, to enable the full effects to be obtained from the comparatively slow-burning explosive. It is obvious that the property of burning in successive layers affords a ready means of adapting the new explosives to the various calibres of small arms and ordnance for which they are used. By increasing the thickness of the flakes or cubes, or the diameters of the cords or cylinders, the surface of ignition for a given weight is decreased with a corresponding decrease of initial development of gas, and consequently of initial pressure, whereas the time of total combustion is increased. The thicker the flake, cube, or cord, the slower-burning the powder and the larger the gun in which it can be advantageously used. (5) Ease and safety of manufacture. The manufacture of smokeless powders consists in, firstly, the production of the nitro-compounds, and secondly, their treatment with suitable solvents to give them the required colloidal condition. As regards nitro-cellulose, the operations are simple and free from all risks, as throughout the operations the nitro-cellulose is always being dealt with in large volumes of water, in which condition it is quite harmless. The manufacture of nitro-glycerine is one of more difficulty and danger. It is a liquid, very sensitive to friction and percussion, and when acid it has a great tendency to decompose spontaneously if adequate means are not adopted of controlling the temperature while the material is in contact with acids. The precautions to be observed in its manufacture are based on these considerations. In most processes for the production of smokeless powders, the nitro-cellulose has to be dried before further treatment. This operation must be conducted with great care, as dry nitro-celluloses, particularly gun-cotton, are very sensitive to shock of all kinds. When once the solvent is added to the nitro-cellulose, or to the mixture of nitro-cellulose and nitro-glycerine, the danger of accidents is much lessened, and the manufacture of smokeless powders from this point is much safer than that of the old gunpowders. In the latter case there was always present a more or less considerable amount of gunpowder dust which formed a highly explosive mixture with the air, ignitable by the smallest spark, and in its turn exploding the dusty gunpowder in process of manufacture. In the case of smokeless powders there is practically no dust; and the explosives themselves, wetted with the solvent, and more or less gelatinized, would, if ignited, burn away very fiercely but without explosion unless confined; and even if confined, as in the press cylinders, an ignition or explosion would be entirely local, and would not spread to the bulk of the material under treatment.

Most naval and military smokeless powders are in the form of flakes, cubes, cords, ribbons, or cylinders either solid or with one or more perforations; sporting powders are required to be quicker-burning, and are often granular like the old gunpowders, or in the form of very thin flakes. Some cord powders have one or more axial perforations. Flat strips with and without perforations are also made. The colours vary considerably, and depend to a great extent on the added non-explosive ingredients. Pure nitro-cellulose powders are, as a rule, greyish or yellow; those in which nitro-glycerine is present vary in colour from light yellow to deep brown. Sporting powders sometimes contain colouring matters, and are frequently coated with graphite, which gives them a silvery grey appearance. The surface of the flake, cube, and cord powders is usually smooth and hard, and in texture they are horn-like if made from nitro-cellulose, but softer and more of the consistency of india-rubber if containing nitro-glycerine. Their density varies according to the ingredients and method of manufacture. Unless they contain ingredients soluble in water such as metallic nitrates, they are unaffected by damp, and they do not absorb any appreciable amount of moisture. They are more difficult to ignite than black powders, and in the case of small-arm powders require a stronger cap; cannon cartridges require a priming of fine-grain gunpowder or of gun-cotton. Experiments carried out with cordite on several occasions have shown that when packed in the service stout wood boxes with screwed down lids, the boxes may be subjected to a fierce fire which only ignites the cordite without explosion when the flames reach it; and that the cordite in a box may be ignited and burnt away without exploding or even setting fire to boxes packed round it. As far as experiments have hitherto shown, most smokeless powders are fairly insensitive to shock, and are not exploded by the impact or passage through them of rifle bullets even when made up in small-arm cartridges packed in boxes.

Manufacture.—The process of manufacture of both classes of smokeless powders referred to above is similar in all essential particulars, and consists of the three following main operations:—

1. Incorporating and gelatinizing the ingredients either by means of a solvent or by heat.
2. Forming the gelatinized material into the desired shape.
3. Drying or expelling the solvent and any moisture.

The nitro-cellulose, in a very fine state of division, and free from small lumps and knots which would delay the action of the solvent, is thoroughly dried. The gelatinization and the incorporation of the other ingredients are effected almost universally in the kneading machines of Messrs Werner, Pfleiderer and Perkins. This machine is described below under the manufacture of cordite. The usual procedure is to pour in the solvent and start the machine, and then add the nitro-cellulose, or it may be roughly mixed with the solvent before charging into the machine. The other ingredients may be added separately in a fine state of division if solid, usually after incorporation has been proceeding for some little time, or if they are soluble in the solvent they may be added immediately. When nitro-glycerine is an ingredient it is either mixed roughly with the nitro-cellulose by hand before being charged into the machine, or it is mixed with a portion of the solvent and then added. The solvents most generally used are acetic ether or acetone, but when soluble nitro-celluloses only have to be dealt with, an ether-alcohol mixture may be employed. Less used solvents are ether, and the methyl, ethyl, and amyl acetates. The gelatinizing action of the solvent is much assisted by the kneading and squeezing action, and the constant agitation the materials receive in the machine. The time of incorporation varies from about four to eight hours, but it depends on the amount of solvent and to a certain extent on the nature of the other added ingredients. On completion of the gelatinization the mass is of a pasty consistency due to the presence of the solvent, and is in a very suitable condition for rolling out into sheets or pressing through dies to form cords. To form it into sheets, the paste is passed backwards and forwards through hollow chilled cast-iron rollers usually steam heated, their distance apart being capable of adjustment so as to produce any required thickness

of sheet. The sheets are next placed in drying stoves, where the solvent is driven off; and as the drying generally produces blisters and unevennesses in the sheets, they are again passed through hot rollers. The sheets are rolled out very thin in the first instance; to form thicker flakes or cubes they are folded over and over and passed through the rolls between each successive folding until the desired thickness is obtained. This treatment dispels all traces of the solvent, and welds the sheets thoroughly together. The sheets are then cut first of all into strips, and the strips divided into flakes or cubes, for which purposes various machines are in use; or the sheets may be converted into grains much in the style of gunpowder. For the manufacture of cord powders such as cordite, screw or hydraulic presses are employed. They consist of a cylinder for containing the paste, closed at the bottom by a plug having one or more orifices of the required shape. A piston slowly descending into the cylinder forces the paste out through the holes in a continuous cord or cords. The cord is delivered either on a revolving reel or on an endless band on which it can be cut to any desired length. The construction and use of the presses are more fully described below, under the manufacture of cordite. The cords, either on reels or cut to lengths and packed on trays, are dried in stoves at a temperature of about 100° F. (37·5° C.). The drying is effected either by hot air blown into the stove, or by radiation from steam or hot-air pipes. In some drying processes, where the recovery of the solvent is aimed at, the drying chambers are in connexion with vacuum-producing and condensing arrangements. All natures of smokeless powders when thoroughly dry are blended and packed. Another method of granulating powders for sporting guns is, when gelatinization is completed, to add hot water to the mass in the machine and to blow in steam; this treatment has the effect of quickly reducing the paste to a granular condition. The solvent is next evaporated and the water got rid of by pressing, centrifugalling, and drying. The grains are finally sifted to the required sizes.

Cordite.

Cordite is the smokeless powder which has been used by the British service since 1891. It was introduced on the recommendation of a committee presided over by Sir Frederick Abel, who came to the conclusion that an explosive containing a considerable amount of nitro-glycerine offered many advantages over any of the purely nitro-cellulose powders then in existence. Experiments by the committee eventually led to the production of a smokeless powder made from nitro-glycerine and gun-cotton gelatinized by means of a solvent, to which a small proportion of a mineral hydrocarbon was added as a moderant. This explosive is known as "Cordite Mark I," and consists of nitro-glycerine, 58 %; gun-cotton, 37 %; mineral jelly, 5 %.

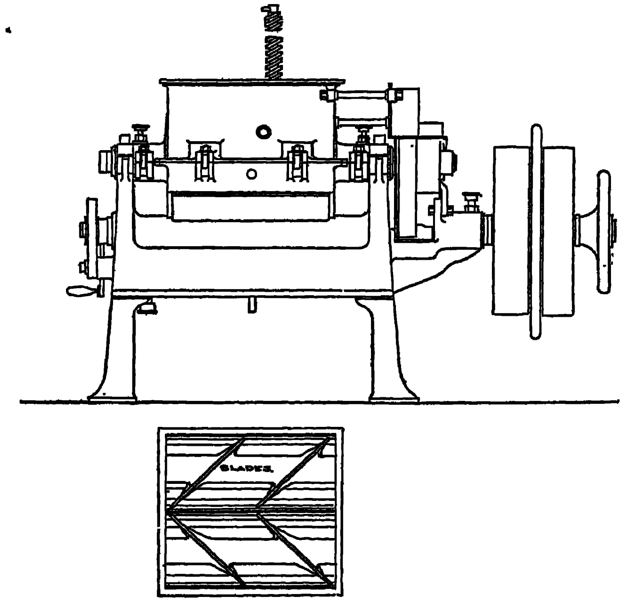
The mineral jelly is a hydrocarbon having the formula $C_{16}H_{24}$, and is obtained by the fractional distillation of crude petroleum oil at a temperature of over 200° C. The variety used for cordite must have a flash point not below 204·4° C. (400° F.), and a melting point not below 30° C. (86° F.). It must also be free from acidity and foreign mineral matters. The solvent used is acetone, C_3H_6O. Acetone is obtained by the destructive distillation of acetates, generally acetate of lime; the principal source of the acetic acid being the destructive distillation of wood. The acetic acid as it distils over from the wood is at once neutralized by lime (or other base) and converted into acetate. The crude acetone as obtained from the acetate, is purified by rectification. It is a colourless aromatic liquid, and as used for the manufacture of cordite it must have a specific gravity of not more than 0·80, must leave no residue on evaporation at 100° C. (212° F.), and must not contain more than 0·005 per cent. of acidity; further, when it is mixed with a 0·1 per cent. solution of potassium permanganate the mixture must retain its pink colour for not less than 30 minutes. The composition of cordite is the same for all descriptions of small arms and ordnance, the required rate of combustion being obtained by varying the diameter of the cords. The density is constant (specific gravity 1·56); it contains practically no moisture, nor is it affected in any way by water. It is poisonous. An exhaustive series of experiments carried out in England, in India, in Canada, and in the Arctic regions, extending over a lengthened period, with the view of testing its keeping qualities, proved that it remained stable in its composition and uniform in its ballistic properties. Experiments also demonstrated its absolute non-sensitiveness to detonation in the form and under the conditions in which it is employed. The different sizes of cordite are designated by a fraction; the numerator gives in hundredths of an inch the nominal diameter of the die through which the cordite is pressed, the denominator, the nominal length of the sticks in inches.

To diminish the erosion produced by cordite of the above composition, especially when firing the heavy charges necessary to produce the high velocities now required from modern ordnance, a modified cordite, known as "Cordite M.D.," is being introduced. Its composition is—nitro-glycerine, 30 %; gun-cotton, 65 %; mineral jelly, 5 %. With Cordite M.D., slightly heavier charges than of Cordite Mark I are required to give the same velocities, but the corresponding pressures are lower, so that by a further increase in the charge, higher velocities can be obtained without exceeding the permissible pressures, and without undue erosion. The manufacture of Cordite M.D. is similar to that of Cordite Mark I.

Manufacture.—The various processes in the manufacture of cordite are as follows:—1. Drying the gun-cotton. 2. Mixing the gun-cotton and nitro-glycerine. 3. Incorporating. 4. Pressing, and reeling or cutting. 5. Drying. 6. Blending and packing.

1. *Drying the gun-cotton.*—The gun-cotton after pulping, is compressed into cylinders 3 inches in diameter and 4½ inches high, of sufficient consistency to enable them to be handled with care. It contains from 40 to 45 per cent. of water. In this form it is placed on trays with copper wire gauze bottoms, arranged on racks in the drying stoves. The drying is effected by means of warm air blown into the stove, the temperature in the stove being kept as nearly as possible at 104° F. (40° C.). The gun-cotton is dried down to under 1 per cent. of moisture.

2. *Mixing the gun-cotton and nitro-glycerine.*—When dry the gun-cotton is weighed out into brass-lined wooden boxes and taken over to the nitro-glycerine final-washing house. The corresponding quantity of nitro-glycerine is weighed out as it comes from the filter tank, and poured over the gun-cotton. The boxes are taken to the mixing house, and the gun-cotton and nitro-glycerine thoroughly



Plan of troughs.

Fig. 1.

mixed by hand so as to break up the gun-cotton and make it absorb the nitro-glycerine. This mixture of gun-cotton and nitro-glycerine is not nearly so sensitive or dangerous to handle and transport as either the dry gun-cotton or the nitro-glycerine alone. The gun-cotton and nitro-glycerine in this roughly mixed condition are known as *cordite paste.*

3. *Incorporating.*—The cordite paste is next taken to the incorporating machines. This machine (Fig. 1) is an iron box, on suitable supports, open at the top, and with a bottom shaped to form two semicircular troughs, in each of which a spindle with screw-shaped blades revolves. The spindles turn in opposite directions, one moving at about twice the rate of the other. They are driven by cog-wheels on a third spindle running underneath the machine. This driving spindle has two pulleys on it, either of which can be put into gear by means of a friction cone. Both pulleys are driven from an overhead shaft, and as one has an open and the other a crossed belt, the blades can be made to revolve inwards or outwards as desired. At the back of the machine is a screw arrangement for tilting it to facilitate the removal of its contents. The lower or trough portion has an iron jacket, through which cold water circulates to keep down the temperature during incorporation. When at work the blades revolve in close proximity to the bottom of the machine, and the paste is continually being squeezed between the blades and the bottom and between the blades themselves as they meet along the centre line. The action is in fact a kneading one, and the machine is very similar to those used for making biscuit dough and for many other like purposes.

The details of the process are shortly as follows:—A portion of the charge of acetone having been poured into the machine, the

blades are started to revolve inwards, that is, towards one another, and the cordite paste ladled in with a wooden scoop, the remainder of the acetone being poured in as the paste is being added. The operation of charging only takes a few minutes, and as soon as it is completed the top of the machine is closed with a wooden cover to prevent the loss of acetone by evaporation, and the machine allowed to run for $2\frac{1}{2}$ hours. At the end of this time the weighed quantity of mineral jelly is added, and the machine set to work for another $2\frac{1}{2}$ hours. For about the last quarter of an hour the motion of the blades is reversed—that is, they are made to revolve away from one another; this has the effect of breaking up the "cordite dough," as it is now termed, in which condition it is more easily filled into the press cylinders. At the end of the five hours the gelatinization of the gun-cotton, and its admixture with the nitro-glycerine by the aid of the common solvent, acetone, is complete, and the mineral jelly is also uniformly distributed throughout the mass. The blades are now stopped, and the cordite dough removed from the machine and placed in barrels for conveyance to the press house.

4. *Pressing.*—There are three kinds of presses in use at Waltham Abbey for pressing cordite, viz., screw, screw and hydraulic combined, and hydraulic. The screw presses are used for the manufacture of small-arm cordite, and are combined with an automatic reeling arrangement for winding the cordite on reels as it issues from the die. The screw and hydraulic combined, and the hydraulic presses, are for producing the large natures of cordite, and are provided with cutting gear for cutting the cordite to the required lengths as it is pressed. The general construction of the screw press for small-arm cordite is shown in Fig. 2. The plunger, the upper portion of which is screwed, passes up through the centre of a worm wheel worked by a worm on a horizontal shaft, to which the driving pulleys are attached. By means of automatic striking gear the motion of the worm is reversed when the plunger comes to the bottom of its stroke, and stopped when the return stroke is completed.

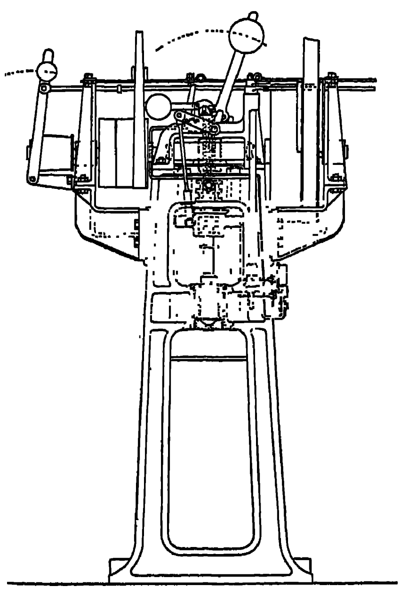


Fig. 2.

The reeling gear is shown in Fig. 3. The reel, the body of which is of sheet brass, with skeleton brass ends, is mounted in front of the press on a horizontal spindle with a cone pulley fixed to one end, and is driven by another cone pulley on the worm shaft; this latter pulley is made to revolve by means of a friction cone worked by a lever on the right side of the machine. The object of the cone pulleys is to enable the speed of the reel to be adjusted to suit the rate at which the cordite is issuing from the die. The cordite is traversed automatically from side to side of the reel as it is wound upon it. The press cylinders are closed at the bottom by a plug, in the centre of which is the die. Resting on the plug is a steel plate with a number of holes in it. This plate supports a fine wire gauze disc, which acts as a sieve to prevent small particles of foreign substances from getting into and blocking up the die. The cylinder is shown in section in Fig. 2. The press cylinders are filled by hand ramming. The full cylinder is placed in the press under the plunger, and the machine started and worked as above described. On completion of the up-stroke, the empty cylinder is removed from the press and another full one inserted. Each cylinder contains a little over one pound of cordite dough. A fresh reel is used for each cylinder, and the reels as filled are taken to the drying-stove.

The screw and hydraulic presses for the large natures of cordite are, as far as the actual pressing is concerned, on practically the same principle as the screw press just described. The press cylinders, however, are an integral part of the machine, and are not removed for filling, the filling being done from a hopper attached to the cylinder, which latter is deep enough to contain the whole charge in an uncompressed condition.

In one pattern of press the plunger screw is attached to and revolves in a ram working in a small hydraulic cylinder. When the press cylinder is charged the valve leading to the hydraulic cylinder is opened, and the pressure, acting on the ram and plunger, forces it down, and it compresses the material into the actual press cylinder. The screw gear is then started and the material pressed out through the die. The arrangement of perforated plate and wire gauze strainer is the same as in the small press cylinder. The number of dies in the plug, that is the number of cords that can be pressed at one time, depends on the diameter of the press cylinder and on the size of the cordite which is being pressed.

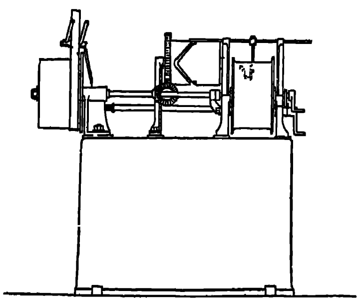

Fig. 3.

The smaller sizes of cordite, sizes $\frac{5}{12}$, $\frac{7\cdot5}{12}$, and $\frac{10}{7}$, are reeled by hand as they issue from the die, on reels of similar materials to those used for small-arm cordite. As soon as a pressing is completed, the reels are taken to a cutting machine, consisting of two horizontal steel blades mounted on a stand opposite one another and in the same plane. The reel is supported in the stand so that the cordite lies at right angles to and between the two blades, which are then brought together, cutting through the cordite and dividing it into a number of strands of equal or nearly equal length, this length being that of the semi-circumference of the reel. The cordite is then laid out flat on shallow wooden trays, the bottoms of which are formed of narrow battens with open spaces between them.

The larger sizes of cordite, viz., $\frac{15}{17}$ and above, are led as they issue from the die on an endless leather band travelling at the same rate as the issuing cordite. This band has steel blades on its surface, fixed at right angles to the direction of its motion. The band passes under a roller, adjusted so as to press the cordite on to the knives, and in this way it is cut to length, the length being regulated by the distance apart of the blades on the belt. As they are cut, the strands are picked off the belt by hand, and arranged on trays, as described above in the case of the smaller sizes.

The hydraulic press is on the usual principle of such presses. The plunger is fixed, and the cylinder is supported on a table which is secured to the ram. As the ram ascends, the cordite is pressed out, and reeled or cut on the endless band; as already described.

5. *Drying.*—All cordite, after pressing, is dried in stoves, heated by means of steam pipes or hot-air blast to a temperature not exceeding 38° C. (100° F.). The reels or trays are arranged on open racks in the centre of the stove. Small-arm cordite takes about three days, the larger sizes about six days, and the largest nearly three weeks to dry. The object of the stoving is to remove the acetone and any moisture from the cordite.

6. *Blending and Packing.*—After drying, small-arm cordite is blended as follows:- Ten single-strand reels are mounted on a frame and wound off simultaneously on a larger reel. The winding is done by a small machine in which the single large reel is made to revolve and draw the cords from the 10 single-strand reels; a lever actuated by cam, through which the ten strands pass, guides them from side to side of the larger reel as they are wound on it. Six of the full 10-strand reels are next taken, mounted on a stand, and the 60 strands wound off on a drum in the same way as the 10 single strands were wound on the 10-strand reel. When the reeling is completed, the ends are all secured by a band of stout tape wound round the drum, and the drum is packed in a box or barrel for transport. Larger sizes of cordite, which have been cut into lengths, are blended as follows:—As the trays come from the stove, their contents are packed into boxes, each containing about 100 ℔ of cordite, until a sufficient number of boxes to form a lot have been filled. This number is subdivided into batches, the number of boxes in a batch varying with the size of cordite, and the cordite in each batch of boxes is blended, by taking a few sticks from each box of the batch and packing them into another set of boxes, filling one box at a time until the whole of the original boxes have been emptied. A box of the blended material is then taken from each batch, and the contents of these boxes are again blended, as above described, so as to form when completed a uniform lot, the number of boxes forming a lot varying with the nature of the cordite. Cordite is packed in wooden boxes holding from 50 to 115 ℔, according to the size of the box and the nature of the cordite.

Cordite for blank ammunition and for Webley pistol cartridges.—Cordite for blank ammunition is prepared from size 20. After the cordite has been dried it is wound on reels. These reels are mounted on a stand in front of a machine which automatically feeds about 40 strands at a time through rows of holes in a fixed plate, in front of which, and close up against it, a disc revolves at a very high rate of speed. Attached to this disc are four knives, set at right angles to one another, which take thin slices off the strands as they are fed through the plate, the principle of the machine much

resembling that of a chaff-cutter. The flakes should vary in thickness between 0″·008 and 0″·003. It is designated $\frac{20}{\text{s.c.}}$.

Cordite for the Webley pistol is prepared by slicing size 1 cordite in a machine similar in principle to the one used for making $\frac{20}{\text{s.c.}}$. It is designated $\cdot\frac{1}{05}$.

Tests.—The tests for finished cordite are as follows :—

1. *Analysis.*—To ascertain that the percentage composition is correct.

2. *Moisture test.*—To ascertain that it does not contain more than a certain percentage of volatile matter varying with the size of the cordite.

3. *Heat test for stability.*—This test is briefly as follows:—20 grains of finely ground cordite are placed in a test tube provided with a stopper, through which passes a glass rod terminating in a hook. A piece of filter paper saturated with a solution of starch and potassium iodide, and dried, is attached to the hook, and the upper half of the paper moistened, when about to be used, with a solution of glycerine in water. The paper is inserted in the test tube, and the test tube placed in a water bath heated to 180° F. The test is completed when the faint brown line, which after a time makes its appearance at the margin between the wet and dry portions of the test paper, equals in depth of tint the brown line drawn on a standard test paper. This test with slight modifications is the one in general use for testing the purity of all nitro-explosives.

4. *Ballistic proof.*—Each size of cordite is fired in the small arm or piece of ordnance with which it is intended to be used, under certain fixed conditions as to weight of charge and projectile, &c., and must give velocities and pressures within certain defined limits.

(F. L. N.)

Prossnitz (Czech, *Prostějov*), chief town of a government district in the fertile plain of Hanna, in Moravia, Austria. It has important textile, malt, and sugar industries, distilling, brewing, and milling, manufactures of agricultural implements and lucifer matches. Geese are bred in large numbers, and there is a brisk trade in corn. Population (1890), 19,512; (1900), 24,054.

Prostitution.—Prostitution may be defined as promiscuous unchastity for gain. In German law it is described as *Gewerbsmässige Unzucht.* It has always been distinguished in law and custom from concubinage, which is an inferior state of marriage, and from adultery and other irregular sexual relations, in which the motive is passion. Prostitution has existed in all civilized countries from the earliest times, and has always been subject to regulation by law or by custom. In Christian countries attempts have repeatedly been made to suppress it, but without success. Its ultimate basis lies in the two most elementary attributes of living things, namely, the will to live and the instinct of reproduction. The one represents the interest of the individual, the other that of the race; and the essential character of prostitution is that it utilizes the latter to satisfy the former, whereas in true sexual passion, as Schopenhauer has pointed out, the advantage of the individual is subordinated to the needs of the race. In practical language, prostitution offers, through abuse of the sexual instinct, a means of livelihood which a certain proportion of women prefer to other means. It is often assumed by philanthropic moralists that no other means are open to them. That may be so in cases in which deception or constraint has been used, and adverse circumstances—such as lack of friends and a harsh social code—close the door to other occupations; but to suppose that such cases account for prostitution is to misapprehend the problem. The detailed investigations of various observers and the experience of rescue societies prove that the great majority of prostitutes prefer that means of livelihood to others entailing regular work, discipline, and self-control. When they really cease to prefer the life, they leave it voluntarily.[1] Otherwise there is extreme difficulty in reclaiming even the few who will consent to try, and permanent success is only attained with a small proportion of them. The earliest attempt at reclamation met with the same result. It was carried out by the Roman Empress Theodora, wife of Justinian, herself a prostitute in early life. She established a home for 500 women on the Bosphorus, but after a time they could not bear the restraint; some threw themselves into the sea, and eventually the scheme was abandoned. The preference is due to several causes, of which indolence is the chief. Prostitutes are drawn mainly from the lower classes: the life offers them an escape from the toil which would otherwise be their lot. Women who present themselves to the police for inscription on the Continent frequently give as their reason for embracing the life, that they do not intend to work any more. Other causes are love of excitement and dislike of restraint. The same qualities make the criminal and the wastrel. In addition, a large proportion have the sexual appetite developed in an abnormal degree. Of 3505 women interrogated by M. Buls in Brussels, 1118 admitted *le goût pour l'homme.* The foregoing are primary causes. External conditions which foster any of these tendencies, or destroy the self-respect and sense of modesty which are their natural antidotes, are secondary causes of prostitution. The more important are: (1) difficulty of finding employment; (2) excessively laborious and ill-paid work; (3) harsh treatment of girls at home; (4) promiscuous and indecent mode of living among the overcrowded poor; (5) the aggregation of people together in large communities and factories, whereby the young are brought into constant contact with demoralized companions; (6) the example of luxury, self-indulgence, and loose manners set by the wealthier classes; (7) demoralizing literature and amusements; (8) the arts of profligate men and their agents. Alcohol is often an aid to prostitution, but it can hardly be called a cause, for the practice flourishes even more in the most abstemious than in the most drunken countries. These observations apply to the West. In Oriental countries girls are commonly born into or brought up to the trade, and in that case have no choice.

Among the ancient nations of the East, with the exception of the Jews, prostitution appears to have been connected with religious worship, and to have been not merely

[1] The number of those who do so is considerable. In Copenhagen from 1871 to 1896 33 per cent. of the registered prostitutes were removed from the register by marriage and by returning to their friends. Many women resort to prostitution occasionally, in alternation with work.

tolerated but encouraged. From the Mosaic ordinances and the narrative of the Old Testament it is clear that the separation of the Jews as the chosen people, and the maintenance of their faith, were always felt by Moses and by the later prophets to be chiefly endangered by the vicious attractions of the religious rites practised around them. The code of sexual morality laid down in the Book of Leviticus is prefaced by the injunction not to do after the doings of the land of Egypt, nor after the doings of the land of Canaan, where all the abominations forbidden to the Jews were practised; and whenever the Israelites lapsed from their faith and "went a-whoring after strange gods," the transgression was always associated with licentious conduct. In Egypt, Phœnicia, Assyria, Chaldea, Canaan, and Persia, the worship of Isis, Moloch, Baal, Astarte, Mylitta, and other deities consisted of the most extravagant sensual orgies, and the temples were merely centres of vice. In Babylon some degree of prostitution appears to have been even compulsory and imposed upon all women in honour of the goddess Mylitta. In India the ancient connexion between religion and prostitution still survives; but that is not the case in China, a most licentious country, and, considering the antiquity of its civilization, and its conservatism, we may perhaps conclude that it formed an exception in this respect among the ancient nations. Among the Jews, who stood apart from the surrounding peoples, the object of the Mosaic law was clearly to preserve the purity of the race and the religion. Prostitution in itself was not forbidden, but it was to be confined to foreign women. Jewish fathers were forbidden to turn their daughters into prostitutes (Lev. xix. 29), and the daughters of Israel were forbidden to become prostitutes (Deut. xxiii. 17), but no penalty was attached to disobedience, except in the case of a priest's daughter, who was to be burnt (Lev. xxi. 9). This distinction is significant of the attitude of Moses, because the heathen "priestesses" were nothing but prostitutes. Similarly, he forbade groves, a common adjunct of heathen temples and a convenient cover for debauchery. Again, his purpose is shown by the severe penalties imposed on adultery (death) and on unchastity in a betrothed damsel (death by stoning), as contrasted with the mild prohibition of prostitution. So long as it did not touch the race or the religion, he tolerated it; and even this degree of disapproval was not maintained, for Jephthah was the son of a harlot (Judg. xi. 1). There is abundant evidence in the Old Testament that prostitution prevailed extensively in Palestine, even in the earlier and more puritan days. The women were forbidden Jerusalem and places of worship; they infested the waysides, and there is some evidence of a distinctive dress or bearing, which was a marked feature of the trade among the Greeks and Romans. In the later period of aggrandizement that increase of licentious indulgence which Moses had foreseen took place, associated with infidelity. The people plunged into debauchery, the invariable sign of national decadence, which has always accompanied over-prosperity and security, and has always heralded national destruction. Before leaving the Jews, it may be noted as an interesting fact that the remarkable series of ordinances laid down by Moses in the interest of public health contains unmistakable recognition of venereal disease and its contagious character (Lev. xv.).

History.

Passing on to the ancient Greeks, we find prostitution treated at Athens on a new principle. The regulations of Solon were designed to preserve public order and decency. He established houses of prostitution (*dicteria*), which were a State monopoly and confined to certain quarters. The *dicteriades* were forbidden the superior parts of the town, and were placed under various disabilities. They were compelled to wear a distinctive dress, and, so far from being connected with religion, they were not allowed to take part in religious services. These laws do not seem to have been carried out at all effectually, and were presently relaxed. After the Persian wars more stringent regulations were again introduced. The *dicteriades* were placed under police control, and were liable to prosecution for various offences, such as ruining youths, committing sacrilege, and treason against the State. It is clear, however, that as time went on the Athenian authorities experienced the difficulties encountered by modern administrations in carrying out State regulation. There were grades of prostitution, socially though not legally recognized, and women of a superior order were too powerful for the law, which failed to maintain the ban against them. The Greek *hetœrœ*, who were prostitutes, not "mistresses," and the most gifted and most brilliant members of their class known to history, wielded great and open influence. The test case of Phryne, in which the stern attitude previously maintained by the Areopagus broke down, established their triumph over the law, deprived virtuous women of their sole advantage, and opened the door to general laxity. In later times any one could set up a *dicterion* on payment of the tax. In other Greek cities extreme licence prevailed. At Corinth, which was famous for sensual practices, a temple, with a huge staff of common prostitutes for attendants, was established in honour of Aphrodite and for the accommodation of the sailors frequenting the port. The worship of this goddess became generally debased into an excuse for sexual excesses.

The Romans united the Jewish pride of race with the Greek regard for public decency, and in addition upheld a standard of austerity all their own. In early days female virtue was highly honoured and strenuously maintained among them, of which the institution of the vestal virgins was a visible sign. Their attitude towards prostitution differed, accordingly, from that of other ancient nations. Among them, alone, it was considered disgraceful to a man to frequent the company of prostitutes; and this traditional standard of social conduct, which markedly distinguished them from the Greeks, retained sufficient force down to the later days of the Republic to furnish Cicero with a weapon of rhetorical attack against his political opponents, whom he denounced as *scortatores*. Prostitution was more severely regulated by them than by any other ancient race. They introduced the system of police registration, which is the leading feature of Continental administration to-day. From the earliest days of the Republic prostitutes were required to register at the ædiles' office, where licences were issued to them on payment of a tax. They were placed under stringent control, had to wear a distinctive dress, dye their hair or wear yellow wigs, and were subject to various civil disabilities; but the severest feature of the system was that, once registered, their names were never erased, and consequently remained for ever under an indelible stain. As in our times, registration became ineffective, and neither law nor tradition could check the demoralizing influence of ease and luxury when once external conquest left the Romans free to devote their energies to the pursuit of pleasure. An attempt was made, by the enactment of severer laws against prostitution, to stem the rising tide of immorality, which threatened to taint the best blood in Rome with the basest elements in the later days of the Republic. Citizens were prohibited from marrying the descendants or relatives of prostitutes, daughters of equestrians were forbidden to become prostitutes, and married women who did so were liable to penalties. More stringent regulations were also imposed on prostitutes themselves, in addition to the old disabilities and police system, which remained in force. If

these laws had any effect at all, it was to promote the general prevalence of immorality; they certainly did not diminish prostitution. The profligacy of imperial Rome has never been surpassed for gross and obscene sensuality.

The greatest change introduced by Christianity with regard to prostitution was the adoption of a more charitable attitude towards these social and legal outcasts. The Roman state tax, which had descended to the emperors and had been further regulated under Caligula, was partly given up in the 4th century by Theodosius, on the representations of Florentius, a wealthy patrician, who offered to make good the loss of revenue out of his own pocket. It was fully and finally abolished by Anastasius I. in the next century, and the old registers were destroyed. Then some of the civil disabilities of prostitutes were removed by Justinian in the 6th century. Gibbon, who never gave credit for a good motive when a base one could be found, attributes Justinian's action solely to his desire to marry Theodora, whose life had been notorious; and no doubt she influenced him in the matter, but it is permissible to assume a good motive. Even Gibbon is constrained to admit her virtue after marriage, and to give her credit for "the most benevolent institution" of Justinian's reign, the rescue home for fallen women in Constantinople, which was at any rate disinterested. Though it did not succeed, it marks a turning-point in the treatment of a class which had never met with public sympathy before. At the same time procuration and connivance were severely punished, which is in keeping with the Christian attitude. The early Christian Church laid great stress on chastity, which probably suggested to its Roman persecutors the horrible punishment of forcibly prostituting Christian maidens. Such malignity enhanced the glory of martyrdom without shaking the constancy of its victims; and the triumph of purity in an age of unbounded licence was conspicuously recognized by Alaric, the Gothic conqueror, who gave strict orders in the sack of Rome that the virtue of Christian women was to be respected. The Church, however, was not severe upon prostitutes, to whom the altar was open upon repentance, and some of the fathers explicitly recognized their trade as a necessary evil. Among them was St Augustine, a man of the world, who saw that its suppression would stimulate more destructive forms of immorality. Gradually charity degenerated into patronage. Rome, conquered spiritually by Christianity and materially by the Northern barbarians, sapped the virtue of both. Before the Middle Ages the institutions and ministers of the Church became a by-word for vice. Charlemagne made an effort to suppress the prevailing disorder, but his private life was licentious, and his capitularies, which ordained the scourging of prostitutes and panders, were not inspired by any regard for morality. A period of reform followed. The rise of chivalry, with its lofty idealization of women, and the wave of Christian fervour connected with the Crusades, inspired a vigorous and high-minded campaign against an all-prevalent evil. The Church became exceedingly active in prevention and rescue work, and was assisted by a devout and zealous laity. Rescue missions were organized, convents were founded everywhere for the reception of penitents, and dowries were subscribed to procure them husbands. Fulke de Neuilly was a conspicuous figure in this work. He held missions, preached, and collected large sums for marriage dowries. Pope Innocent III. (1198–1216) pronounced it a praiseworthy act to marry a prostitute; and Gregory IX., a few years later, wrote to Germany that brothel-keepers were not to prevent prostitutes from attending missions, and that clergy and laity who drew profit from prostitution were banned. "Urge bachelors," he wrote, "to marry repentant girls, or induce the latter to enter the cloister." In spite of such efforts, and of occasional spasms of severity by individual rulers, prostitution flourished everywhere throughout the Middle Ages. It was not merely tolerated, but licensed and regulated by law. In London there was a row of "bordells" (brothels) or "stews" in the Borough near London Bridge. They were originally licensed by the Bishops of Winchester, according to John Noorthouck, and subsequently sanctioned by Parliament. Stow quotes the regulations enacted in the year 1161, during the reign of Henry II. These were rather protective than repressive, as they settled the rent which women had to pay for the rooms, and forbade their compulsory detention. The Act was afterwards confirmed in the reigns of Edward III. and Richard II. In 1383 the bordells belonged to William Walworth, Lord Mayor of London, who farmed them out, probably on behalf of the Corporation, according to Continental analogy. They were closed in 1506, but reopened until 1546, when they were abolished by Henry VIII. In London we get the earliest known regulations directed against the spread of venereal disease. The Act of 1161 forbade the bordell-keepers to have women suffering from the "perilous infirmity of burning"; and by an Order of 1430 they were forbidden to admit men suffering from an *infirmitas nefanda*. Probably it was by virtue of this Order that in 1439 two keepers were condemned to eleven days' imprisonment and banishment from the city. In 1473, again, it is recorded that bawds and strumpets were severely handled by Lord Mayor Hampton. On the Continent much the same state of things prevailed during the same period. Prostitution was both protected and regulated, and in many places it constituted a source of public revenue. In France prostitutes were distinguished by a badge, and forbidden to wear jewels and fine stuffs and to frequent certain parts of the town. Public brothels on a large scale were established at Toulouse, Avignon, and Montpellier. At Toulouse the profits were shared between the city and the university; at Montpellier and Avignon the trade was a municipal monopoly, and farmed out to individuals; at Avignon, where the establishment was kept up during the whole period of the popes' residence, the inmates were subjected to a weekly examination. In 1254 Louis IX. issued an edict exiling prostitutes and brothel-keepers; but it was repealed two years later, though in this and the succeeding century procuration was punished with extreme severity. In some parts of France prostitutes paid a tax to the seigneur. In Germany, according to Fiducin, the public protection of *Lust-Dirnen* was a regular thing in all the large towns during the Middle Ages. "Frauenhäuser," similar to those in London and in France, existed in many places. They are mentioned in Hamburg in 1292; and from later records it appears that they were built by the corporation, which farmed them. So also in Ulm, where special regulations were issued in 1430. We find them existing at Regensburg in 1306, at Zürich in 1314, at Basel in 1356, and Vienna in 1384. According to Henne-am-Rhyn, admission to these houses was forbidden to married men, clergy, and Jews, and on Sundays and saints' days they were closed. The laws of the Emperor Frederick II. in the 13th century contain some curious provisions. Any one convicted of a criminal assault on a prostitute against her will was liable to be beheaded; if she made a false accusation, she was subject to the same penalty. Any one not going to the assistance of a woman calling for help was liable to a heavy fine. In these ordinances the influence of chivalry may be detected. At the same time prostitutes were forbidden to live among respectable women or go to the baths with them. Hospitality to important guests included placing the public Frauenhäuser at their disposal. So King (afterwards Emperor) Sigismund

was treated at Bern in 1414 and at Ulm in 1434, so much to his satisfaction that he publicly complimented his hosts on it. Besides the municipal Frauenhauser, there were "Winkelhäuser," which were regarded as irregular competitors. In 1492 the licensed women of Nuremberg complained to the mayor of this unfair competition, and in 1508 they received his permission to storm the obnoxious Winkelhaus, which they actually did. In Italy and Spain the system appears to have been very much the same. At Bologna prostitutes had to wear a distinctive dress, in Venice they were forbidden to frequent the wine-shop, and in Ravenna they were compelled to leave a neighbourhood on the complaint of other residents. At Naples a Court of Prostitutes was established, having jurisdiction over everything connected with prostitution. It led to great abuses, was reformed in 1589, and abolished about a century later.

Such was the state of things in the Middle Ages. In the 15th and 16th centuries a great change took place. It was due to two very different causes: (1) fear of disease; (2) the Reformation. With regard to the first, there can be little doubt that both the slighter and graver forms of venereal disease existed in very remote times, but until the 15th century they attracted comparatively little attention. The constitutional character of syphilis was certainly not understood,—which is by no means surprising, since its pathology has only been elucidated during the last half century and is still extremely obscure,—but one would still have expected to find more notice taken of it by historical, moral, and medical writers in classical and mediæval times. Nor is it possible to explain their reticence by prudery, in view of the unbounded literary licence permitted in those ages. One can only conclude that the evil was less widely spread or less virulent than it afterwards became. At the end of the 15th century it attracted so much notice that it was supposed to have originated then *de novo*, or to have been brought from the West Indies by Columbus—both untenable hypotheses; and, as usual, each country accused some other of bringing the contagion within its borders. To speculate on the causes of this increased prevalence would be idle; it is enough to note the fact and its consequences. It was immediately followed by the Reformation, and the two together led to a general campaign against the system of licensed prostitution. The last Frauenhaus was closed in Ulm in 1531, in Basel in 1534, and in Nuremberg in 1562. In London, as already noted, the bordells were abolished in 1546. In Paris an ordinance was issued in 1560 prohibiting these establishments, and later all prostitutes were required to leave the city within twenty-four hours. These instances will suffice to show the general character of the movement. Nor were municipal brothels ever tolerated again. It is observed by Henne-am-Rhyn — no friend of toleration — that their suppression was followed by the appearance of the crime of infanticide, by the establishment of hospitals for foundlings and for syphilis. This suggests an indictment against humanity which is hardly justified by the facts. Infanticide was no new thing, and foundling hospitals date from the beginning of the 13th century. Their marked increase and the establishment of syphilitic hospitals came a century later than the Reformation campaign against the Frauenhäuser. The suppression of the latter did not affect the prevalence of prostitution. In the 17th century another spasm of severity occurred. In 1635 an edict was issued in Paris condemning men concerned in the traffic to the galleys for life; women and girls to be whipped, shaved, and banished for life, without formal trial. These ordinances were modified by Louis XIV. in 1684. The Puritan enactments in England were equally savage. Fornication was punishable by three months' imprisonment, followed by bail for good behaviour. Bawds were condemned to be whipped, pilloried, branded, and imprisoned for three years; the punishment for a second offence was death. In Hamburg all brothels were pulled down and the women expelled from the town. If these measures had any effect, it was speedily lost in a greater reaction; but they have some historical interest, as the present system was gradually evolved from them.

It would be tedious and unprofitable to follow all the steps, the shifts and turns of policy, adopted in different countries during the 18th century for the suppression or control of an incurable evil. They involve no new principle, and merely represent phases in the evolution of the more settled and more systematic procedure in force at the present time. Its chief feature, as compared with the past, is the establishment of an organized police force, to which the control of prostitution is entrusted, coupled with a general determination to put the subject out of sight and ignore it as far as possible. The procedure on the continent of Europe is virtually a return to the old Roman system of registration and supervision, except that there is no State tax, and names can be removed from the register. The objects are the same, namely, public order and decency, with one important addition, which has given rise to much controversy. This is the protection of health. From what has gone before, the reader will have gathered that it is not, as frequently supposed, a new thing. Already in the Middle Ages the question occupied the attention of Parliament in England, and a weekly examination of public women by the barber (the surgeon of that time) was instituted at Avignon. The practice was adopted in Spain from about 1500, and later in many other places. But the abolition of licensed brothels, and the consequent growth of private prostitution, rendered it a dead letter. To meet the difficulty, registration was devised. It was first suggested in France in 1765, but was not adopted until 1778. The present regulations in France are based on the ordinances of that year and of 1780, which in their turn were borrowed from those of the 16th and 17th centuries, previously mentioned. The *theory* of the modern attitude towards prostitution is clearly laid down by successive ordinances issued in Berlin. Those of 1700 stated that "this traffic is not permitted, but merely tolerated"; the more precise ones of 1792 pronounced the toleration of prostitution a necessary evil, "to avoid greater disorders which are not to be restrained by any law or authority, and which take their rise from an inextinguishable natural appetite"; and the regulations of 1850 and 1876 are headed "*Polizeiliche Vorschriften zur Sicherung der Gesundheit, der öffentlichen Ordnung und des öffentlichen Anstandes.*" This embraces the whole theory of present administration, and if *Gesundheit* be omitted, is not less applicable to the United Kingdom than to the Continent. The last attempt to suppress prostitution in Germany is worth noting, as it occurred so late as 1845. Registration was stopped and the tolerated houses were closed in Berlin, Halle, and Cologne. The attempt was a complete failure, and it was abandoned in 1851 in favour of the previous system.

We proceed to state the present condition of the law in France, Germany, Austria, and the United Kingdom.

Present laws.

France.—The French criminal law takes no cognizance of prostitution. The subject was omitted from the penal code drawn up by the first Republic, and was never restored, although many attempts were made to introduce legislation, on account of the great disorder which arose. Procuration is to a certain extent a criminal offence. Paragraph 334 of the code for-

bids the exciting, favouring, or facilitating habitually the debauch of girls or boys under twenty-one years of age; the penalty is imprisonment for six months to two years, and a fine of 50 to 500 francs. If the offence is committed by parents, guardians, or other persons in a tutelary position, imprisonment is from .two to five years, and the fine 300 to 1000 francs. The regulation of prostitution rests on the law of 1790, which entrusted the preservation of public tranquillity to the administrative authorities; these are in Paris the prefect of police, and in other communes the mayor. The Parisian regulations have been built up by the decrees of successive prefects. They are based on those of 1778, which fell into abeyance at the Revolution, were reintroduced in 1816, amended in 1823, and made more complete in 1830 and 1841. Those adopted in other towns do not differ in any essential particular. The more important points are: (1) registration of prostitutes, which is either voluntary, or compulsory after repeated arrest; (2) recognized brothels, which are of two classes — *maisons de tolérance* (residential) and *maisons de passe* (houses of call); (3) medical examination, which is weekly at the *maisons de tolérance*, while other registered prostitutes must present themselves fortnightly at the dispensary; (4) hospital treatment of those found diseased; (5) rules with regard to solicitation, the frequenting of public places, &c. A small fee is paid for examination. The penalty for infraction of regulations is imprisonment; offences are divided into two classes: (1) slight, (2) grave, and the term of imprisonment varies accordingly from fourteen days to one year. Names may be erased from the register on the following grounds: (1) marriage, (2) organic disease such as to render the calling impossible, (3) return to relations and proof of good behaviour. The whole procedure appears to rest on grounds of doubtful legality. Prostitution never comes before the courts which alone can try offences and pronounce sentence. The police have no power to do so, yet they both try and sentence these women. That is to say, the whole system depends on their doing, by some verbal quibble, what they have no power to do. The question came before the court of Rheims in 1876, in the case of two women who refused to submit to medical examination, and the judge decided in their favour. He was dismissed in consequence, which does not make the situation more satisfactory.

Germany.—The German law is more explicit and more logical. Prostitution is not forbidden, but by paragraph 361 of the Imperial Code women are liable to arrest for practising prostitution without being under police control, and for contravening regulations after they have been placed under such control. This brings the traffic completely under the police, and gives legal sanction to their regulations. These vary to some extent in different places, but their general tenor is the same. They include compulsory registration and weekly or semi-weekly medical examination, together with rules, for the most part extremely strict, with regard to public demeanour and conditions of life. In Hamburg, for instance, prostitutes are confined to certain streets or houses, forbidden to share lodgings with persons not registered, to have female servants under twenty-five years of age, to keep children after school age, to admit young men under twenty, to make a noise or quarrel, to attract attention in any way, to go out between two and five in summer, to frequent certain parts of the town, or public balls, or superior seats in the theatre, to remain out after 11 p.m. (Regulations of 1886). On proved reclamation, supervision may be relaxed or names struck off the register. Generally, the women are compelled to contribute a fixed sum to a sick fund, for defraying the cost of medical examination; and in some places also to a journey fund, which is applied to sending strangers to their homes. Brothels are absolutely illegal throughout Germany. Paragraph 180 of the Imperial Code (1876) makes *Kuppelei* a penal offence. *Kuppelei* is defined as promoting prostitution, either by procuration or by providing facilities of any kind. There is (1) ordinary *Kuppelei*, or simply assisting prostitution for gain, and (2) aggravated *Kuppelei*, which includes false pretences and procuration by parents, guardians, teachers, &c. The penalty for the former is a short term of imprisonment and police supervision; for the latter, penal servitude up to five years. It is obvious that if this law were strictly enforced, it would amount to suppression, for every householder or houseowner who harboured a prostitute would be liable to prosecution. Its actual interpretation, however, is very elastic. A law passed in Prussia in 1900 has for its object the reclamation of the young. Girls under eighteen may be placed under control until they are twenty-one.

Austria.—The Austrian law goes further than the German, and is still more inconsistent with the existing practice. By paragraph 5 of the Criminal Act of 1885 prostitution is actually forbidden, but permission is given to the police to tolerate it under conditions, and to prescribe regulations according to circumstances. Power to punish is also given to the police. Only certain cases of prostitution are liable to criminal prosecution, namely, when continued after police punishment, with disregard of regulations, when practised by persons suffering from venereal disease, and when accompanied by public scandal. Seduction of the young is punishable by imprisonment, eight days to six months; living on the prostitution of others, by eight days to three months. *Kuppelei* is a penal offence. Simple *Kuppelei* includes (1) harbouring prostitutes for the purpose of pursuing their trade, (2) procuration, (3) having any connexion with the traffic —penalty, three to six months' imprisonment; qualified *Kuppelei* is (1) procuration of innocent persons (equivalent to use of false pretences), (2) procuration by parents, guardians, &c.—penalty, one to five years. The police regulations and procedure are similar to those in Germany, but less strict. In all these countries a special service of police is employed.

Great Britain.—The English law differs markedly from the foregoing. It regards prostitution solely as a public nuisance, and dates from the middle of the 18th century. The principal Act (25 Geo. II.) was passed in 1755, making perpetual a previous Act of 1752. It is entitled "An Act for encouraging prosecutions against persons keeping bawdy-houses," and provides that two ratepayers, on giving notice to a constable, may go with him before a justice and obtain an order for proceeding against the persons in question. A further Act was passed in 1763, fixing the penalties; and a third in 1818 (58 Geo. III.), enabling the overseers of the parish to take the requisite proceedings. Thus machinery was provided for dealing with brothels, but it was left to the public to put it in motion. The Vagrancy Act of 1824 enables the police to proceed against "common prostitutes for behaving in a riotous or indecent manner," and also forbids indecent literature. This was strengthened by a special Act (2 and 3 Vict.), applying to London only, for the prevention of "loitering for the purpose of prostitution or solicitation, to the annoyance of passengers or inhabitants." Other large towns have since obtained private Acts for the same purpose. The penalties are fines and short terms of imprisonment. In 1847 an Act was passed making it an offence for publicans to allow "common prostitutes to assemble and continue" in licensed premises. The Licensing Act of 1872 contains a provision to the same

effect. The previous law for dealing with brothels by indictment was strengthened by the Criminal Law Amendment Act of 1885 (48 and 49 Vict. c. 69), which renders "any person who keeps, manages or acts or assists in the management of a brothel," and any owner or occupier who knowingly permits the same, liable to summary conviction under the Summary Jurisdiction Act; penalties for first offence, a fine up to £20, or imprisonment up to three months, increased for second offence to £40 and four months respectively. The same Act also strengthened the law, which had previously been very weak, for the protection of the young and the prevention of procuration. It makes the procuration or attempted procuration of any girl or woman "to become a common prostitute" a misdemeanour punishable by two years' imprisonment, and places the following offences on the same footing: procuring defilement by threats, fraud, or drugs; compulsory detention for defilement or in a brothel; procuring the defilement of girls under twenty-one; inducing them to leave the kingdom or to leave home and go to a brothel, with intent. The defilement of girls under sixteen and over thirteen years of age is also a misdemeanour, and subject to the same penalty; the defilement of girls under thirteen is felony, punishable by penal servitude from five years up to a life-sentence. Owners or occupiers of premises conniving at these offences are equally liable.

No account of the law in the United Kingdom would be complete without some reference to the partial adoption of the Continental system in 1864–83. In 1864 a Contagious Diseases Prevention Act was passed, providing for the compulsory medical examination of prostitutes, and detention in hospital of those found diseased, in the following garrison towns:—Portsmouth, Plymouth, Woolwich, Chatham, Sheerness, Aldershot, Colchester, Shorncliffe, the Curragh, Cork, and Queenstown. The legal machinery was a justices' order granted on sworn information that the woman named was a common prostitute. "The Act having proved very inefficacious" (Judge Advocate-General in House of Commons, April 1883), it was amended in 1866 and extended to Windsor. Two years later an important memorial was drawn up by the Royal Colleges of Physicians and Surgeons in favour of the Acts and their extended application, and in 1869 they were further amended and applied to Canterbury, Dover, Gravesend, Maidstone, Southampton, and Winchester—eighteen places in all. A popular agitation, based on humanitarian and moral grounds, and continuously carried on against the measure, led to the appointment of a Royal Commission in 1871 and a Select Committee in 1879. The direct evidence was strongly in favour of the Acts, alike with regard to the diminution of disease among the troops in the protected towns, the absence of complaints, and the good effect on public order, to which clergymen and other residents testified. The majority of the Committee reported accordingly after three years' inquiry; but in 1883 the House of Commons passed a resolution, by 182 to 110 votes, condemning the compulsory examination of women. As this would have entailed refusal to vote the money required to carry on the system, it was immediately dropped, and the officers of the metropolitan police to whom its execution had been entrusted were recalled. In 1886 the Acts were repealed.

In *India* the system was introduced for military cantonments in 1865, partially suspended at the end of 1884, and stopped in 1888 on account of the action of the House of Commons. A new Cantonment Act was applied in 1889, and an amending Act in 1893, by which the compulsory or periodical examination of women was prohibited. In consequence of the enormous increase of syphilis which followed, a new Order was made in 1897, which gave power (1) to call on persons suffering from a contagious disease to attend the dispensary, (2) to remove brothels, (3) to prevent the residence or loitering of prostitutes near cantonments.

The foregoing summary of existing laws and regulations sufficiently indicates the present methods of dealing with prostitution. All Western nations broadly follow one or other of the systems described, though the local regulations may vary somewhat in minor details.

Conditions actually existing.

The French system of recognized houses, with registration, *police des mœurs*, &c., obtains in Belgium, Russia, Hungary, Spain, and Portugal; Italy adopted it in 1855, but abandoned it in 1888 for a modified system; in the Dutch towns *maisons de tolérance* are permitted with or without a *service des mœurs*; Norway has abandoned registration, except in Bergen and Trondhjem, but otherwise Scandinavia rather follows the German principle of non-recognition, with more or less vigorous policing; of the Swiss cantons, some have the French, others the German system; while the United States and the British self-governing colonies incline more to the English model of comparative freedom, without a moral police or one possessing arbitrary executive powers independent of the courts of justice. All the systems have their defects; all fail to fulfil their purpose in the great cities. The most modest aim is to preserve public order and propriety. This object is better secured on the Continent than elsewhere, but at the cost of submitting to an arbitrary police rule, intolerable to a free people. There appears to be less prostitution, both visible and actual, in Italy than in other countries. Under the English system the streets can be, and sometimes are, kept orderly in provincial towns by an energetic police; but in London the mass of prostitution is so great that the police seem totally unable to cope with it. Important thoroughfares and centres are frequented by large numbers of prostitutes in broad daylight, and choked by them at night. The law with regard to loitering is a dead letter, for these women do nothing but loiter. Flagrant solicitation is to some extent repressed, but for the most part the police content themselves with preventing positive tumults, and do not always succeed in that. On the other hand, the less obvious but more pernicious nuisance of the brothel prevails to a far greater extent on the Continent.[1] Under the French system it is, of course, encouraged, in preference to "surreptitious" prostitution; but under the German it is forbidden. The facts here afford a proof of the impotence of the law no less striking than the condition of the London streets. By the German and Austrian criminal law, quoted above, brothels are prohibited, yet they abound in both countries. In Austria they are recognized, and perhaps the logic of the law is saved by permissive police clauses. In Germany it is not so. Paragraph 180 absolutely disposes of the question, and in Berlin it is acted on. Elsewhere brothels not only existed, but were recognized by authority for years after the passing of the law against *Kuppelei*. It was not until 1886 and 1889 that they were nominally abolished in Hamburg and Saxony respectively. Yet they still exist in most or all of the large towns, with the knowledge and consent, if not with the permission, of the police. In some they are even authorized. Berlin, which is more severely policed than any town outside Russia, is an exception. There brothels are not openly winked at, but the police have to deal annually with 16,000 or 17,000 charges of *Kuppelei*, and the number remains very con-

[1] Dublin furnishes an exception to the usual practice in the United Kingdom. In that city the police permit open brothels, confined to one street, but carried on more publicly than even in the south of Europe or in Algeria.

stant, from which it may be inferred that the law, even when logically and energetically carried out, is quite ineffective. The Continental system of registration is still more delusive. In Russia, where the authorities have the means of knowing the movements and habits of every individual, it may be possible to compel the registration of the majority of prostitutes, but in other countries it is impossible. The police everywhere complain of the amount of "clandestine" prostitution, which they cannot control, and which tends always to increase, under the system, while the roll of inscribed women dwindles. The numbers alone are sufficient to prove the failure of the procedure; for instance, 311 and 270 in Dresden and Munich respectively (Zehnder, 1891), both capital towns and cities of pleasure containing over 300,000 inhabitants. Cologne, with only half the population, had double the number on the register at the same time. In Paris, which may be called the headquarters of Western vice, the disproportion between registered and clandestine prostitution has reduced the whole system to an absurdity. The number of women on the roll is not a tenth of the estimated number of prostitutes; nor is Berlin, with about 3000 on the register, any better off. In Bordeaux, Brest, Lille, Lyons, and Marseilles the same process is going on (Reuss). It follows that the protection of health, which is the object aimed at by registration, is delusive in an equal degree. There are no means of ascertaining the amount of venereal disease existing in any town or country, except in Norway, and consequently no data for comparing one period or one place with another; but we know that all forms of such disease are still very prevalent in all large Continental towns, in spite of the system. The only exact figures available are the military returns, which are of some value. It is in garrison towns of moderate size that compulsory registration is likely to be most efficiently carried out and to produce the most decided results, because the women with whom soldiers consort are by their character and habits least able to elude the vigilance of the police. The following table gives the proportion of admissions to hospital from all forms of venereal disease in the German, French, Austrian, and British forces since 1876. It may be added that the proportion in the Russian army is almost identical with the French, while the Italian figures are slightly higher than the Austrian. It is therefore unnecessary to give them:—

Admissions per 1000 in European Armies.

Year.	German.	French.	Austrian.	British (Home).	British (India).
1876 . .	28·8	57·0	65·8	146·5	203·5
1877 . .	30·0	57·8	66·9	153·2	224·4
1878 . .	36·0	59·7	75·4	175·5	291·6
1879 . .	38·5	63·7	81·4	179·5	253·3
1880 . .	34·9	65·8	75·7	245·9	249·0
1881 . .	39·2	60·6	79·0	245·5	250·6
1882 . .	41·0	62·0	73·7	246·0	265·5
1883 . .	38·2	58·9	73·3	260·0	271·3
1884 . .	34·5	52·1	73·5	270·7	293·5
1885 . .	32·6	50·7	69·0	275·4	342·6
1886 . .	29·7	49·6	65·8	267·1	385·8
1887 . .	28·6	51·6	64·4	252·9	361·4
1888 . .	26·3	46·7	65·4	224·5	372·2
1889 . .	26·7	45·8	65·3	212·1	481·5
1890 . .	26·7	43·8	65·4	212·4	503·6
1891 . .	27·2	43·7	63·7	197·4	400·7
1892 . .	27·9	44·0	61·6	201·2	409·9
1893 . .	...	42·8	64·5	194·6	466·0
1894 . .	...	40·9	64·8	182·4	511·4
1895 . .	...	...	...	173·8	522·3

The most striking thing in this table is the enormous difference between the Continental and the British figures. To make the comparison more complete, we will add the following, which gives the average admissions per 1000 for the three years 1890–92:—

German.	French.	Russian.	Austrian.	Italian.	U.S.A.	British (Home).	British (India).	Dutch (Indies).
27·2	43·6	43·0	63·5	71·3	77·4	203·6	438·0	455·6

It is clear at once that troops in the East stand upon an entirely different footing from those in the West, the Dutch figures being even higher than the British; we may therefore put them aside for the moment. Comparing the rest, we notice that not only are the British figures enormously higher than the Continental, but the latter also show very large discrepancies; and since all the foreign troops are under the same protective system, we may conclude that other factors must be taken into account. The discipline maintained, the character of the soldiers themselves, and the procedure with regard to admission into hospital, no doubt all affect the returns. Further, a sort of epidemic rise and fall is to be noted. All the returns given in the first table show a simultaneous rise for several years, beginning with 1876; and having reached a maximum, each shows a progressive fall, likewise lasting over several years. This points to another disturbing factor. It is convincingly shown by the figures for the protected districts in the United Kingdom before, during, and after the period of protection. In 1864—that is, just before the first Contagious Diseases Act came into operation—the proportional figure was 260; ten years later it had fallen to 126; but in 1883 it had risen again to 234, in spite of the protection. Then, protection being removed, it rose to 276, but afterwards fell again progressively to 191 in 1895, without any protection. It is therefore evident that in interpreting the statistics allowance must be made for large fluctuations due to causes quite independent of the protective system. The margin of difference, however, between the British and Continental returns is so large that, when all allowances have been made, it is impossible to doubt that a considerable degree of real protection is afforded to soldiers by the system. This conclusion is confirmed by the comparatively high returns for the somewhat exotic army of the United States, and still more by the Indian statistics. They rose gradually, it is true, during the cantonment system, but when that was dropped disease increased with shocking rapidity. Between 1887 and 1895 the admissions for primary syphilis rose from 75·5 to 174·1 per 1000, and those for secondary syphilis from 29·4 to 84·9.

The broad conclusion is that under special conditions, and when rigidly enforced, registration and medical examination do to a considerable extent fulfil the purpose of protecting health. Their failure to do so among the population at large and under the ordinary conditions of life is not surprising when we regard the amount of venereal disease which still occurs even among soldiers protected by the most rigorous measures and under the most favourable conditions.

A general view of the whole subject suggests no pleasant or hopeful conclusions. Prostitution appears to be inseparable from human society in large communities. In different countries and ages it has in turn been patronized and prohibited, ignored and recognized, tolerated and condemned, regulated and let alone, flaunted and concealed. Christianity, the greatest moral force in the history of mankind, has repeatedly and systematically attacked it with a scourge in one hand and balm in the other; but the effect has been trifling or transient. Nor have all the social and administrative resources of modern civilization availed to exercise an effective control. The elementary

laws on which prostitution rests are stronger than the artificial codes imposed by moral teaching, conventional standards, or legislatures; and attempts at repression only lead to a change of form, not of substance. It survives all treatment; and though it may coexist with national vigour, its extravagant development is one of the signs of a rotten and decaying civilization. In Western communities the traffic is not carried on so openly as in the East, nor is it exploited for purposes of public revenue, as among the ancients and in the Middle Ages; a veil of reticence and secrecy, for the most part of a transparently flimsy character, is thrown over it; but whatever is gained in public decency is counterbalanced by other attendant evils. Two, in particular, are fostered by the policing of prostitution. One is the system of blackmail levied by the executive. The scandal has been most notorious in the United States, but it exists everywhere, and is a constant source of profound corruption. The other is the growth of the most degraded class that ever disgraced the name of man—the creatures who live upon the earnings of individual prostitutes, with whom they cohabit. They are called *souteneurs* in France, *louis* in Germany, *cadets* in New York, and by various slang names in Great Britain. They are all criminals. They flourish chiefly on the Continent, where they exist in large and ever-increasing numbers; but they find their way everywhere, and are a dangerous menace to society. They are not altogether new. The Elizabethan drama is full of references to men who took toll of prostitutes in return for protective services in the old days of persecution; but they have been greatly fostered by the modern system, under which women find it necessary or convenient to have the cover of a man, who can pass for a husband and baffle the police. Thus the law is evaded on the one hand by the corruption of those who administer it, and on the other by the appearance of a class of criminal idlers more degraded than any other—both greater evils than the traffic which the law is intended, but fails, to control. There are no data for comparing the extent of profligacy at present existing in Western communities with that in other countries or in former times, but the unmentionable facts which come constantly to the knowledge of the *police des mœurs*, and less frequently to the ear of doctors and lawyers, leave no doubt that in intensity of vice the great centres of modern civilization have nothing whatever to learn from Corinth, imperial Rome, ancient Egypt, or modern China. The classical obscenities dug up and relegated to museums are far surpassed by the photographic abominations prepared to-day in Paris or in Amsterdam. The gross perversion and abuse of the sexual instinct implied by these excesses may be a passing phase, but it is a phase which has always marked the decadence of great nations. It is undoubtedly accompanied by a general tendency towards increase of the volume of prostitution. Improvement in the conditions of life among the poor ought to tend in the opposite direction, by removing one of the most potent causes of the traffic, but it is more than counterbalanced by the rising standard of luxury and comfort which accompanies it, by the aggregation of the people more and more into great cities, and by their craving for amusement. The growth of prostitution has already left its marks on the marriage- and birth-rates of the most highly civilized Western communities.

In 1900 the Prussian Government made an attempt, with the co-operation of the medical corporations, to ascertain the amount of venereal disease prevalent in the kingdom. Circular questions were addressed to all members of the medical profession requesting them to report the number of patients suffering from those disorders in their practice at the date of 1st April. Answers were sent in by 63 per cent., and the aggregate number of patients was 40,902. From this datum it is calculated that the number of persons attacked in the course of a year is at the very least 500,000 in Prussia alone (*vide Hygienische Rundschau*, April 1902).

Protection.—Protectionism includes a system of commercial policy and a body of economic doctrine, which in their modern forms are the outgrowth of the commercial and industrial development of the past century. The common definition of protection as a policy is the attempt to develop a manufacturing industry by a system of discriminating duties upon manufactured goods imported from foreign countries. But this is far too narrow a definition to suit the modern use of the term, though the notion of discriminating tariffs is common and, we may say, basal to all definitions. Protection as a policy includes not only discriminating tariffs, but also a large number of other features supplementary to this fundamental one and designed to emphasize its purpose. Thus a scheme of bounties and premiums, of rebates and drawbacks, is everywhere considered an essential element of the protective system. Nor is it any longer limited to the encouragement of manufactures, but includes as well the protection of agriculture, forestry, mining, fishing, shipping, &c. In short, one cannot give a comprehensive and satisfactory definition of protection to-day without giving it a much wider scope than that of a system of protective duties upon manufacturing industry.

National policy.

Many of its advocates claim, and with some show of reason, that the term protection, as now used to describe the commercial policy of a nation, should be so defined as to include all the means by which a country undertakes to secure through the positive efforts of the Government the complete industrial and commercial development of all its resources and of all its parts. As its object is thus comprehensive, its justification is to be found in a series of arguments based upon political, economic, and social considerations. From this point of view the protective policy embraces not merely the system of discriminating import duties in favour of home products—industrial, agricultural, and mining, with which the policy began in the United States, for example—but also the system of bounties offered for the introduction and establishment of new industries; the policy of restricted immigration of the less desirable classes of labourers, combined with the positive inducements to the skilled labour of other countries to transfer itself to the one in question; the system of discriminating or prohibitive tonnage duties, known as Navigation Acts; the system of developing foreign markets by an active policy directed towards securing advantages for home products in foreign countries. In a word, all those pecuniary or other sacrifices which a country may make in order to develop its material resources and establish, develop, and foster industry and commerce. In this wide sense the comprehensive policy adopted by the United States, for example, includes the making of a careful geological and botanical survey of the whole country in order to discover and open up the vast natural wealth of its domain in its mines, forests, and fields; the establishment of experiment stations to test the usefulness of new crops or means of making old crops more valuable; the stocking of its rivers with fish and the afforesting of its mountains; the introduction of new or more valuable

breeds of live stock; the building of railways and canals, and the offering of inducements to private parties to undertake similar enterprises; the deepening of its rivers and harbours, &c.; and, finally, the development, at public expense, of a scheme of technical and commercial education —lower and higher—adapted to discover and train all the talent in the community available for developing the industry and commerce of the country.

If such an account of the features of a protective policy is objected to on the ground that free trade countries like Great Britain have also adopted some of them, it may be replied, that in so far as they have done so, they have adopted the principle of protection, namely, that Government shall adopt a positive policy looking towards the development, by Government aid if necessary, of new branches of commerce and industry and the firmer establishment of old branches. It may further be pointed out that the countries which have adopted the protective policy most fully—the United States, France, Germany, and Russia—have most consistently followed out the policy here indicated, and in all these countries it has been the so-called protectionist party which has identified itself most fully with the comprehensive policy here suggested.

Economic doctrine.

As a doctrine, protection is the set of principles by which this policy of Government aid to industry is justified, and these principles have been elaborated hand in hand with the development of the so-called protective policy, sometimes outrunning its actual application and advocating its further extension, more often lagging behind and seeking for means of explaining and defending what had already been done. The present development of the system and theory of protection is a result of the growing predominance of capitalism in modern society, combined with the tendency of modern politics towards the organization and development of great national states, with the resulting desire to secure their industrial as well as their political independence. It has been further favoured in certain ways by the fact that the financial needs of modern states require a resort to indirect taxation, thus making it easier for the capitalistic forces to exploit the tax system for their own benefit; while the wars of the 19th century have favoured in many ways the tendency towards the adoption of special means, like high discriminating duties, to accomplish this end. Hand in hand with this has gone a steady tendency to see in the state a powerful means of promoting the development of trade and industry, and a growing disbelief in the more extreme forms of the free trade doctrine, such as the type known as Manchesterism, the theory of the *laissez faire, laissez passer* school of economics and politics.

Protection, both as a doctrine and policy, can be best understood by examining the course of its development in those countries adopting it most consistently. Germany and the United States offer the two most striking examples of great modern nations adopting a system of protection and developing under its influence. They may in a certain sense serve as types of the kind of state which in the 19th century has accepted and defended, in its politics at any rate, the so-called protective system. In both cases the high protective system was associated with the development of nationality, of industry, of capitalism, and of a financial system which favoured the growth of certain elements of the protective policy.

United States.

The protective system in the United States began with the adoption of the Constitution in 1789, and found its first formal defence in the celebrated report of Alexander Hamilton on manufactures. The argument and the movement were largely academic. As there was no strong manufacturing interest in existence, so there was no organized capitalistic effort to secure manipulation of the tariff duties in the interest of special industries. There was general agreement, however, that it would be desirable to develop a manufacturing industry in the colonies if it were practicable. A high degree of natural protection was already afforded by the cost of transportation. It was felt, therefore, that a small duty on manufactures would probably serve the purpose, since the development of the manufactures would favour the production of raw material, which would therefore need no special encouragement. It was also felt that a small duty, continued for a few years, would result in the establishment of the industry on such a firm basis that all duties might be abolished. The introduction of this form of protection, *i.e.*, discriminating duties upon imported goods, was greatly assisted, if not originally caused, by the fact that the new Government needed money, which could most easily be obtained by customs duties. Thus all those parties which were opposed to direct taxes joined their efforts with those interested in securing protective duties, in order to commit the Government to the policy of basing its revenue system on a tariff on imports. To these considerations must be added the further one, that the country had just thrown off political dependence on Europe, and felt that it must now become industrially independent also, if it were to be a great nation. These influences, then, namely, firstly, the desire of the statesmen of the time to create a revenue system for the Federal Government which would make it absolutely independent of the states; secondly, the wish to develop an industry which would serve the needs of the new country while it promoted its complete independence of the Old World, conspired to commit the Federal Government from the beginning to a policy of protection based upon a system of discriminating duties. At the same time a system of discriminating tonnage dues and prohibitory regulations relating to foreign shipping in the coasting trade was adopted to promote and foster the shipping interest.

Industry and commerce began to thrive as never before, largely because of the absolute free trade which the constitution had secured among the states of the Union. The long struggle between France and Great Britain, extending from 1806 to 1812, for the possession of the commerce and the trade of the world, combined with the retaliatory measures of the American Government itself, practically destroyed American commerce for a time, and finally led to the British-American war of 1812, which closed in 1815. The financial system of the Federal Government during this war was based on getting the largest possible returns from the customs, so that the duties were screwed up still higher. The ten years period of non-intercourse, while it had seriously injured American commerce, had fostered the growth of American manufacturing; and when the close of the war of 1812 brought with it an enormous influx of foreign goods, particularly from the plethoric warehouses and factories of England, it looked for a time as though the new American industries were destined to vanish as rapidly as they had grown up. And now for the first time appeared a strong, well-developed, capitalistic party, which was, in spite of some drawbacks, destined to grow until it became one of the most characteristic features of the politics of the republic.

The manufacturers of the country determined the tariff policy of the country, and with few reverses pursued a steadily advancing course of victory down to the close of the 19th century. They secured the maintenance of high duties at the close of the war of 1812, and managed to increase them steadily until the reaction of 1830–33, when they were forced to content themselves with a lower rate, which continued, with a slight interruption in 1842–46, until the outbreak of the Civil War in 1861. This was an

opportunity which they knew how to utilize to the greatest advantage. During the war, when the Government was forced to exploit every possible source of revenue, the protectionist party knew how to turn the necessities of the Government to its advantage. The rate of duties was pressed ever higher; and when the war closed, and the taxes could again be lowered, the protectionist managers knew how to lower or remit altogether the non-protective duties, and thus keep high, and even advance to a still higher point, the duties which protected them from foreign competition.

In the meantime the country was turning from agriculture to manufactures at an unprecedented rate. The manufacturing party was becoming ever stronger and more aggressive. As it had also been the national party, it profited by the enormous development of the nationalist sentiment during and after the war. It now became patriotic to favour the development of a national industry. It was treason to advocate free trade—that had been the policy of the slave-holders' party, and the Slave-Holders' Rebellion, as the Civil War was called, had drawn its strength largely from the free trade sentiment. The policy of the protectionist party had expanded with the growth of the country and the necessity of coming to terms with the antagonistic elements. Thus at first the platform of the protectionists had been one of reasonably low duties on manufactured commodities, low duties on half-manufactured, and no duties at all on raw material. But as the country advanced, and it was seen how the interests of manufacturing had been quickened by the policy of discrimination, those engaged in producing raw materials and half-manufactured commodities demanded that they too should be considered. As this concession had to be made by the manufacturers, they were compelled to justify it by other arguments than those used at first. The infant-industry argument gave place to the proposition, that as long as the prices of raw materials and labour were higher in America than abroad, it would be necessary to maintain countervailing duties at least equal to this difference, in order to protect American industry. One branch after another of manufacturing or agriculture was included and given the benefit of protection. In order to have a satisfactory theoretical basis for such a policy, the theory was advanced that foreign trade was a necessary evil, to be diminished as much as possible. The ideas were advanced and spread throughout the country: that the home market should be reserved for home products; that the labourers should be protected against the influx of foreign cheap labour (Chinese Exclusion Acts; restrictive immigration laws); that prices should be kept high, so as to enable employers to pay high wages; that shipping should be encouraged by subsidies, the sugar industries by bounties; that the nation should become ever more independent of foreign nations for all its industrial products, and capable of holding its own against the world in industry as well as in arms.

The protective party has been the national party during a time when the greatest question before the American people was whether it was to be one nation, or two, or twenty, and it naturally profited by the inevitable victory of nationalism; it has always stood for honest payment of national and state debts, if not in the standard according to which they were contracted, in a still better one, and it has profited naturally by this attitude in a country where the development of trade and industry was rapidly and steadily towards a capitalistic state of society in which such policy is favoured; it has stood for a vigorous and active independence in the field of world politics, and it has naturally profited by this fact in a country which was rapidly forging ahead to take its place among the greatest of existing nations, and with an ever-increasing self-consciousness was ready to assert itself among the nations of the world; it has stood for free labour against slave labour, and consequently profited here again in a country whose greatest conflict turned upon the question whether the system of slave labour should be extended or not; it has stood for high wages for American labourers, and in words at any rate has advocated a policy directed to protecting them against competition with the "pauper labour" of the Old World. It has stood for Government activity in the direction of developing railways and canals; of establishing education upon national lines, making it free, in all grades from the kindergarten to the university, to all citizens of the republic, and it has profited by this association in a country where all influences were telling in favour of this tendency. In short, whatever one may think of the wisdom or folly of trying to develop national industry by a system of discriminating duties, the protective party as such in the United States has been on the progressive side of so many of the deep questions of national importance that it has obtained and kept the allegiance of thousands of men who would have been glad to see a change, or indeed a reversal, in the tariff policy of the party.

Germany.

The history of the tariff policy in Germany has been very similar to that of the United States. Beginning with the establishment of absolute free trade among the various German states in the earlier customs union, it extended this policy, by the establishment of the North German Confederation and the new German Empire, to all the states now included in the federation. The long-wished-for political union meant political independence, and when political independence was once achieved, industrial and commercial independence were next desired. Within the empire itself it was necessary, if the new organization were to be strong and vigorous, that the central government should become independent of the individual states; and this could be best effected by giving it a revenue system based upon import duties, which in the long run has enabled the central government to subsidize the state governments, and thus bring them still further under its influence. To develop this system the political support of some strong party was needed. This party was found in the protectionist elements, which have thus again become the national party in a state which was being rapidly nationalized; the industrial party in a society which was rapidly passing from the agricultural to the industrial condition; the capitalistic party in a society which was rapidly becoming capitalistic in all its tendencies. It stood for industrial and commercial, as well as political, independence of other countries, and thus satisfied the longing for national unity and independence of a people which had suffered for centuries from disunion and dependence.

These two examples may serve to explain how the two most powerful industrial nations next to Great Britain have become and remained highly protectionist in sentiment and in action for the last generation, and how they both opened the 20th century with a more openly declared and a more fully developed system of protection than ever before.

Modern advocates and critics.

Protection as a theory or doctrine is to a certain extent an outgrowth or modification of the old doctrines of mercantilism. In its modern form, however, it dates really from the celebrated Report on Manufactures made by Alexander Hamilton when Secretary of the U.S. Treasury in the year 1791. The views there advanced have been further developed by Friedrich List and Henry C. Carey, and have of late years been carried along somewhat different lines to their logical conclusions by Simon N. Patten and George

Gunton. Starting from an argument in favour of temporary duties on manufactured goods imported from abroad until such time as the infant industry might take firm root, the development proceeded through List, who favoured the maintenance of such duties until the country had passed into the manufacturing stage as a whole, and then through Carey to Patten and Gunton, who maintain that a protective policy, extended to cover agriculture, trade, and mining, should be preserved as the permanent policy of the country until the entire world is one nation, or all nations have reached the same level of political, economic, and social efficiency. The protective policy, which a century ago was to be, in the view of its advocates, temporary and partial, has become to-day, in the arguments of its apologists, permanent and comprehensive. We must content ourselves here with a brief statement of the arguments of the leading and most successful defenders of modern protectionism.

Hamilton.

Alexander Hamilton, at that time Secretary of the Treasury, submitted his celebrated Report on Manufactures to the Congress of the United States on the 5th of December 1791. It is in a certain sense the first formulation of the modern doctrine of protection, and all later developments start from it as a basis. It is a positive argument directed to proving that the existence of manufacturing is necessary to the highest development of a nation, and that it may be wisely promoted by various means, of which the most important is a system of discriminating duties upon foreign imports. Among the objects to be attained by the development of a flourishing manufacturing industry are mentioned:—(1) Independence of foreign nations for military and other essential supplies. (2) A positive augmentation of the produce and revenue of society growing out of (*a*) division of labour, (*b*) extensive use of machinery, (*c*) additional employment to classes of the community not ordinarily engaged in business. (3) An increase in the immigration of skilled labourers from foreign countries. (4) A greater scope for the diversity of talents and dispositions which discriminate men from each other. (5) A more ample and various field for enterprise. (6) In many cases a new, and in all a more certain and steady, demand for the surplus produce of the soil. (7) A more lucrative and prosperous trade than if the country were solely agricultural.

Among the feasible means of promoting the development of such an industry he mentions the following:—(1) Protective duties, or duties on foreign articles which are the rivals of the domestic ones, to be encouraged. (2) Prohibition of rival articles or duties equivalent to prohibition. (3) Prohibition of the exportation of the materials of manufactures. (4) Pecuniary bounties. (5) Premiums. (6) Exemption of the materials of manufactures from duty. (7) Drawbacks of the duties which are imposed on the materials of manufactures. (8) The encouragement of new inventions and discoveries at home, and the introduction into the United States of such as may have been made in other countries; particularly those which relate to machinery. (9) Judicious regulations for the inspection of manufactured commodities. (10) The facilitating of the pecuniary remittances from place to place.

The above suggestions contain the outline of a comprehensive scheme for developing the manufacturing resources of the country, and the United States has subsequently adopted, in one form or another, almost all of these propositions. Hamilton considered that the duties, &c., would not have to be very high nor very long continued in order to accomplish their legitimate ends, after which they would become unnecessary, and would naturally be abolished. He conceded that, generally speaking, import duties were taxes on the consumer, and therefore burdens—but burdens which might well be temporarily borne for the sake of the ultimate advantage arising from cheaper goods and diversified industries. He emphasized also the advantage of a home market for agricultural products, and seemed to think that the United States had to pay the cost of transportation both on the agricultural products it exported and the manufactured goods it imported. This report remained the armoury from which the protectionists drew their weapons of offence and defence for two generations, and it has not yet ceased to be the centre around which the theoretical contest is waged even to-day in Germany and France as well as in the United States.

List.

The next great theorist in this field was the German, Friedrich List, who, while an exile in the United States, became imbued with protectionist ideas, and after doing substantial service for them in the country of his adoption, returned to Germany to do battle for them there. He published his *National System of Political Economy* in Germany in the year 1841. It had great and immediate success, and has exercised a wide influence in Europe on theoretical discussion as well as on practical politics. List, like Hamilton, looked on protection as a temporary system designed to facilitate the passage of a country from an agricultural to a manufacturing state. He accepted free trade as generally and permanently true, but suited for actual adoption only in that cosmopolitan era towards which the world is progressing. But in order to prepare for this cosmopolitan period it is first necessary for each nation to develop its own resources in a complete and harmonious manner. A comprehensive group of national economies is the fundamental condition of a desirable world economy; otherwise there would be a predominance of one or of a few nations, which would of itself constitute an imperfect civilization. Protection is a means of educating a nation, of advancing it from a lower to a higher state. He admits that it may involve a loss, but only in the sense that money expended for an education or an educational system is a loss, or that money spent for seed corn is a loss. To the cosmopolitan system of Adam Smith, List opposes the national system as a preliminary and necessary stage. He favours the imposition of duties as the most efficient means of effecting the protection which he has in mind. Agriculture will be sufficiently protected by the constant demand for its products. The essence of his larger work is contained in a pamphlet published in Philadelphia in 1827, entitled *Outlines of American Political Economy*. It is, in fact, a series of letters advocating the further development of the protective system already adopted in the United States.

Carey: Patten.

The third great name in the history of protection is that of Henry C. Carey, an American, in some ways the most distinguished and most influential of the followers of Hamilton and List. He was at first a strong free trader, then a protectionist who believed in protection as a preparation for free trade, and finally an unconpromising advocate of protection in all circumstances and for all nations. In him and in Simon N. Patten, the last, and in many respects the ablest, of the apologists for protection, we have the theoretical development corresponding to the practical outcome of protection as a comprehensive all-embracing scheme extending protection to all branches of industry alike—agriculture, manufacturing, and mining—and aiming to be permanent in its form and policy. As Patten expresses it: "Protection now changes from a temporary expedient to gain specific ends (such as the establishment of manufactures), to a consistent endeavour to keep society dynamic and progressive. Protection has become part of a fixed

national policy to increase the value of labour with the increase of productive power, and to aid in the spread of knowledge and skill, and in the adjustment of a people to its environment." The object of protection has now become, in the view of the theoretical American protectionist, not an approximation to European industrial conditions, but as great a differentiation from them as possible. Carey's works were translated into the leading European languages, and contributed doubtless to the spread of protectionist ideas, though the extreme form in which his views were expressed, and the rambling illogical method of exposition, repelled many who might otherwise have been attracted by the course of his thought.

Economists of other schools, with the exception of the British, have allowed a relative validity to the doctrines of List; and even among British economists, Mill and some of his disciples have conceded the logical possibility of quickening the development of an industry by import duties in such a way as to result in more good than harm, though they have hardly been willing to acknowledge that it is practically possible. The historical school of political economists have generally admitted the reasonableness of protective policies at certain times and places, though usually finding the justification in political and social considerations rather than in economic.

Protectorates.—"Protectorate," which was a few years ago rarely named in books on international law, is now a common term to describe the relation between two states, one of which exercises control, great or small, direct or indirect, over the other. It is significant of the rare use of the term until recent times, that the word does not occur in Sir G. C. Lewis's book on *The Government of Dependencies.* Yet the relation is very ancient. There have always been states which dominated their neighbours, but which did not think fit to annex them formally. It has always been politic for powerful states to facilitate and hide schemes of aggrandizement under euphemistic expressions; to cloak subjection or dependence by describing it in words inoffensive or strictly applicable to other relations. A common problem has been how to reduce a state to submission or subordination while ostensibly preserving its independence or existence; to obtain power while escaping responsibility and the expenditure attending the establishment of a regular administration. Engelhardt (*Les Protectorats Anciens et Modernes*) and other writers on the subject have collected a large number of instances in antiquity in which a true protectorate existed, even though the name was not used. Thus the Hegemony of Athens as it existed about 467 B.C. was a form of protectorate; though the subject states were termed allies, the so-called "allies" must in all important legal matters resort to Athens (Meyer, *Geschichte der Alterthums*, iii. s. 274).

In dealing with dependent nations Rome used terms which veiled subjection (Gairal, *Les Protectorats Internationaux*, 26). Thus the relationship of subject or dependent cities to the dominant Power was described as that of *clientes* to the *patronus* (Marquardt, *Römische Staatsverwaltung*, 2nd ed., i. 80). Such cities might also be described as *civitates fœderatæ* or *civitates liberæ.* Another expression of the same fact was that certain communities had come under the power of the Roman people; *in deditionem* or *in fidem populi Romani venire* (Marquardt, *Römische Staatsverwaltung*, i. 73, 81). The kingdoms of Numidia, Macedonia, Syria, and Pergamum were examples of protected states, their rulers being termed *inservientes.* The Romans drew a distinction between *fœdera æqua* and *fœdera iniqua.* The latter created a form of protectorate. But the protected state remained free. This is explained in a passage of the Digest, 49. 15. 7: "Liber autem populus est is, qui nullius alterius populi potestati est subjectus, sive is fœderatus est; item sive æquo fœdere in amicitiam venit, sive fœdere comprehensum est, ut is populus alterius populi majestatem comiter conservaret. Hoc enim adjicitur, ut intelligatur alterum populum superiorem esse: non ut intelligatur alterum non esse liberum" (Marquardt, *Römische Staatsverwaltung*, 2nd ed., i. p. 46, and the instances collected by Puffendorf, 8. c. 9. 4).

In mediæval times this relation existed, and the term protection was in use. But the relation of subordination of one state to another was generally expressed in terms of feudal law. One state was deemed the vassal of another; the ruler of one did homage to the ruler of another. In his book *De la République* Bodin treats of *Ceux qui sont en protection* (1. c. 7), or, as the Latin text has it, *de patrocinio et clientela.* In Bodin's view such states retain their sovereignty (1. c. 8). Discussing the question whether a prince who becomes a *cliens* of another loses his *majestas*, he concludes that, unlike the true vassal, the *cliens* is not deprived of sovereignty: "Nihilominus in fœderibus et pacis actionibus, quæ inter principes aut populos societate et amicitia conjunctissimos sanciuntur; eam vim habet, ut nec alter alteri pareat, nec imperet: sed ut alter alterius majestatem observare, sine ulla majestatis minutione teneatur. Itaque jus illud clientelare seu protectionis omnium maximum ac pulcherrimum inter principes censetur" (1. c. 7). Elsewhere Bodin remarks, "le mot de protection est special et n'emporte aucune subjection de celuy qui est en protection." He distinguishes the relation of *seigneur* and vassal from that of *protecteur* and *adherent.* As to whether the protected state or prince is sovereign, he remarks, "je tiens qu'il demoure soverain, et n'est point subject." He makes clear his conception of protection by adding, "l'advoué ou adherant doit estre exempte de la puissance du protecteur s'il contrevient aux traictes de protection. Voila donc la plus grande seureté de la protection, c'est empescher s'il est possible que les protecteurs ne soyent saisis des fortresses," &c. (p. 549, ed. 1580). Sometimes letters of protection were granted by a prince to a weak state; thus Louis XIII. granted in 1641 such letters to the Prince of Monaco (Gairal, 81).

Reverting to the distinction in Roman law, Grotius and Puffendorf, in common with many other writers, treat protection as an instance of unequal treaties; that is, "when either the promises are unequal, or when either of

the parties is obliged to harder conditions" (*De Jure Belli et Pacis*, 1. c. 13. 21; *De Jure Naturæ*, 8. c. 9).

The following are some definitions of "protectorate":—

Definitions of protectorate.

"Principis privilegium, quo ne alicui vis inferatur, cavetur, eumque *in protectionem* suscipit." Ducange: "La situation d'un état à l'egard d'un autre moins puissant auquel il a promis son appui d'une manière permanent" (M. Gairal, 52); a definition applicable only to certain simple forms of this relation. "Pour le protegé, une condition de mi-souveraineté substituée à la pleine independence que comporte le régime de simple protection" (p. 58). "La situation respective de deux états de puissance inégale, dont l'un contracte l'obligation permanente de defendre l'autre, et en outre de le diriger" (p. 62). "Unter einem Protektorat versteht man ein Schutzverhältniss zwischen zwei Staaten des Inhalts, das der eine Staat, der Oberstaat oder schutzherrliche Staat, zum dauernde Schutze des anderen Staates—des Schutzstaates oder Understaates—verpflichtest ist; wofür ihm ein mehr oder weitgehender Einfluss auf die auswärtigen Angelegenheiten desselben und theilweise auch dessen innere Verhältnisse eingeraümt ist" (von Stengel, *Die deutschen Schutzgebiete*, 11). "The mark of a protected state or people, whether civilized or uncivilized, is that it cannot maintain political intercourse with foreign powers except through or by permission of the protecting state" (Hall, *Foreign Jurisdiction of the British Crown*, 218). "A British protectorate is a country which is not within British dominions, but as regards its foreign relations is under the exclusive control of the King, so that its Government cannot hold direct communication with any other foreign Power, nor a foreign Power with that Government" (Jenkyns, *British Rule and Jurisdiction beyond the Seas*, 165).

The term is used very loosely. Often it designates a relation which it is deemed politic to leave indefinite: a state desires to obtain the reality of conquest without the responsibilities attaching thereto. It may mean no more than what it says, "One state agrees to protect or guarantee the safety of another." The term is also employed to describe any relation of a political superior to an inferior state. It is also used as the equivalent of suzerainty. As appears from the article SUZERAINTY, the terms are distinguishable. But both imply a desire to carry out changes without friction and not to break up ancient forms; both proceed on the plan of securing the substance of power while allowing the weaker state a semblance of its old constitution.

Certain protectorates originate in treaties; others have been imposed by force. Some are accompanied by occupation, in which case it is difficult to distinguish them from annexation. Thus the treaty of May 1881, Article 21, between France and Tunis, provides for the occupation of strategical points by the army of the protecting state. The establishment of a protectorate may be akin to a guarantee. Generally, however, the former implies a closer relation than a guarantee; and the two relations may be widely different, as may be seen by comparing treaties of guarantee with the treaty establishing the protectorate of Tunis.

Strictly speaking, a protectorate cannot exist over a domain uninhabited or ruled by no organized state; in such cases the elements of the true protectorates are wanting. But the distinction is not adhered to. The difficulty of defining the relations between the protected and protecting states is greater, because a protectorate may imply a condition of transition: a contractual or limited relation of state to state, more or less rapidly changing into true union.

It has been the policy of the British Government in India to establish on the frontiers, as elsewhere, protectorates. The political advantages of the system are pointed out in Sir A. Lyall's *Rise and Expansion of the British Dominion in India*. It is a system "whereby the great conquering or commercial peoples masked, so to speak, their irresistible advance"; it was much practised by the Romans in Africa and Asia; it has been chiefly applied in modern times in India (p. 326). The Indian states are sometimes described as "Feudatory States," sometimes "Independent and Protected States" (Twiss), sometimes "Mediatized States" (Chesney), sometimes "Half-Sovereign," sometimes as in a position of "subordinate alliance" (Lord Salisbury, *Parliamentary Papers*, 1897 [c. 8700], p. 27). The Interpretation Act, 1889 (52 and 53 Vict. c. 63, c. 18), refers to the Indian native princes as under the "suzerainty" of the British Crown. These states are really *sui generis*, and their precise position can be understood only by a private examination of the treaties affecting them. The following are the chief points as to which Indian states are subject to English law:—(1) the Governor-General is empowered to make laws for servants of the British Government and European and native Indian subjects of his Majesty; (2) British laws are in force in certain parts of the native states, *e.g.*, in cantonments; (3) native princes have adopted certain British laws, *e.g.*, the Indian Penal Code; (4) they have no external relations with foreign states; (5) the king is the donor of honours; (6) Acts of Parliament affect them indirectly by directly affecting the British agent; (7) they receive advice, which may be akin to commands. (See also Ilbert's *Government of India*, 142.)

Indian protectorates.

Among the chief British protectorates are: the African group, consisting of British Central Africa, East Africa, Uganda and Zanzibar, Basutoland, and British Bechuanaland; the Indian group, consisting of the protected chiefs near Aden, and the island of Socotra and Somali; the Malay group, consisting of the Malay States in the Borneo peninsula and in Borneo, the protectorates of North Borneo, Brunei, and Sarawak; the Pacific group, consisting of a few islands, includnig Harvey Islands protectorate and Gilbert Islands. France possesses several protectorates, of which the chief are Tunis, Annam, and Tongking. Her policy appears to be to transform them into French territory. Such change has taken place as to Tahiti and Madagascar, and such in effect is the position of the Indo-China protectorates. The chief German protectorates are South-West Africa, Togoland and Cameroon, German East Africa, Kaiser Wilhelm Island, and Kiaochow.

Existing protectorates.

There are two principal divisions of protectorates; the first being those exercised generally by treaty over civilized countries. Of the first, the chief are: (*a*) that of Cracow, which was recognized by the Treaty of Vienna as a free and independent state, and placed under the protection of Russia. It was incorporated with Austria in 1846. (Calvo, 1. 2. s. 42.) (*b*) Andorra, protected by Spain and France as successor of the Counts de Foix (Freeman's *Historical Geography*, 1.343, 537). (*c*) The Ionian Islands, placed under the protection of Great Britain by the Treaty of Paris of 1815. (*d*) Montenegro, as regulated by the Treaty of Berlin of 1878. (2) The second class of protectorates consists of those exercised by one civilized State over an uncivilized people, sometimes called a "Colonial Protectorate" or "pseudo-protectorate," and usually the preparatory step to annexation. Such protectorates have become common, especially in Africa, since 1878. The second class may be subdivided into two groups: (*a*) protectorates exercised over countries with organized governments and under recognized sovereigns,

such as the Malay States; and (*b*) those exercised over countries possessing no stable or definite governments and rulers. The territories of chartered companies, when not within the dominion of the protecting state, may also for some purposes be regarded as protectorates.

Rights and duties of protecting and protected states.

Attempts have been made to define the reciprocal rights and duties of protecting and protected states. Sometimes the treaty creating the relation defines the obligations. Thus in the treaty with respect to Sarawak the latter is described as an "independent state under the protection of Great Britain." "Such protection shall confer no right on his Majesty's Government to interfere with the internal administration of that state further than is herein provided." The British consular officers are to receive exequaturs in the name of the Government of Sarawak. Foreign relations are to be conducted by that Government, and the raja cannot cede or alienate any part of the territory without the consent of the British Government (Hertslet, 18. 227). In the treaty creating a protectorate over the territories of the king and chief of Opopo (Hertslet, 17. 130) the sovereign undertakes to extend to them, and to the territory under their authority and jurisdiction, his favour and protection. They promise not to enter into "any correspondence, agreement, or treaty with any foreign nation or Power, except with the knowledge and sanction of his Majesty's Government." Some treaties establishing protectorates provide for direct interference with internal affairs; for example, the treaty of 1847 creating a French protectorate over Tahiti, and that of 1883 as to Tunis. Sometimes the *Oberstaat*—to use a convenient expression—is content to insist upon the presence of a resident, who guides the policy of the native ruler. In the case of protectorates over uncivilized countries it is usual to stipulate against alienation of territory without consent of the *Oberstaat.*

Protectorates and international law.

The position of protectorates according to municipal and international law is still undetermined, and there are an old view and also a new view of their nature. The relation may be one of international law, two states having entered into obligations by treaty. Or the relation may be one of public law; one of two states has become subordinate to, and incorporated with, the other. No doubt the general rule is that the protected state does not cease to be a sovereign state, if such was its previous status. Its head is still entitled to all the immunities and dignity of a sovereign ruler. Further, the establishment of a protectorate does not necessarily rescind treaties made between the protected state and other states, at all events when the protectorate is not in reality conquest or cession, or when any modification would be to the injury of third parties (*Parliamentary Papers*, Madagascar, 1897 [c. 8700]; Trione, 187). Nor does the new relation make any change as to the nationality of the subjects of the two states, though by the legislation of some countries facilities are afforded to the subjects of the *Unterstaat* to transfer their allegiance. Nor, speaking generally, does the territory of the protected state become part of the territory of the *Oberstaat;* in this respect it is unlike a colony, which may be regarded as an extension or outlying province of the country. At the same time, the question whether a particular protectorate forms part of the "dominion" or "territory" of the Crown for any purposes or within the meaning of any statute cannot be regarded as wholly free from doubt. In charging the jury in *Reg.* v. *Jameson*, Lord Chief Justice Russell of Killowen directed the jury, with reference to the question whether Pitsani-Pitlogo, situated in the Bechuana Protectorate, formed part of the territory of the Crown, that the circumstance that the latter was described as a "protectorate" was not conclusive that it was not "territory" of the Crown within the meaning of the Foreign Enlistment Act (12 *Times* L.R. 594), and put to the jury the question whether the Queen in fact exercised dominion and sovereignty at Pitsani-Pitlogo; a ruling which has not been generally approved, and which is inconsistent with the practice as to determining such questions. Several writers propose this distinction—the protected country is to be considered a part of the territory as to matters to which sovereignty extends, and as to other matters not. In one view, for the purpose of municipal law, the territory of a protectorate is not, but for the purposes of international law is, within the territory of the protecting state. In another view, such territory is foreign only in the sense that it is not within the purview of the majority of statutes (see Hall's *International Law*, 131, 135, Heilborn, 535; Tupper's *Indian Protectorates*, 336; Laband, 2. s. 70). The older view of the position of a protectorate according to international law is contained in the decision of Dr Lushington in the case of "the Leucade" (8 S.T., N.S. 432), to the effect that, the declaration of war by Great Britain against Russia notwithstanding, the Ionian islands, which were then under the protectorate of Great Britain, remained neutral. The king of Great Britain had the right of declaring peace and war. "Such a right is inseparable from protection." But the Ionian states did not become necessarily enemies of the state with which Great Britain was at war. According to one view, the protected state is implicated in the wars to which the protecting state is a party only when the latter has acquired a right of military occupation over the territory of the former. "Cette solution a été reconnue par la France en 1870, à propos de la guerre contre l'Allemagne pour les îles Taiti alors soumises à notre protectorat; elle s'imposerait pour la Tunisie, l'Annam et Tonkin, et pour le Cambodge, où les traités nous conferent le droit d'occupation militaire" (M. Despagnet). In the event of hostilities between the protecting and protected states, such hostilities would be regarded not as of the nature of an insurrection, but as a regular war (Trione, 149). By the General Act of the Berlin Conference it was agreed that the acquisition of a protectorate should be notified to the signatories to the agreement (Article 34), and it has been the practice to give such notice. It was proposed by some of the Powers represented at the Conference that effective occupation should be a condition to the creation of a protectorate on the coast of Africa. But this was opposed by England, and was not adopted (Laband, ii. 680).

Many writers adhere to the doctrine that there is no impairment of sovereignty of the weaker state by the establishment of a protectorate. They also allege that it is *res inter alios acta.* But the trend of recent policy and purport of much recent legislation are against this view. On the whole, the distinct tendency in recent times, especially as to protectorates over uncivilized countries, is to treat the territory of a protectorate as if it belonged to the protecting state. If France, for example, permitted in Tunis or other protectorates operations which were of an unfriendly character to any Power, say Italy or Germany, the injured Power would no doubt look to France for redress. This view would probably be strongly pressed in the case of protectorates over countries having no well-defined or stable government. The probability is that in such cases governments and courts applying international law would be guided not by technical facts—such, to take the case of British possessions, as the fact that an Order in Council permitted appeals to the Judicial Committee—but would look to the facts of the case.

The tendency is for protecting states to assert jurisdiction over foreigners within the territories of the protected states (Westlake, 187; Ilbert, 434). Mr Hall remarks (*International Law*, p. 131 *n.*) that "all the states represented at the Berlin Conference of 1884–85, with the exception of Great Britain, maintained that the normal jurisdiction of a protectorate includes the right of administering justice over the subjects of other civilized states." The General Act contemplated measures which are scarcely compatible with the exemption of European traders and adventurers from the local civilized jurisdiction. He points out that Great Britain—which until lately took the view that a protected state possesses only delegated powers, and that an Eastern state cannot grant jurisdiction over persons who are neither its own subjects nor subjects of the country to which the powers are delegated—had by the Pacific Order in Council of 1893 and the South African Orders in Council of 1891–94 asserted jurisdiction over natives and foreign subjects. It may be added that "the Orders show a gradual increase of the assumption of internal sovereignty" (Jenkyns, 193).

The fact is that in the case of protectorates over uncivilized or semi-civilized countries a development, more or less rapid, is inevitable: control quickly hardens into conquest, and international law more and more takes note of this fact. The probability is that, in deciding the questions here mooted, regard will be had mainly to the facts of the particular case, and to attribute responsibility to the state which possesses the power of control.

Protestant Episcopal Church.—This is the official title of the religious body which represents in the United States the Anglican Communion (*q.v.*). The numerical strength of this Church has never borne any due proportion to its historic claims. It never has been the official Church of the American people, though of late it has made great strides both in numbers and in the respect and confidence of all sorts and conditions of men. Even in colonial days it numbered among its adherents only a very small minority of the population, while for many years after the American Revolution even its friends hardly dared to hope that it could survive the shock it had received. From the first settlement a large part of the population of the thirteen colonies had been either indifferent to, or openly hostile to, the Anglican Church. The Dutch in New York, the Swedes in Delaware, the Scots and Irish in New Jersey, the Germans in Pennsylvania, and the Huguenots in New York and the Carolinas, felt little interest in what was to them the national Church of a foreign people; while the Quakers in Pennsylvania and the Puritans in New England both feared and hated it. Even in Virginia, where the Church of England was recognized by law as the established Church, and where for a while it had full sway, there soon sprang up an active and rapidly growing minority bitterly opposed to it. The troublous times in England during and after the Puritan Commonwealth drove large numbers of religious dissenters to the shores of Virginia, and they were soon reinforced by men like minded from the other colonies. In Pennsylvania provision had been made by charter that "on the petition of twenty persons a preacher might be sent out by the Bishop of London"; but the attempt to do this in 1694 aroused a violent opposition, and it was some time before the Quakers laid aside their distrust. In New York the regular services of the Church of England were unknown until after the capture of the colony by the British, and for some years they were confined to the little chapel within the fort, where the English chaplain and the Dutch dominie took turns in officiating. It was 1697 before Trinity Church, the first Episcopal parish in New York, was organized. The first rector was William Vesey, a communicant of King's Chapel, Boston, and a recent graduate of Harvard College. He crossed the sea to obtain orders after his election, and was ordained by the Bishop of London in 1697. He continued as rector until his death in 1746. At the beginning of the Revolution, besides Trinity Church, with its two stately chapels, St Paul's and St George's, the Church had gained a strong foothold in Westchester county and on Long Island, and had established a line of churches up the Hudson as far as Albany and Schenectady. In New England the Church met with the most bitter resistance. King's Chapel, Boston, was the first Episcopal church in New England, and was erected in 1688 through the influence of Sir Edmund Andros and by the exercise of his authority as royal governor; but the building was closed for a time almost immediately, and the first rector driven from the country, on the news of the accession of William and Mary. In Connecticut, as in Massachusetts, "the Standing Order," *i.e.*, Congregationalism, was the established religion, and every citizen was compelled to pay taxes for its support. In 1707 the first Episcopal church was begun at Stratford. This was followed in 1722 by an event which, Quincy in his history of Harvard College says, "shook Congregationalism throughout New England like an earthquake, and filled all its friends with terror and apprehension." This was the public announcement that Cutler, "the rector," or president, of Yale College, with the two tutors, Brown and Johnson, had decided to take orders in the English Church. Dr Cutler became the first rector of Christ Church, Boston, and Dr Johnson, after many years of faithful labour in Stratford, became the first president of King's (afterwards Columbia) College, New York. The greatest obstacle, however, to the healthy growth of the Church was the fact that for the first 200 years it was left without a bishop, and dependent for all episcopal service on the bishop of London. No such makeshift as the sending out of commissaries to investigate and enforce discipline could make amends for this vital defect. The American Church owes much to Dr Bray, and still more to the Society for the Propagation of the Gospel, which for nearly a century gave liberally men and money for the work; but had missionary bishops been sent out to enforce discipline, to give wise direction, and, above all, to raise up and commission a native ministry, history would have had a very different story to record. As it was, at the beginning of the American Revolution there are said to have been in the colonies only about 300 churches and 250 clergy of the Church of England.

The Revolution was a terrible blow to this little body of faithful men. Naturally many among them, especially in New York and New England, were opposed to the popular movement; and after the war was over, the bitter prejudices against everything English were arrayed against the Church, which had been known as the English Church. Keen observers like John Adams in Massachusetts and

Chief Justice Marshall in Virginia did not hesitate to describe it as "an exotic" and "too far gone ever to be revived." The first quickening of its life began in Connecticut, where at a meeting of the clergy, held at Woodbury on the feast of the Annunciation 1783, Samuel Seabury was elected first bishop of Connecticut. After trying in vain to obtain orders in England, he was consecrated at Aberdeen, in Scotland, on 14th November 1784. Meanwhile, in the preceding October, a meeting had been held in New York, at which representatives from seven states were present. Among them were the courtly Parker of Massachusetts, the stately Provoost and the gentle Moore from New York, the scholarly Smith from Maryland, and the saintly White from Pennsylvania. The first General Convention was held in Philadelphia in 1785. On 4th February 1787, at Lambeth, William White was consecrated first bishop of Pennsylvania and Samuel Provoost first bishop of New York, by the archbishops of Canterbury and York; and in 1790 James Madison was consecrated in the same place as first bishop of Virginia. The "succession" having been thus secured, two years later Thomas John Claggett was consecrated first bishop of Maryland by bishops Provoost, Seabury, White, and Madison. Through him—in whom the Scottish and English lines are thus united—every American bishop to-day can trace his succession.

For nearly a generation after the Revolution the Church dragged on a feeble and a starveling life. Then came a new race of bishops. The Church ceased to apologize for her existence, and began to assert openly her claims as a true branch of the Catholic Church. Hobart, bishop of New York, 1811–30, was the pioneer in this movement, and to him more than to any other man were due the hopefulness and the vigour of the new life. In 1835 the General Convention declared that the Church was the missionary society, elected Kemper as the first missionary bishop to the North-West, and sent out the first missionaries to foreign lands. To-day the Church, notwithstanding her marvellous growth since 1850, holds a position and an influence immeasurably greater than her numerical strength. This is due largely to the fact that she stands for these five things: historic continuity, liturgical worship, equal rights for clergy and laity, absolute separation of Church and State, and the carrying of religion into the daily life of the people. The liturgy is substantially that of the Church of England, with additions from the liturgy of the Church of Scotland, or changes suggested by the test of experience. From 1880 to 1892 a work of liturgical revision was carried on by the General Convention with two objects in view, "liturgical enrichment and increased flexibility of use." The American Church, both in its diocesan and in its general conventions, has recognized fully the right of both clergy and laity not only to legislate about temporal matters, but also to settle questions touching the faith and worship of the Church. Her early experience in colonial days helped the Church to realize the advantage of a separation from the State; yet it was long before the older traditions were laid aside. It was not until 1838 that permission was given to divide a state so as to provide for an additional diocese—and it was not until 1898 that the General Convention abandoned civil lines in arranging and distributing its missionary jurisdictions. It had already refused to accept Government aid for its work among the Indians. Since 1850 the growth of this Church has been especially marked in the older states and the larger cities; but throughout the whole country she has more than kept pace with the increase in the population, so that while in 1850 she had one communicant in every 300 of the population, she had in 1900, roughly speaking, one in every 100.

	Population.	Communicants.
1850 . . .	23,347,884	79,987
1860 . . .	31,442,960	146,600
1870 . . .	38,555,983	220,000
1880 . . .	50,152,866	344,789
1890 . . .	62,480,540	509,149
1900 . . .	76,295,220	700,458

This numerical increase represents very inadequately the real change in her position. The years since 1880 have been marked also by great changes within the Church, in her methods of work, and in the multiplication and enrichment of her services; but the greatest of all has been the dying out of the old party spirit, the broadening and deepening of every school of thought, and the coming together of men of many minds to work for great common ends. Side by side with this, and partly as a result of it, has been the upbuilding of the great city parish. Instead of an unwise multiplication of new parishes, there has been seen a judicious strengthening of the old. Nowhere has this been more marked than in New York City. In 1875 there were only five parishes in the old city of New York claiming each over 600 communicants; now there are nearly a score, reporting each over 1000 communicants, while old Trinity has over 7000, and St George's nearly 5000. The organization of the Church covers now every state and territory within the United States, while her missionary work extends to Africa, China, and Japan, and she is lending a helping hand in Porto Rico, Cuba, the Philippines, Mexico, and Brazil. In every organized diocese there is an annual convention or council, presided over by the bishop and composed of the clergy and lay delegates from the various parishes, and having power to legislate on all local matters. Once in three years the General Convention meets as the supreme legislative body. This is composed of two houses, the House of Bishops, in which each bishop has a seat, and the House of Clerical and Lay Deputies, in which each diocese is represented by four clerical and four lay deputies.

The following table will give some idea of the present condition of the Church and its growth since 1880:—

	Diocese and Missionary Jurisdiction.	Bishops.	Clergy.	Parished Missions.	Baptisms.	Confirmations.	Communicants.	Contributions.
1880	61	61	3435	4151	47,063	25,903	345,841	$7,013,782
1890	67	72	4058	5118	59,902	38,958	470,076	11,183,697
1900	80	84	4878	6519	59,908	43,059	700,458	13,878,380

(H. C. P.)

Protoplasm.—The importance of protoplasm, as the physical and material basis of life, has caused it to be the subject in recent years of much minute and laborious research. Mysterious indeed are the powers and activities manifested by the minute speck of matter which circulates within a plant-cell or creeps freely about as an Amœba, or the "microcosmic subtlety" whereby the tiny spermatozoon transmits to the next generation the qualities and peculiarities which go to make up a human personality. It seems obvious that matter so peculiarly endowed must possess a complexity of structure and organization far exceeding that which at first sight meets the eye. Some biologists have attacked the problem of the ultimate constitution of protoplasm from a purely theoretical standpoint, and have framed hypotheses of an ultramicroscopic constitution sufficient, in their opinion, to explain, or at least to throw light upon, the vital activities of the living substance. Others, proceeding by more empirical methods,

have attempted to lay bare the structure of protoplasm by means of the refinements of modern microscopical technique, or to solve the question of its constitution by means of chemical and physiological investigation. Hence a convenient distinction, not always easy, however, to maintain in practice, is drawn between *speculative* and *empirical* theories of protoplasm.

(1) *Speculative theories* have come with the greatest frequency from those who have attempted to find a material explanation for the phenomena of heredity (*q.v.*). As instances may be mentioned more particularly the "gemmules" of Darwin, the "pangenes" of de Vries, the "plastidules" of Haeckel, and the "biophores" of Weismann. These theories have been ably brought together and discussed by Delage, who has included them all under the term "micromerism," since they agree in the assumption that the living substance contains, or consists of, a vast number of excessively minute particles—*i.e.*, aggregates or combinations of molecules, which give to the protoplasm its specific properties and tendencies ("idioplasm" of Nägeli). In other cases the assumption of invisible protoplasmic units has been inspired by a desire either to explain the general vital and assimilative powers of protoplasm, as, for example, the "micellæ" of Nägeli and the "plasomes" of Wiesner, or to elucidate the mechanism of some one function, such as the "inotagmas" of Engelmann, assumed to be the agents of contractility. In general, it may be said of all these speculations, either that they can only be extended to all vital phenomena by the help of so many subordinate hypotheses and assumptions that they become unworkable and unintelligible, or that they only carry the difficulties a step farther back, and really explain nothing. Thus it is postulated for Wiesner's hypothetical plasomes that they possess the power of assimilation, growth, and reproduction by division; in other words, that they are endowed with just those properties which constitute the unexplained mystery of living matter.

(2) *Empirical theories of protoplasm* differ according as their authors seek to find one universal type of structure or constitution common to all conditions or differentiations of the living substance, or, on the contrary, are of opinion that it may vary fundamentally in different places or at different times. From these two points of view protoplasm may be regarded either as *monomorphic* or *polymorphic* (Fischer). The microscopical investigation of protoplasm reveals at the first glance a viscid, slimy, or mucilaginous substance, in which is embedded an immense number of granules, for the most part very tiny. Very rarely are these granules absent, and then only from a portion of the protoplasm, and only temporarily. Hence many authorities have regarded the minute granules—the "microsomes" of Hanstein—as themselves the ultimate living units of protoplasm, in opposition to those who would regard them merely as "metaplastic" substances, *i.e.*, as the heterogeneous by-products of metabolism and vital activity. The *granular theory*, as this conception of the living substance is called, has received its extreme elaboration at the hands of Altmann, whose standpoint may be taken as typical of this class of theories. After demonstrating the universal occurrence of granules in protoplasm, Altmann has compared each individual granule to a free-living bacterium, and thus regards a cell as a colony of minute organisms, namely, the granules or *bioblasts*, as he has termed them, living embedded in a common matrix, like a zooglœa colony of bacteria. Of this theory it may be remarked, firstly, that it brings us no nearer to an explanation of vital phenomena than do the plasomes of Wiesner; secondly, that to consider bacteria as equivalent, not to cells, but to cell granules, is to assume for this class of organisms a position with regard to the cell theory which is, to say the least, doubtful; and, thirdly, that the observations of the vast majority of competent microscopists furnish abundant support for the statement that granules of protoplasm do not lie free in a structureless matrix, but are embedded in the substance of a minute and delicate framework or *morphoplasm*, which in its turn is bathed by a watery fluid or *enchylema* permeating the whole substance. The upholders of the granular theory deny the existence of the framework, or explain it as due to an arrangement of the granules, or as an optical effect produced by the matrix between the granules. Amongst those, on the other hand, who assert the existence of a framework distinct from granules and enchylema, the utmost diversity of opinion prevails with regard to the true structural relations of these three parts and the rôle played by each in the exercise of vital functions. Some have regarded the framework as made up of a tangle of separate fibrillæ (*filar theory*)—a view more especially connected with the name of Flemming—but most are agreed that it represents the appearance of a *reticulum* or network with excessively fine meshes, usually from ½ to 1 μ in diameter. The reticulum carries the granules at its nodal points, and is bathed everywhere by the enchylema. Even with so much in common, however, opinions are still greatly at variance. In the first place, the majority of observers interpret the reticulum as the expression of an actual spongy framework, a network of minute fibrillæ ramifying in all planes. While, however, Heitzmann, following the speculations of Brücke, considered the framework itself to be actively contractile, and the seat of all protoplasmic movement, an opposite point of view is represented by the writings of Leydig, Schäfer, and others, who regard the reticulum merely as a kind of supporting framework or *spongioplasm*, in which is lodged the enchylema or *hyaloplasm*, considered to be itself the primary motile and living substance. Bütschli, on the other hand, has pointed out the grave difficulties that attend the interpretation of the reticulum as a fibrillar framework, in view of the distinctly fluid consistence of, at any rate, most samples of protoplasm. For if the substance of the framework be assumed to be of a firm, solid nature, then the protoplasm as a whole could not behave as a fluid, any more than could a sponge soaked in water. On the other hand, the hypothesis of a fluid fibrillar framework leads to a physical impossibility, since one liquid cannot be permanently suspended in another in the form of a network. Bütschli therefore interprets the universally present reticulum as a meshwork of minute lamellæ, forming a honeycombed or *alveolar* structure, similar to the arrangement of fluid lamellæ in a fine foam or lather, in which the interstices are filled not with air but with another fluid; in other words, the structure of protoplasm is that of an exceedingly fine emulsion of two liquids not miscible with one another.

It may be claimed for the *alveolar theory* of Bütschli that it throws light upon many known facts relating to protoplasm. It interprets the reticulum as the optical section of a minute foam-like structure, and permits the formation of protoplasmic striations and of apparent fibrillæ as the result of linear or radiating dispositions of the alveolar framework; it reconciles with the laws of physics the combination of a framework with a fluid or semifluid aggregate condition, while variations in the fluidity of the framework are compatible with a stiffening of the protoplasm almost to the pitch of rigidity, as seen, for example, in nervous tissue; and, finally, it explains many characteristic structural peculiarities of protoplasm, such as the superficial layer of radiately arranged alveoli, the spherical form of vacuoles, the continuous wall or pellicle which limits both the vacuoles and the protoplasm as a whole, and many other points not intelligible on the theory of a sponge-like structure. Bütschli has succeeded, moreover, in producing artificial foams of minute structure, which not only mimic the appearance of protoplasm, but can be made to exhibit streaming and amœboid movements very similar to those of simple protoplasmic organisms. Incidentally these experiments have shown that many of the

apparent granulations and "microsomes" are an optical effect produced by the nodes of the minute framework. In his most recent works Bütschli has extended his theory of alveolar structure to many other substances, and has tried to prove that it is a universal characteristic of colloid bodies, a view strongly combated, however, by Fischer. While it cannot be claimed that Bütschli's theory furnishes in any way a complete explanation of life, leaving untouched, as it does, the fundamental question of assimilation and metabolism, he at least draws attention to a very important class of facts, which, if demonstrated to be of universal occurrence, must be reckoned with in future treatment of the protoplasm question, and would form an indispensable preliminary to all speculations upon the mechanism of the living substance.

In opposition to the above-mentioned monomorphic theories of protoplasm, all of which agree in assuming the existence of some fundamental type of structure in all living substance, attempts have been made at various times to show that the structural appearances seen in protoplasm are in reality artificial products, due to precipitation or coagulation caused by reagents used in the study or preparation of living objects. These views have been developed by Fischer, who by experimenting upon various proteids with histological fixatives, has shown that it is possible to produce in them a granular, reticular, or alveolar structure, according to treatment, and, further, that granules so produced may be differentially stained according to their size and absorptive powers. Fischer therefore suggests that many structural appearances seen in protoplasm may be purely artificial, but does not extend this view to all such structures, which would indeed be impossible, in view of the frequency with which reticular or alveolar structures have been observed during life. He suggests, however, that such structures may be temporary results of *vital precipitation* of proteids within the organism, and that protoplasm may have at different times a granular, reticular, or alveolar structure, or may be homogeneous. Fischer's conception of living protoplasm is therefore that of a polymorphic substance, and a similar view is held at the present time by Flemming, Wilson, and others. Strassburger also regards protoplasm as composed of two portions: a motile *kinoplasm* which is fibrillar, and a nutritive *trophoplasm* which is alveolar, in structure.

The chemical investigation of protoplasm labours at the outset under the disadvantage that it cannot deal with the living substance as a whole, since no analysis can be performed upon it without destroying the life. Protoplasm consists, to the extent of about 60 per cent. of its total mass, of a mixture of various *nucleo-proteids*—that is to say, of those substances which, in molecular structure and chemical composition, are the most complex bodies known. In association with them are always found varying amounts of fats, carbohydrates, and other bodies, and such compounds are always present in the living substance to a greater or less degree as products of both upward and downward metabolism. Protoplasm also contains a large but variable percentage of water, the amount of which present in any given case affects largely its fluid or viscid aggregate condition. Especial interest attaches to the remarkable class of bodies known as ferments or *enzymes*, which when prepared and isolated from the living body are capable of effecting in other substances chemical changes of a kind regarded as specifically vital. It is from their study, and from that of the complex proteids found in the living body, that the greatest advances towards an explanation of the properties of living matter may be expected at the present time. (See article PHYSIOLOGY; also Buchner, "Alcoholic Fermentation without Yeast Cells," *Ber. d. deutsch. chem. Ges.* vol. xxx., xxxi., and xxxii.; Verworn, *General Physiology*, London, 1891, p. 304; Reynolds Green, *The Soluble Ferments and Fermentation*, Cambridge, 1899.)

The question may be raised how far it is probable that there is one universal living substance, which could conceivably be isolated or prepared in a pure state, and which would then exhibit the phenomena characteristic of vital activity. It is sufficiently obvious, in the first place, that protoplasm, as we know it, exhibits infinite diversity of character, and that no two samples of protoplasm are absolutely similar in all respects. Chemical differences must be assumed to exist not only between the vital fabrics of allied species of organisms, but even between those of individuals of the same species. Kassowitz regards this variability as compatible with the assumption of a gigantic protoplasmic molecule in which endless variations arise by changes in the combinations of a vast number of atoms and atom complexes. It is difficult to conceive, however, of any single substance, however complex in its chemical constitution, which could perform all the functions of life. To postulate a universal living substance is to proceed along a path which leads inevitably to the assumption of biophores, plastidules, or other similar units, since the ultimate living particles must then be imagined as endowed at the outset with many, if not all, of the fundamental properties and characteristic actions of living bodies. Such a conception has as its logical result a vitalistic standpoint, which may or may not embody the correct mental attitude with regard to the study of life, but which at any rate tends to check any further advance towards an explanation or analysis of elementary vital phenomena. We may rather, with Kölliker, Verworn, and others, ascribe the activities of protoplasm to the mutual interaction of many substances, no single one of which can be considered as living in itself, but only in so far as it forms an indispensable constituent of a living body. From this point of view life is to be regarded, not as the property of a single and definite substance, but as the expression of the ever-changing relations existing between the many substances which make up the complex and variable congeries known to us as protoplasm.

Provençal Literature (Modern: 1350–1900).[1] Literature in the South of France never died out entirely. Indeed, we have a link which, though too much importance may easily be attached to it, yet undoubtedly connects the products of the troubadours with the Provençal poetry of the present day. The Academy of Toulouse, founded in 1324, was flourishing in the 14th century, and, after many vicissitudes, is flourishing still. [The poets crowned by this body between 1324 and 1498 stand in the same relation to the troubadours as the *Meistersinger* do to the *Minnesinger*: academic correctness takes the place of inspiration. The institution flourished, even to the extent of establishing branches in Catalonia and Majorca; and in 1484, when its prosperity was threatened, a semi-fabulous person, Clémence Isaure, is said to have brought about a revival by instituting fresh prizes. The town of Toulouse never ceased to supply funds of some kind. In 1513 French poems were first admitted in the competitions, and under Louis XIV. (from 1679) these were alone held eligible. This unfair arrangement, by which some of the leading poets of northern France profited, held good till 1893, when the town very properly transferred its patronage to a new *Escolo Moundino*,[2] but very soon restored its support to the older institution, on learning that Provençal poetry was again to be encouraged.] In the two centuries that followed the glorious mediæval period we have a succession of works, chiefly of a didactic and edifying character, which scarcely belong to the realm of literature proper, but at

[1] In accordance with general usage, we are employing the term Provençal for the whole of the South of France, save where special reservation is made.

[2] *Moundino*, *i.e.*, of Toulouse; a common designation, derived from Raymond, the familiar name of the Counts of Toulouse.

least served to keep alive some kind of literary tradition. This dreary interval was relieved by a number of religious mystery plays, which, though dull to us, probably gave keen enjoyment to the people, and represent a more popular *genre*; the latest that have come down to us may be placed between the years 1450–1515. Not only did the literature deteriorate during this period, but dialects took the place of the uniform literary language employed by the troubadours, while the spoken tongue yielded more and more to French. In 1539 François I. forbade the use of Provençal in official documents—a fact that is worthy of note only as being significant in itself, not as an important factor in the decadence of Provençal letters.

On the contrary, just about this time there are signs of a revival. In 1565 the Gascon, Pey de Garros, translated the Psalms into his dialect, and two years later published a volume of poems. His love for his native tongue is genuine, and his command over it considerable; he deplores its neglect, and urges others to follow his example. Auger Gaillard (*c.* 1530–1595) does infinitely less credit to his province: the popularity of his light pieces was probably due to their obscenity. More in the spirit of Garros is the charming trilingual *Salut* composed by the famous du Bartas in honour of a visit of Marguerite de Valois to Nérac (1579): three nymphs dispute as to whether she should be welcomed in Latin, French, or Gascon, and the last, of course, wins the day. Provence proper gave birth to a poet of considerable importance in Louis Bellaud de la Bellaudière (1532–1588), of Grasse, who, after studying at Aix, enlisted in the royal armies, and was made a prisoner at Moulins in 1572. During his captivity he wrote poems inspired by real love of liberty and of his native country (*Don-Don infernal*, 1584 or 1585). At Aix Bellaud subsequently became the centre of a literary circle which included most of the local celebrities; all of these paid their tribute to the poet's memory in the edition of his works published by his uncle, Pierre Paul, himself the author of pieces of small value, included in the same volume (*Lous Passatens, Obros et rimos*, &c., Marseilles, 1595). Even when Bellaud is wholly frivolous, and intent on worldly pleasures only, his work has interest as reflecting the merry, careless life of the time.

A writer very popular in Provence for the light-hearted productions of his youth was Claude Brueys (1570–1650), remarkable chiefly for comedies that deal largely with duped husbands (*Jardin deys Musos provensalos*, not published till 1628). There is a certain charm, too, in the comedies of Claude's disciple, Gaspard Zerbin (*La Perlo deys musos et coumedies prouvensalos*, 1655); and those critics who have read the plays of Jean de Cabanes (1653–1712) and of Seguin (of Tarascon, *c.* 1640), still in MS., speak highly of them. The most consistently popular form of poetry in the South of France was always the *noël*. There has been no limit to the production of these; but very rarely does the author deserve special mention. An exception must be made in the case of Nicholas Saboly (1614–1675), who produced the best pieces of this class, both as regards beauty of language and the devotion they breathe. They have deservedly maintained their popularity to the present day. In Languedoc four poets have been cited as the best of the age—Goudelin, Michel, Sage, and Bonnet. This is certainly so in the case of Pierre Goudelin (province Goudouli, 1579–1649), of Toulouse, the most distinguished name in South French literature between the period of the troubadours and that of Jasmin. He had a good classical education, traces of which appear in all his poetry, his language and his manner being always admirable, even where his matter is lacking in depth. He is often called "the Malherbe of the South," but resembles that writer only in form: his poetry, taken as a whole, has far more sap. Goudelin essayed and was successful in almost every short *genre* (*Lou Ramelet Moundi*, 1617, republished with additions till 1678), the piece of his which is most generally admired being the stanzas to Henri IV., though others will prefer him in his gayer moods. He enjoyed enormous popularity (extending to Spain and Italy), but never prostituted his art to cheap effects. His influence, especially but not exclusively in Provence, has been deep and lasting. The fame of Jean Michel, of Nîmes, rests on the *Embarras de la foire de Beaucaire*, a poem of astonishing vigour, but deficient in taste. Daniel Sage, of Montpellier (*Las Foulies*, 1650), was a man of loose morals, which are reflected in nearly all his works: his moments of genuine inspiration from other causes are rare. More worthy of being bracketed with Goudelin is the *avocat* Bonnet, author of the best among the open-air plays that were annually performed at Béziers on Ascension Day: a number of these (dated 1616–1657) were subsequently collected, but none can compare with the opening one, Bonnet's *Jugement de Pâris*. Another very charming poet is Nicolas Fizes, of Frontignan, whose vaudeville, the *Opéra de Frontignan* (1670), dealing with a slight love intrigue, and an idyllic poem on the fountain of Frontignan, show a real poetic gift. A number of Toulouse poets, mostly *lauréats* of the Academy, may be termed followers of Goudelin: of these, François Boudet deserves mention, who composed an ode, *Le trinfe del Moundi* (1678), in honour of his native dialect. The classical revival that may be noted about this time is also generally ascribed to Goudelin's influence. Its most distinguished representative was Jean de Valès, of Montech, who made excellent translations from Virgil and Persius, and wrote a brilliant burlesque of the former in the manner of Scarron (*Virgile deguisat*, 1648; only four books published). He also composed a pastoral idyll, which, though too long and inclined to obscenity, contains much tender description. The greatest of the pastoral poets was François de Cortete (1571–1655), of Prades, whose comedies, *Ramounet* and *Miramoundo* (published, unfortunately with alterations, by his son in 1684), are written with such true feeling and in so pure a style that they can be read with real pleasure. A comedy of his dealing with Sancho Panza in the palace of the Duke is being edited. It is difficult to understand the enormous popularity of Daubasse (1664–1727), of Quercy, who belonged to the working classes; he was patronized by the nobility in exchange for panegyrics. Gascony produced two typical works in the 17th century: Ader's *Gentilhomme gascoun* (1610) and Dastros's *Trinfe de la langue gascoune* (1642). The former depicts a regular boasting Gascon, who distinguishes himself in everything; while the latter is a plea in favour of the Gascon tongue, inspired by a genuine love of country. Gabriel Bedout (*Parterre gascoun*, 1642) is chiefly noted for his amorous *solitari*, called forth by the sufferings he endured from a hard-hearted mistress. Louis Baron (b. 1612), living peacefully in his native village of Pouyloubrin, celebrated it with great tenderness.

In the 18th century the number of authors is much larger, but the bulk of good work produced is not equally great in proportion. The priests are mainly responsible for the literary output of Languedoc. Claude Peyrot (1709–1795), one of them, celebrates his county with true rural spirit in the *Printemps rouergat* and *Quatre Sosous*. But the chief of the band is the Abbé Favre (1727–1783), the prior of Celleneuve, whose *Sermoun de Moussu Sistre*, delivered by a drunken priest against intemperance, is a masterpiece. He also wrote a successful mock-heroic poem (*Siège de Caderousse*), travesties of Homer and Virgil, a prose novel depicting the country

manners of the time (*Histoire de Jean l'ont pris*), and two comedies, which likewise give a vivid picture of the village life he knew so well. Two genuine poets are the brothers Rigaud, of Montpellier: Auguste's (1760–1835) description of a vintage is deservedly famous; and Cyrille (1750–1824) produced an equally delightful poem in the *Amours de Mounpèïé*. Pierre Hellies, of Toulouse (d. 1724), a poet of the people, whose vicious life finds an echo in his works, has a certain rude charm, at times distantly recalling Villon. In the Provence Toussaint Gros (1698–1748), of Lyons, holds undisputed sway. His style and language are admirable, but unfortunately he wasted his gifts largely on trivial *pièces d'occasion*. Coye's (1711–1777) comedy, the *Fiancé paré*, is bright and still popular, while Germain's description of a visit paid by the ancient gods to Marseilles (*La Bourrido dei Dious*, 1760) has considerable humour. In Gascony the greatest poet is Cyrien Despourrins (1698–1755), whose pastoral idylls and mournful chansons, which he himself set to music, are imbued with tenderness and charm (most of them were collected at Pau, in 1828).

The Revolution produced a large body of literature, but nothing of lasting interest. However, it gave an impetus to thought in the South of France, as elsewhere; and there, as elsewhere, it called forth a spirit of independence that was all in favour of a literary revival. Scholars of the stamp of Raynouard (1761–1863), of Aix, occupied themselves with the brilliant literary traditions of the Middle Ages; newspapers sprang up (the Provençal *Bouil-Abaisso*, started by Désanat, and the bilingual *Lou Tambourin et le Menestrel*, edited by Bellot, both in 1841); poets banded together and collected their pieces in volume form (thus, the nine *troubaire* who published *Lou Bouquet prouvençaou* in 1823). Much has been written about the *précurseurs du Félibrige*, and critics are sorely at variance as to the writers that most deserve this appellation. We shall not go far wrong if we include in the list Hyacinthe Morel (1756–1829), of Avignon, whose collection of poems, *Lou Saboulet*, has been republished by Mistral; Louis Aubanel (1758–1842), of Nîmes, the successful translator of Anacreon's Odes; Auguste Tandon, "the troubadour of Montpellier," who wrote *Fables, contes et autres pièces en vers* (1800); Fabre d'Olivet (1767–1825), the versatile *littérateur* who in 1803 published *Le Troubadour: Poésies occitaniques*, which, in order to secure their success, he gave out as the work of some mediæval poet; Diouloufet (1771–1840), who wrote a didactic poem, in the manner of Virgil, relating to silkworm-breeding (*Leis magnans*); Jacques Azaïs (1778–1856), author of satires, fables, &c.; D'Astros (1780–1863), a writer of fables in Lafontaine's manner; Castil-Blaze (1784–1857), who found time, amidst his musical pursuits, to compose Provençal poems, intended to be set to music; the Marquis de Fare-Alais (1791–1846), author of some light satirical tales (*Las Castagnados*). While these writers were all more or less academic, and appealed to the cultured few, four poets of the people addressed a far wider public: Verdié (1779–1820), of Bordeaux, who wrote comic and satirical pieces; Jean Reboul (1796–1864), the baker of Nîmes, who never surpassed his first effort, *L'ange et l'enfant* (1828)[1]; Victor Gelu (1806–1885), relentless and brutal, but undeniably powerful of his kind (*Fenian et Grouman; Dix chansons provençales*, 1840); and, greatest of them all, the true and acknowledged forerunner of the *félibres*, Jacques Jasmin (1798–1864), the hairdresser of Agen, whose poems, both lyrical and narrative, continue to find favour with men of the highest culture and literary attainments, as with the villagers for whom they were primarily intended.

While much of this literature was still in the making, an event took place which was destined to eclipse in importance any that had gone before. In 1845 Joseph Roumanille (1818–1891), a gardener's son, of Saint-Remy (Bouches-du-Rhône), became usher in a small school at Avignon, which was attended by Frédéric Mistral (*q.v.*), a native of the same district, then fifteen years of age. The former, feeling the germs of poetry within him, had composed some pieces in French; but, finding that his old mother could not understand them, he was greatly distressed, and determined thenceforth to write in his native dialect only. These poems revealed a new world to young Mistral, and spurred him on to the resolve that became the one purpose of his life—*de remettre en lumière et conscience de sa gloire cette noble race qu'en plein '89 Mirabeau nomme encore la nation Provençale*. There is no doubt that Mistral's is the more puissant personality, and that his finest work towers above that of his fellows; but in studying the Provençal renaissance, Roumanille's great claims should not be overlooked, and they have never been put forward with more force than by Mistral himself (in the preface to his *Isclos d'oro*). Roumanille's secular verse cannot fail to appeal to every lover of pure and sincere poetry (*Li Margaritedo*, 1836–1847; *Li Sounjarello*, 1852; *Li Flour de Sauvi*, 1850–1859, &c.), his *noëls* are second only to those of Saboly, his prose works (such as *Lou mege de Cucugnan*, 1863) sparkling with delightful humour. He it was who in 1852 collected and published *Li Prouvençalo*, an anthology in which all the names yet to become famous, and most of those famous already (such as Jasmin), are represented. In 1853 he was one of the enthusiastic circle that had gathered round J. B. Gaut at Aix, and whose literary output is contained in the *Roumavagi dei Troubaire* and in the shortlived journal *Lou gay saber* (1854). At the same time the first attempt at regulating the orthography of Provençal was made by him (in the introduction to his play, *La Part dou bon Dieu*, 1853). And in 1854 he was one of the seven poets who, on May 21st, forgathered at the castle of Fontségugne, near Avignon, and founded the *Félibrige*. [The etymology of this word has given rise to much speculation: the one thing certain about the word is that Mistral came across it in an old Provençal poem, which tells how the Virgin meets Jesus in the temple, among the seven *félibres* of the law. The outlines of the constitution, as finally settled in 1876, are as follows: The region of the *Félibrige* is divided into four *mantenenço* (Provence, Languedoc, Aquitaine, and Catalonia[2]). At the head of all is a *consistori* of fifty (called *majourau*), presided over by the *Capoulié*, who is chief of the entire *Félibrige*. The head of each *mantenenço* is called *sendi* (who is at the same time a *majourau*); and at the head of each "school" (as the subdivisions of the *mantenenço* are called) is a *cabiscòu*. The ordinary members, unlimited in number, are *mantenèire*. Annual meetings and *fêtes* are organized. The most widely read of the *Félibrige* publications is the *Armana Prouvençau*, which has appeared annually since 1855, maintaining all the while its original scope and purpose; and though unpretentious in form, it contains much of the best work of the school.[3]] The other

[1] One of his chief titles to fame is that, together with Alphonse Dumas, he drew the attention of Lamartine to Mistral's *Mirèio*. Roumanille and Mistral showed their gratitude by republishing the best pieces of these two *précurseurs*, together with those of Castil-Blaze and others, in *Un Liame de Rasin*, 1865.

[2] One of the most pleasing features of the movement is the spirit of fraternity maintained by the *félibres* with the poets and literary men of northern France, Spain, Italy, Rumania, Germany, and other countries.

[3] In common with so many other productions of the *Félibrige*, this Almanac is published by the firm J. Roumanille, Libraire-Éditour, Avignon.

six were Mistral, Aubanel, A. Mathieu (a schoolfellow of Mistral's at Avignon), E. Garcin, A. Tavan, and P. Giera (owner of the castle). Of these, Théodore Aubanel (1829–1886, of Avignon, son of a printer and following the same calling) has alone proved himself worthy to rank with Mistral and Roumanille. "Zani," the girl of his youthful and passionate love, took the veil; and this event cast a shadow over his whole life, and determined the character of all his poetry (*Lou mióugrano entre-duberto*, 1860; *Li filho d'Avignoun*, 1883). His is, without a doubt, the deepest nature and temperament among the *félibres*, and his lyrics are the most poignant. He has a keen sense of physical beauty in woman, and his verse is replete with suppressed passion, but he never sinks to sensuality. His powerful love drama *Lou pau dou peccat* was received with enthusiasm at Montpellier in 1878, and successfully produced (some years later in Arène's version) by Antoine at his Théâtre Libre—no mean criterion. It is the only play of real consequence that the school has yet produced.

We need not do more than glance at the work of the fourth of the group of poets who alone, amidst the numerous writers of lyrics and other works that attain a high level of excellence, appear to us to have so far secured permanent fame by the magnitude of their achievement. Félix Gras (1844–1891) settled at Avignon in his youth. His rustic epic, *Li Carbounié* (1876) is full of elemental passion and abounds in fine descriptions of scenery, but it lacks proportion. The heroic *geste* of *Toloza* (1882), in which Simon de Montfort's invasion of the South is depicted with unbounded vigour and intensity, shows a great advance in art. *Li Roumancero provençal* (1887) is a collection of poems instinct with Provençal lore, and in *Li Papalino* (1891) we have some charming prose tales that bring to life again the Avignon of the popes. Finally, the poet gave us three tales dealing with the period of the Revolution (*Li Rouge dou Miejour*, &c.); their realism and literary art called forth general admiration.[1]

A few lines must suffice for some of the general aspects of the movement. It goes without saying that all is not perfect harmony; but, on the whole, the differences are differences of detail only, not of principle. While Mistral and many of the best *félibres* employ the dialect of the Bouches-du-Rhône, others, who have since seceded as the *Félibrige latin* (headed by Roque-Ferrier), prefer to use the dialect of Montpellier, owing to its central position. A third class favour the dialect of Limousin, as having been the literary vehicle of the troubadours; but their claim is of the slenderest, for the *félibres* are in no sense of the word the direct successors of the troubadours. Nearly all the leaders of the *Félibrige* are Legitimists and Catholics, their faith being the simple faith of the people, undisturbed by philosophic doubts. There are exceptions, however, chief among them the Protestant Gras, whose *Toloza* clearly reflects his sympathy with the Albigenses. Yet this did not stand in the way of his election as *Capoulié*—a proof, if proof were needed, that literary merit outweighs all other considerations in this artistic body of men. Finally, it may be noted that the *félibres* have often been accused of lack of patriotism towards northern France, of schemes of decentralization, and other heresies; but none of these charges holds good. The spirit of the movement, as represented by its leaders, has never been expressed with greater terseness, force, and truth than in the three verses set by Félix Gras at the head of his *Carbounié*: "I love my village more than thy village; I love my Provence more than thy province; I love France more than all."

[1] Gras was *Capoulié* from 1891 till 1901, succeeding his brother-in-law, Roumanille, who held the office from 1888 till 1891. The first *Capoulié* was, of course, Mistral (1876-1888). Gras's successor was Pierre Devolny, of Die (appointed in April 1901), who has done good work, but has yet to prove himself worthy of the supreme distinction conferred on him by his fellow-poets.

(H. O.)

Providence, a city of the United States, capital of the state of Rhode Island, is situated at the head of Narragansett Bay, in 41° 49′ 22″ N. and 71° 24′ 48″ W. Its area is 18·29 square miles. Its surface is hilly, rising to the height of 204 feet on the "East Side." The park area is 542 acres. Roger Williams Park (102 acres) is the largest. Its population in 1900 was 175,597, of whom 55,855 were foreign-born and 4817 were negroes. Among 53,131 adult males 3830 were illiterate (unable to write), of whom 3384 were foreign-born. The death-rate in 1900 was 19·9; in 1890 it was 21·1. Brown University, seventh in age of the colleges of the United States, is the chief educational institution. Other institutions are the Rhode Island School of Design, the Rhode Island Normal School, four high schools, the Friends' Boarding School, and the Roman Catholic Academy of the Sacred Heart. The University Library and the Providence Public Library number about 125,000 volumes each. The Providence Athenæum contains 70,000 volumes. Most noteworthy is the library of Americana, now the property of Brown University, begun by John Carter Brown—the most complete collection in the world of books relating to early American history. Of benevolent institutions the most noted are the Dexter asylum for the poor, the Butler hospital for the insane, and the Rhode Island hospital. The oldest edifice for religious purposes is the First Baptist Meeting House, erected in 1775 "for the public worship of Almighty God, and also to hold Commencements in." The largest is the Roman Catholic Cathedral. There are in all 129 places of worship. Of these, 21 are Baptist, 10 Congregational, 14 Episcopal, 18 Methodist, 16 Roman Catholic, 4 Unitarian, 3 Universalist, and 4 Presbyterian. Of public buildings there are the City Hall, the Providence County Court House, and the Rhode Island Normal School. The old State House (1762) is a fair specimen of colonial architecture. The finest building in the city is the State Capitol. With its approaches it cost about $3,500,000. Seven railways, all controlled by one corporation, enter the city. Besides steamboats plying upon Narragansett Bay and to New York, steamships sail regularly to Philadelphia, Baltimore, Norfolk, Savannah, and Kingston, Jamaica. The city is a great distributing centre for central New England.

Providence is one of the great manufacturing centres of the Union. It is the leading city in the manufacture of jewellery, the total product of which in 1900 was valued at $12,719,124. In all industries in 1900 there were 1933 manufacturing establishments, having a capital of $83,513,679, and employing an average number of 42,693 wage-earners, who received wages amounting to $19,998,362. The total products were valued at $88,168,897. Among these products the most important, apart from jewellery, were: worsted goods ($16,603,252), silver ware ($8,884,408), foundry and machine-shop products, rubber and elastic goods,

cotton and woollen goods, and oleomargarine. It is the growth of manufacturing which accounts for the fact that the population, once almost wholly native-born, has received an element of foreigners amounting to almost one-third. In 1899 the valuation placed upon real estate was $146,701,900. Upon personal property the valuation was $41,799,880. The revenue of the municipality was $3,878,439. The net debt 1st April 1900 was $14,008,484. It is a banking centre for a region of mammoth factories. There are nineteen national banks, with a total capital of $15,113,523 and deposits of $14,609,832 ; two state banks, with a capital of $320,000 and deposits of $446,743 ; five trust companies, with a capital of $4,150,000 and deposits of $27,745,108, make a total capital for all banking and trust companies of $19,583,523 and total deposits of $42,801,684. There are five savings banks, with deposits of $38,855,589. The clearings for the year ending 30th June 1900 were $338,132,500. (W. H. MU.)

Provo, a city of Utah, U.S.A., capital of Utah county, at the west base of the Wasatch mountains, on the Provo river, and on the Oregon Short Line and the Rio Grande Western railways, near the east shore of Utah Lake, north of the centre of the state, at an altitude of 4532 feet. It has a level site and a regular plan, and is divided into five wards. It contains the insane asylum of Utah. Population (1880), 3432; (1890), 5159; (1900), 6185, of whom 1176 were foreign-born.

Prussia, the principal state of Germany, ranking first in both area and population, though only twentieth in respect of density of population. More than 5 per cent. of the entire surface of Prussia consists of moorland, some of it high (heathy) moors, some of it (the smaller portion) low boggy moors. Hanover—more particularly the districts of Osnabrück, Stade, Lüneburg, and Aurich (East Friesland) —and Schleswig-Holstein possess between them nearly 3000 square miles of this variety of surface. Another 1100 square miles are in East Prussia; and the rest, about 1500 square miles in all, occur chiefly in the provinces of Pomerania, Brandenburg, Posen, and Saxony. Since 1870 the Prussian Government, as well as the authorities of the province of Hanover, and various private persons, have started several more or less successful schemes for the reclamation of these waste tracts. The region to which the Prussian Government has principally directed its attention is the great Bourtanger Moor, between the Ems and the Dutch frontier, in the north-west of the province of Hanover. There colonies were established as long ago as the first half of the 17th century—Papenburg, for example (1630)—chiefly for the purpose of cutting turf for fuel; and in East Friesland, in the first place at the instigation of Frederick the Great, over eighty similar colonies, aggregating in all 20,000 persons, were planted between 1765 and 1800, but nothing effective was done for the real reclamation of the moorland. But in 1870 the Prussian Government turned its attention to the matter, and proceeded to cut navigable canals through the moorland, and appointed a special commission to deal with its reclamation generally. These efforts received a further impulse from the founding of an experimental station near Bremen in 1877. In consequence of the work done in the laboratory attached to this station, as well as of experiments conducted on the moors themselves, the province of Hanover organized a new system of colonization in 1887. Having bought some 1100 acres beside the main canal which traverses the Bourtanger Moor from north to south, they drained the land and divided it into 25-acre plots, which they granted to occupiers free, with the option of purchase, the principal condition being that the grantees should first reclaim 5 acres. This project proving successful, induced the Prussian Government in 1899 to embark in similar enterprises on the Wiesder Moor (Marcardsmoor) along the line of the Ems-Jade canal, between Aurich and Jade Bay. In 1902 Prussian estimates embraced an item of over £131,000 for these and similar improvements. Other private ventures of some importance have been made at Friedrich-Wilhelmsdorf near Loxstedt, a few miles south-east of Bremerhafen, on the Kehdinger Moor, on the west side of the estuary of the Elbe, in Schleswig-Holstein, and in East Prussia. In 1883 a national society was founded for the reclamation and cultivation of the moorlands of Germany.[1]

Population.—The following table gives particulars of the area and population of the several provinces of the kingdom in the years 1890, 1895, and 1900, as well as the chief religious statistics for 1895 :—

Provinces.	Area in sq. miles.	Population, 1890.	Population, 1895.	Population, 1900.	Density per sq. mile, 1900.	Protestants, 1895.	Roman Catholics, 1895.	Jews, 1895.
East Prussia	14,278	1,958,663	2,006,689	1,996,626	139	1,724,374	266,641	14,364
West Prussia	9,852	1,433,681	1,494,360	1,563,658	159	715,581	758,168	20,238
Berlin (city)	25	1,578,794	1,677,304	1,888,848	75,554	1,426,591	155,363	86,152
Brandenburg	15,376	2,541,783	2,821,695	3,108,554	202	2,681,637	118,265	18,394
Pomerania	11,625	1,520,889	1,574,147	1,634,832	140	1,530,003	31,739	11,661
Posen	11,181	1,751,642	1,828,658	1,887,275	168	561,201	1,227,197	40,019
Silesia	15,561	4,224,458	4,415,309	4,668,857	300	1,980,552	2,384,754	47,593
Saxony	9,747	2,580,010	2,698,549	2,832,616	290	2,498,748	187,559	7,850
Schleswig-Holstein	7,335	1,219,523	1,286,416	1,387,968	189	1,257,454	24,184	3,702
Hanover	14,865	2,278,361	2,422,020	2,590,939	174	2,094,604	311,457	15,065
Westphalia	7,801	2,428,661	2,701,420	3,187,777	409	1,298,852	1,378,676	19,359
Hesse-Nassau	6,058	1,664,426	1,756,802	1,897,981	313	1,224,021	482,752	45,725
Rhine Province	10,420	4,710,391	5,106,002	5,759,798	552	1,434,715	3,610,142	49,018
Hohenzollern	441	66,085	65,752	66,780	151	2,566	62,608	576
Total	134,565	29,957,367	31,855,123	34,472,509	256	20,430,899	10,999,505	379,716

Between 1880, when the total population numbered 27,279,111, and 1900 there was an increase of 7,193,398 persons, or at the rate of 26·4 per cent. per annum. For the period 1890–99 the marriage-rate averaged 8·2 per 1000 inhabitants, the birth-rate 38·1 per 1000, and the death-rate 23·3 per 1000. In respect of illegitimacy, while for the same period the percentage of illegitimate births to total births was as much as 14·25 in the city of Berlin, and between 10 and 11 per cent. in each of the provinces of Pomerania, Brandenburg, and Saxony, the average for the whole kingdom was only 7·76. The densely-peopled manufacturing and mining provinces of Westphalia and the Rhineland have by far the best record in this respect, their averages being 2·61 and 3·87. The present population is concentrated most densely (300 to 552 inhabitants per square mile) in the manufacturing districts of Rhenish Prussia, Westphalia, the adjacent Hesse-Nassau, and in the extreme south-east of the kingdom, the coal and zinc and iron region of Silesia. The average density in the

[1] See the annual *Mitteilungen* of this society (published at Berlin); Fleischer, *Die Besiedelung der nordwestdeutschen Hochmoore* (Berlin, 1894); Rimpau, *Die Bewirthschaftung des Rittergutes Cunrau* (Berlin, 1887); and F. P. Koenig, *Agriculture in Germany* (*Brit. Cons. Report*, Misc. Series, No. 452, 1898).

agricultural provinces of East and West Prussia, Posen, Pomerania, Brandenburg, Saxony, Hanover, and Schleswig-Holstein varies between 139 and 290 inhabitants per square mile, or, roughly, one-half of the density in the manufacturing provinces. According to the census returns of 1900, there were 1031 females for every 1000 males, as compared with 1037 females in 1880. In 1900 there were in Prussia one city with a population exceeding one million inhabitants, seven towns between 200,000 and 500,000; fourteen between 100,000 and 200,000; twenty-four between 50,000 and 100,000; and eighty-nine between 20,000 and 50,000. The emigration decreased from 145,679 in 1881 to 50,461 in 1886; then, after going up to 76,196 in 1892, it rapidly declined to 12,471 in 1900. The number of suicides varies from 5000 to 6500 annually, the average being 19 for every 100,000 inhabitants, or one less than the average for all Germany. In 1890 the island of Heligoland was ceded by Great Britain to Germany, and in the following year it was administratively attached to the Prussian province of Schleswig-Holstein.

Of the total population in 1900, 55·6 per cent. were classed as urban and 44·4 as rural, *i.e.*, as living in places of less than 2000 inhabitants each. In 1895 the foreign residents embraced 63,289 natives of Austria-Hungary, 47,715 natives of Holland, 18,998 of Russia, 24,389 of Denmark, 10,062 of Switzerland, 8120 of Great Britain, 7327 Armenians, 6564 of Belgium, 6301 of Norway and Sweden, and 2127 of France. Adverting to the religious statistics, it will be seen that 64·14 per cent. of the entire population belonged (1895) to the Protestant State Church, 34·53 per cent. to the Roman Catholic Church; and 1·19 were Jews. Of races other than Teutonic the population of Prussia embraced 2,922,475 Slavs (Masurians, Cassubians), 117,637 Lithuanians, 64,254 Wends, and 74,069 Bohemians and Moravians. In 1895, 11,113,794 persons, or 34·9 per cent. of the population, were engaged in agriculture, cattle and sheep breeding, &c.; 12,196,352, or 38·3 per cent., in mining and industry; 3,585,430, or 11·3 per cent., in commerce and trade; 1,671,827, or 5·2 per cent., in the learned professions; 658,896 in domestic service; 261,302 in forestry, fishing, &c.; and 2,002,714, or 6·3 per cent., had no profession.

Agriculture.—Out of the total area of cultivable land in the German empire, fully 66 per cent. belongs to Prussia, namely, 53,002,600 acres (1895). Of this total less than 5 per cent. was divided into farms of less than 5 acres each, 32·14 per cent. amongst farms ranging from 5 to 50 acres, 32·01 per cent. amongst farms ranging from 50 to 250 acres, and the rest amongst farms exceeding 250 acres. The provinces in which large estates (up to 2500 acres and more) are the rule, are Pomerania, Posen, Silesia, East Prussia, Brandenburg, West Prussia, and Saxony, in the order named. The estates of the old landed gentry (*Rittergüter*) of Prussia, taking the estates above 500 acres each, aggregate in all some 13,428,000 acres. Small estates (peasant holdings) prevail principally in the Rhine province, Hesse-Nassau, and Westphalia, and to some extent also in Hanover, Silesia, and Saxony; but large peasant holdings (50 to 250 acres) exist only in Schleswig-Holstein, Hanover, East Prussia, Westphalia, Saxony, and Brandenburg. Notwithstanding the continuous decline in prices, and other drawbacks from which agriculture suffered in all the older countries of Europe during the last quarter of the 19th century, the Prussian farmers have on the whole fairly well maintained their position, owing mainly to the fact that they have been both eager and skilful in availing themselves of the opportunities offered by the progress of agricultural knowledge. One of the latest departures in this field has been the establishment of central stations for the distribution of electric power to the estates in its neighbourhood, the power to be used for driving both fixed and movable machinery (mills, chaff-cutters, threshing machines, ploughs, &c.), for lighting buildings and houses, for cooking and heating, and on large estates for giving signals and conveying orders. The cultivation of the beetroot for sugar has had a far-reaching effect upon Prussian agriculture, especially in the provinces of Saxony, Silesia, Posen, Hanover, West Prussia, Pomerania, Brandenburg, the Rhine Province, and other parts of the kingdom, where the beetroot is extensively cultivated. Owing to the deep cultivation of the soil and the incessant hoeing which the beet crop requires, the three or four crops which follow it are invariably good, and the liability to failure of the immediately succeeding crop is reduced to a minimum. Moreover, the fiscal policy of the Prussian Government has been of first-rate assistance to the Prussian farmer. And hand in hand with the cultivation of the beetroot has gone the cultivation of barley and chicory, crops of scarcely inferior value from the cultivator's point of view. Barley is grown on more than 11¼ million acres. The Prussian province of Saxony produces one-half of the total quantity of chicory yielded every year throughout the empire; the principal centres for its manufacture in Prussia are Magdeburg, Berlin, and Breslau.

The Prussian Government, in conjunction with the provincial authorities, also gives encouragement to the breeding of live stock, which it endeavours to improve by subsidizing and maintaining stud-farms. It is, however, the breeding of horses to which it especially devotes itself, supporting about two dozen stud-farms for this end, of which the most famous are at Trakehnen in East Prussia, at Graditz near Torgau in the province of Saxony, and at Beberbeck between Cassel and Hoxter. The only stud, however, where thoroughbred stallions are kept is at Graditz. The most noticeable features in connexion with the live stock of Prussia are the altogether unusual diminution in the number of sheep (caused in large part by the fall in the price of wool), the even greater relative increase in the number of pigs, and the increase, though at a much smaller rate, in the numbers of the cattle and horses. For instance, sheep in 1873 numbered 19,666,800, but in 1900 not more than 6,989,400. Pigs, however, increased from 4,294,900 in the former year to 10,954,000 in the latter; cattle from 8,639,500 to 10,865,300; and horses from 2,282,400 to 2,913,000.

In the matter of freights also the Government renders material assistance to the Prussian farmer. The State owns the railways, and carries agricultural produce, especially such as is destined for export, at lower preferential rates. See further under *Communications* below.

The crops chiefly grown are potatoes (5,477,095 acres in 1900), hay (8,025,230 acres), beetroot, rye (11,277,340 acres), oats (6,710,930 acres), wheat (2,999,860 acres), and barley (2,205,625 acres). In 1900 some 11,500 acres were planted with tobacco, the yield of which (about 10,000 tons) was valued at £420,000; about 5500 acres were planted with hops. In 1899–1900 there were 308 sugar factories at work, their total production being 1,339,270 tons of sugar; 5103 breweries produced 690,250,000 gallons of beer, and 6331 distilleries produced 67,598,900 gallons of pure alcohol. Wheat is grown more especially in Silesia, Saxony, the Rhine Province, East Prussia, and Hanover; barley in Silesia and Saxony; oats in Silesia, East Prussia, Hanover, the Rhine Province, and the northern provinces generally; potatoes in Silesia, Brandenburg, and Posen; and rye commonly in every province of the kingdom. Brandenburg produces about one-half of the tobacco; the hops are chiefly grown in Posen. Of the entire area about 23 per cent. is covered with forests.

Viticulture.—The principal wine-growing districts of Prussia are the Rheingau and the Rhine Province, though wine is also produced in Silesia, Westphalia, and a few other districts. The valleys of the Nahe, Saar, Moselle, and Ahr all produce excellent wine. The total area planted with vines in 1900 was 45,400 acres, and on this the yield was 6,752,000 gallons, valued at £767,235, as compared with an average of 50,000 acres planted and a yield of 5,500,000 gallons during the period 1880–90. The Prussian State owns several vineyards in the Rhine district, including 240 acres of the choicest vineyards in the Rheingau—Rauenthal, Eltville, Marcobrunn, Steinberg, Erbach, Rüdesheim, and Assmannshausen; and it has also bought several acres of vineyards along the Moselle. During the last two or three years of the 19th century the German vine-growers suffered, in common with vine-growers in other countries of Europe, from the attacks of diseases and insect pests—*e.g.*, *Peronospora viticola*, *Oïdium Tuckeri*, and *Phylloxera vastatrix*. The last named alone has already cost the Imperial Government £400,000 in efforts to stamp it out. This industry, being so near the great mining and manufacturing districts of western Prussia, naturally suffers from the increasing scarcity and dearness of manual labour. These hindrances the vintagers counteract to some extent by forming associations for the co-operative manufacture, storage, sale, and advertising of their wine. The principal school of viticulture in Prussia is at Geisenheim in the Rheingau. The best wines of the Rhine and Moselle region which come into commerce are largely sold by public auction.

Mining and Metal Industries.—Prussia still retains her pre-eminence as the largest producer of coal, zinc, salt, lead, and copper amongst the states of the German empire, though in respect of iron she comes second to Alsace-Lorraine. Of the aggregate German output of coal Prussia now supplies over 93 per cent., namely, the huge total of 101,966,158 tons, valued at £43,912,500 in 1900, as compared with some 47,000,000 tons in 1882, representing an increase of about 117 per cent. Westphalia produces the largest quantity, namely, 42,557,146 tons, valued at £17,958,000,

in 1900; next comes the Rhine Province, that is, the Saar, Aachen, Düsseldorf, and Roer coal-fields, with 29,010,089 tons, of the value of £14,149,500; and then the Silesian coal-field, with 29,596,738 tons, valued at £11,420,500. Since the high prices of 1900 the Prussian Government has spent £1,250,000 in the purchase of coal-fields so as to be independent of market fluctuations, temporary scarcity, and the manipulations of middlemen. The Prussian State is a large owner of mines and salines; these in 1902 were estimated to yield a revenue of 9½ millions sterling. An extremely important *rôle* is played in the coal industry of Prussia by the Rhenish-Westphalian Coal Syndicate, which has its headquarters at Essen, and which from the bulk of its output (about 40 per cent. of the total German output) has succeeded in regulating the production and price of the coal-fields generally. Out of a total output of lignite for the entire German empire of 40,498,019 tons in 1900, Prussia yielded no less than 84 per cent., or a total of 34,007,542 tons, valued at £4,012,900, showing an annual increase of over 24 million tons and of 3½ millions sterling since 1882. Almost the whole of the zinc produced in Germany comes out of the Silesian mines, the amount being 636,068 tons in 1900, valued at £1,279,600, or nearly six times the amount mined in 1882. The iron production of Prussia amounted in 1900 to only 33 per cent. of the aggregate production of Germany, or a total of 4,268,069 tons, valued at £1,884,300, the increase over the output in 1882 being little more than a quarter of a million tons. The chief iron-producing regions are the Rhine Province, Westphalia, Hesse-Nassau, and Silesia. But in the production of lead Prussia enjoys almost an unchallenged monopoly, in that in 1900 she produced 147,042 tons out of 148,257, the value being £890,000; in 1882 the output amounted to 88,300 tons. And the Prussian output of manganese occupies an exactly analogous position, amounting to 58,016 tons, valued at £33,000, out of 59,204 tons. In the same year 169,447 tons of pyrites, valued at £60,750, and some cobalt were mined. Salt, one of the most valuable of the mineral products of the country, was in its various forms, but principally in the form of rock-salt, obtained to the extent of 2,476,867 tons, valued at £1,410,650, in 1900, as compared with some 550,000 tons in 1882. Ordinary salt is mined principally in the province of Saxony (Stassfurt, Aschersleben, Erfurt, Halle, Merseburg, Sangerhausen), the kali salts near Magdeburg, and Glauber salts in the Rhine Province and Hesse-Nassau. The furnaces, forges, salt-works, and similar establishments for the conversion of the raw ores into manufactured or semi-manufactured products yielded in 1900 5,781,892 tons of pig iron, valued at £19,118,400, as compared with a yield of 2,467,500 tons, valued at £7,490,000, in 1882; 155,760 tons of zinc, valued at £3,102,600; 112,170 tons of lead, of the value of £1,880,300; copper to the extent of 27,157 tons and the value of £2,069,700; silver to the extent of 6,920,150 oz., valued at £1,084,350, approximately equivalent in value to the output twenty years earlier; and 566,368 tons of sulphuric acid, valued at £727,350. The iron was worked principally in the districts of Arnsberg, Düsseldorf, Oppeln in Silesia, Treves, and Coblenz, and gave employment to 25,686 hands; the zinc, for the most part near Oppeln in Silesia, the number of hands employed being 10,779; the lead and the silver near Aachen, Oppeln, and Wiesbaden, the hands employed numbering 2716; and the sulphuric acid in all the mining districts, as well as near Potsdam, Breslau, Magdeburg, and Merseburg, and the number of hands 2969. Further, a total of 203,700 persons were employed in some 1000 foundries, puddling-mills, rolling-mills, and so forth, and they produced iron and steel materials to the weight of 1,612,000 tons and a combined value of £13,383,150. Petroleum (27,731 tons in 1900) is extracted to a limited extent at a couple of places in the province of Hanover. Down to 1899, in which year the monopoly was bought out by the Prussian Government, 150 to 250 tons of amber were mined in East Prussia. A little is also collected on the coast near Pillau.

Other Manufacturing Industries, Commerce.—During the last quarter of the 19th century Prussia developed into a great manufacturing country. Between 1882 and 1895 it was estimated that the number of persons employed in manufacturing and kindred pursuits increased in the aggregate at the rate of 34¼ per cent., but the number employed in trade and commerce increased at a vastly greater rate, namely, 60½ per cent., or from 771,323 in the first-mentioned year to 1,237,882 in 1895. Amongst the causes which have been mainly instrumental in fostering the industrial development in Prussia are those which have also contributed to the progress of Prussian agriculture, such as the fostering care of the Government (at once energetic, comprehensive, and watchful), co-operation and organization, which has been immensely facilitated by the habits of prompt obedience and order learnt in the course of the military training; the generally high intellectual level and technical and artistic skill of the workmen, due in part to the enforcement of sound elementary education and in part to the fostering care of the excellent technical high schools, trades "continuation schools," and hosts of special schools in which the arts and crafts are thoroughly and systematically taught; the use made of scientific discoveries and the power of taking advantage of scientific progress generally; the national aptitude for giving conscientious attention to minutiæ, and for thoroughness and mastery of detail; the extensive employment of commercial travellers, having command of languages, in all parts of the world; and an earnest desire to find out and meet the wants and tastes of customers. Moreover, the social and economic conditions of the people have been in their favour. Wages have on the whole been lower than, for example, in England, though since 1896 they have shown a strong upward tendency, and the standard of comfort, and even in many cases the standard of living, has been lower. Litigation, too, is more expeditious and less costly. But the Prussian manufacturer has derived no small measure of advantage from the fact that he has come into the field somewhat later than his foreign rivals. He has been enabled to utilize their experience, to profit from their drawbacks, faults, and deficiencies, and to make a clean start in the light of this extremely valuable acquired knowledge. And his interests have also been materially promoted by the commercial and fiscal policies of his Government.

The chief industrial districts are, of course, those which yield coal, with, in addition, the great cities—Berlin, Magdeburg, Hanover, Breslau, Görlitz, Stettin, Essen, Dortmund, Elberfeld-Barmen, Düsseldorf, Cologne, Aix-la-Chapelle, Crefeld, Halle, Hanover, Frankfort-on-the-Main, Saarbrücken, Höchst, Solingen, Remscheid, Hagen, Königsberg, Danzig, and many others. The iron and metal industries, especially the making of machinery, electrical plant, tramway plant, and the production of articles in wrought copper and brass, rank in the very forefront, not only in virtue of their magnitude, but also because of the remarkable rate at which they have increased and grown. In these branches Berlin, and more lately its suburbs, as well as Magdeburg and Cologne, have played an active *rôle*, though the old centres of the metallurgical and iron and steel industries in the Rhine Province and Westphalia have also expanded in an extraordinary degree. The growth of the chemical industries, which are essentially a German speciality, must also be mentioned in the front rank. The genius of men like Liebig, Wöhler, Bunsen, Runge, Hofmann, Böttiger, Kekulé, Fischer, and their pupils has made the German chemical manufacturer pre-eminent in his own special lines throughout the world. The branches in which his supremacy stands unrivalled are those which produce aniline dyes, artificial indigo, illuminants (acetylene gas, Welsbach mantles, &c.), explosives, various chemical salts, pharmaceutical preparations, cellulose, glycerine, artificial (chemical) manures, and perfumes.[1] A third branch of industry in which German genius has won triumphs of the very highest kind is shipbuilding. Here the advance has been materially assisted by the admission free of duty of materials needed for the building of ships, preferential low railway rates for the carriage of materials of native German origin, and by an indirect bounty on shipments made to the Levant, East Africa, and elsewhere, in German-built, or at least German-owned, vessels.

Communications.—Between 1880 and 1886 the State-owned lines of railway increased by 9240 miles, the increase being principally due to the policy of buying up private lines; and since 1886 there has been a further increase of 6000 miles. By law the Prussian State enjoys the right to buy up lines privately constructed after an interval of 30 years, though in many cases the interval has been shortened to 15 or even 10 years. In 1900 the State lines amounted to a total of 18,859 miles, with about 950 in process of construction; and the private lines to 1872 miles. The former total includes 590 miles in Hesse-Darmstadt, the railways of this grand-duchy having been incorporated with the Prussian railways in 1896. The building of the railways in Prussia has in almost every case been determined, or at any rate influenced, by military requirements; and this applies also to the making of private lines. The most important trunk line of Prussia is that which enters the western frontier at Herbesthal, and runs through Cologne, Düsseldorf, Hanover, Berlin, Dirschau, and Königsberg, and leaves the eastern boundary at Eydtkuhnen for St Petersburg. Generally speaking, the principal lines of the country either radiate from Berlin or run alongside the frontiers and boundaries. To the former category belong the lines which connect the capital with Hamburg and Kiel, with Stettin, with Danzig and Königsberg, with Posen and Breslau (dividing at Frankfort-on-Oder), with Dresden, with Leipzig and Bavaria, with Frankfort-on-the-Main *viâ* Halle and Erfurt, with Coblenz *viâ* Cassel, and with Cologne *viâ* Magdeburg and Brunswick. The second category embraces lines from Hamburg to Stettin, from Stettin to Posen and Breslau, and from Breslau to Halle; the ring is again taken up at Frankfort-on-the-Main, and continues up the Rhine (on both banks) to Cologne, and thence through Münster and Bremen to Hamburg. Besides these there are two other

[1] See Dr Frederick Rose, "Chemical Instruction and Chemical Industries in Germany, 1901–02," being Nos. 561 and 573 of the *Miscellaneous Series of British Diplomatic and Consular Reports.*

important lines, one connecting Hamburg with Frankfort-on-the-Main *viâ* Hanover and Cassel, the other linking Hanover with Halle. The capital invested in the State railways of Prussia increased from £7,211,150 in 1854 to £311,878,540 in 1889, and to £390,550,100 in 1899 (including £12,369,800 for the Hessian railways). In the last-mentioned year the expenditure amounted to £38,816,820 and the revenue to £66,987,740, showing a net profit of £28,170,920, or sufficient to pay interest at the rate of 7¼ per cent., as compared with 2¼ per cent. in 1854 and 6¼ per cent. in 1889. The estimated revenue from the State railways for the year 1902–03 was put at £70,602,000, against which there were expected to rank an ordinary expenditure of £44,188,000, and an extraordinary expenditure of £4,582,000. Besides these, "light railways" have been built in increasingly greater numbers since 1892. In this year they totalled 643 miles, but in 1900 reached a length of about 4350 miles, the capital invested in them amounting to nearly 30¼ millions sterling. Prussia possesses also an extensive and admirably arranged system of natural and artificial waterways, and the latter are being constantly extended and improved. For instance, in the period 1880–93 the Prussian Government spent no less than £11,677,750 upon the maintenance and construction of locks, canals, canal buildings, bridges, roadways, &c. Besides this there was a special vote of £6,197,600 for the construction of the Dortmund-Ems Canal and the improvement of the navigation of the Oder, Vistula, Spree, and other waterways in Brandenburg. The most important of the canals recently constructed, or still under construction, are the North Sea and Baltic Canal (officially the Emperor William Canal), the Trave-Elbe Canal (to give Lübeck access to the Elbe), the Dortmund-Ems Canal, and its continuation, the Dortmund-Rhine Canal, both intended to serve the coal and iron districts of Westphalia and the Rhineland; and there are also projects, which have not yet taken definite shape, for constructing a canal between Stettin and Berlin, another between Kiel and the Elbe *viâ* the Plon lakes, and a gigantic scheme known as the Midland Canal for connecting the rivers Rhine, Elbe, Weser, and Oder. The object of this last is avowedly to facilitate the transmission of the corn and other agricultural food products of the east of the kingdom to the populous manufacturing districts of the west. The mercantile marine of Prussia amounted in 1900 to 2074 vessels of an aggregate of 406,657 register tonnage. The largest ship-owning ports are Flensburg, Stettin, Kiel, Rostock, and Danzig; and Geestemünde owns the largest deep-sea fishing fleet. (Compare also HAMBURG.) The harbours of the kingdom were in 1898 entered by 61,329 sea-going vessels of 7,310,013 tons. The bulk of this traffic belonged to the ports of Danzig, Königsberg, Stettin, Rostock, Kiel, Altona, and Geestemunde. Sassnitz, Norddeich, Heligoland, Norderney, and Warnemünde all have heavy passenger traffic.

Education.—All fees are now entirely abolished in the elementary schools. The subjoined table gives statistics of the schools and universities of the kingdom in the years named:—

Institution.	No.	Teaching Staff.	No. of Students or Pupils.
Universities (1900)	11	1,503	17,407
Classical and pro-classical schools (1897–98)	327	4,994	95,196
Mixed classical and modern schools, and higher modern schools (1897–98)	145	2,170	46,214
Modern schools (1897–98)	106	1,139	27,820
Elementary schools (1896)	36,138	82,182	5,236,826
Private elementary schools (1896)	404	...	17,876
Middle schools (1896)	1,703	5,615[1]	225,497
Normal schools (1897)	126	929	11,782

The total number of children of school age (six to fourteen years) in 1896 was returned as 5,654,918. The number of public elementary schools increased from 32,613 in 1878 to 36,138 in 1896. The steady progress of education is attested by the decrease in the percentage of illiterates amongst the military and naval recruits in the annual levy, the decrease going from 2·33 per cent. in 1880 to 0·1 per cent. in 1900.

Finances.—As in all civilized countries, the national accounts of Prussia expand by leaps and bounds, and they do this in spite of the advantage which the State derives from the possession of valuable revenue-yielding properties. Of these the most important are the railways. Next in point of revenue come the mines and salines, with an estimated yield in 1902–03 of 9½ millions sterling. Then follow the State forests, yielding over 4 millions sterling in the same year, and the landed domains, yielding about £1,300,000, though the income from this source is rapidly decreasing as agriculture declines. For 1902–03 the public revenue was estimated at £130,708,360 and the expenditure at the same, as compared with a revenue and expenditure of £86,981,000 in 1890, equivalent to an increase of 66½ per cent. in 12 years. The principal sources of revenue are the railways, £70,816,400 (1902); domains and forests, £5,354,000; State lottery, £4,413,200; mines, £9,529,700; direct taxes (principally income-tax), £10,705,000; indirect taxes, £4,360,850; administrative receipts, £6,995,350; and from the general financial control, £18,806,500. The chief items of the expenditure consist of payments for religion and education, £9,529,700; for justice, £6,061,700; expenses of administration, including £44,188,000 for working the State railways, £67,050,900; interest, &c., on public debt, £13,923,170; the matricular contribution to the imperial exchequer, £17,395,600; the ministry of finance, £5,771,750; and the ministry of the interior, £3,880,300. The minimum of income upon which income-tax is levied was raised from £21 to £45 in 1883, and the sum total of incomes liable for income-tax increased from £286,200,000 in 1892–93 to £338,750,000 in 1898–1899, and the number of income-tax payers from 2,435,858 in the former year to 2,907,000 in the latter. The public debt grew from £64,363,000 in 1872 to £329,584,000 in 1900. The greater part of this debt has been incurred in the purchase of the State railways. In 1898–99 there were in all 8,024,928 savings bank books, the number having doubled since 1883; and the deposits standing to their credit amounted to £15,757,000, or an average of £1 19s. 3d. per head.

[1] In the public middle schools only.

London, 1900.

(J. T. BE)

Prussia, Rhenish, a province of Prussia, with an area of 10,423 square miles and a population of 5,759,798 (1900), ranking seventh in point of area, but first in point of population, amongst the provinces of the kingdom. The density works out at 552 inhabitants to the square mile. Like Westphalia, it is a great producer of coal and other minerals. The chief seats of the coal-mining are the vicinity of Düsseldorf, Saarbrücken and the valley of the Saar, and Aix-la-Chapelle. The total number of hands employed is 111,444 (1900). The statistics of the mines production in 1900 were as follows:—29,010,100 tons of coal, valued at £14,149,500; 5,162,400 tons of lignite, valued at £590,500; 1,158,120 tons of iron ore, valued at £659,050; 62,470 tons of zinc, valued at £275,150; 41,740 tons of lead, valued at £303,400; 51,330 tons of manganese, valued at £26,400; and 3660 tons of copper, valued at £6650: or, in all, 35,489,820 tons of minerals, valued at £16,010,650. The salt-works and smelting furnaces yielded 5131 tons of salt, valued at £3850; 24,660 tons of Glauber salts, valued at £29,850; 2,915,614 tons of iron, valued at £955,060; 38,709 tons of zinc, valued at £810,400; about 47,484 tons of lead, valued at £799,000; 1,986,730 ounces of silver, valued at £312,850; and 136,426 tons of sulphuric acid, valued at £168,050; and the forges, foundries, &c., turned out iron bars, ingots, pig-iron, &c., to the value of £25,222,100. Vines are extensively cultivated, approximately 300,000 acres being planted with vineyards, and the produce amounts annually to 5 or 6 million gallons of wine. The live stock in the same year numbered 1,156,388 cattle, 892,522 pigs, 174,201 sheep, and 190,294 horses. The sugar factories and refineries produced 53,504 tons of sugar, and the breweries, 127,182,000 gallons of beer. Co-operation is made extensive use of by the cultivators of the soil in this province, there being in 1898 some 65 farmers' associations, besides nearly 200 special associations for horse-breeding, gardening, bee-keeping, viticulture, &c. There are also nearly 120 co-operative farming societies, and 700 "co-operative casinos" for supplying their members with feeding stuffs, artificial manures, machinery, and seeds. (See further under PRUSSIA.) See *Brit. Cons. Reps.*, Nos. 452 and 454 (1898).

Prussia, East, the most north-easterly province of Prussia, with an area of 14,282 square miles, and population (1900), 1,996,626, giving 139 inhabitants to the square mile. (See further under PRUSSIA.) The live stock in 1900 numbered 1,061,221 cattle, 839,934 pigs, 622,236 sheep, and 458,063 horses. The sugar factories in the same year produced 10,440 tons of sugar; the iron foundries, goods to the value of £29,000; the breweries, 26,884,000 gallons of beer; and the distilleries (including those of West Prussia), 8,971,200 gallons of pure alcohol. The mercantile marine consisted in 1900 of 33 sea-going vessels of 15,135 tons.

Prussia, West, a north-easterly province of Prussia, with an area of 9854 square miles, and population (1900), 1,563,658. In 1899–1900 the sugar factories produced 102,670 tons of sugar; the breweries, 17,644,000 gallons of beer. (For the distilleries, see PRUSSIA, EAST.) The live stock in 1900 numbered 618,423 sheep, 637,667 cattle, 626,828 pigs, and 243,118 horses. The mercantile marine of the province in 1900 consisted of 57 vessels of 29,045 tons. (For further particulars, see under PRUSSIA, above.)

Przemyśl, a strongly fortified town in Galicia, Austria. There is a strong garrison of 8514 men, composed of all arms, including 4 regiments of artillery. The industries comprise the manufacture of machinery, liqueurs, and spodium or tutty, the refining of naphtha, corn-milling, and the sawing of timber. The trade is chiefly in timber, corn, leather, and linen. Population (1890), 35,209; (1900), 46,349.

Pskoff, a government of north-west Russia, lying to the south of St Petersburg. It has an area of 17,069 square miles, and a population of 895,710 in 1881 and of 1,136,540 in 1897, when there were 584,931 women in the province, and the urban population numbered only 72,623. With the exception of some 10,000 Esthonians, the inhabitants are almost entirely Great Russians. They mainly belong to the Greek Orthodox Church, but Nonconformity is widely spread, the official number of Nonconformists, 32,066, being far below the mark. There are also about 12,000 Lutherans and 4000 Catholics. The government is divided into eight districts, the chief towns of which are Pskoff (see below), Kholm (5899 inhabitants), Novorzheff (2847), Opochka (5658), Ostroff (6252), Porkhoff (5573), Toropets (7489), and Velikiya Luki (8481). There were in 1896 only 518 schools, attended by 22,601 boys and 6236 girls. In 1887 the peasantry owned 4,114,400 acres of land, and 5,312,000 acres belonged to private owners, 366,100 acres to the Crown, 108,200 acres to the clergy, and 78,000 to various institutions. Since that time the conditions have considerably changed; between 1875 and 1896 the peasantry increased their possessions by 91 per cent., and the merchants bought considerable areas from the nobles, who altogether sold 43 per cent. of their estates. Although the soil is far from fertile, no less than 3,670,600 acres were under crops in 1900, and 1,359,600 acres were under meadows; the average annual yield from 1895 to 1899 was 97,000 cwt. of wheat, 4,003,000 cwt. of rye, 1,963,000 cwt. of oats, 756,000 cwt. of barley, and 4,160,000 cwt. of potatoes. Grain has to be imported, but oats are exported. Owing to the efforts of the *zemstvos*, there has been a notable improvement in agriculture, especially as regards dairy-farming. Flax is an important crop, producing on an average 86,200 quarters of linseed and about 48,000 tons of flax annually. Live stock in 1897 included 190,090 horses, 412,220 horned cattle, and 328,700 sheep. Fishing in Lake Pskov and the smaller lakes is a source of income, yielding about £40,000 annually. The manufacture of wooden goods for local needs, shipbuilding, the timber trade, and the weaving of linen and woollens for local requirements are additional sources of income; but factories are few, giving employment to less than 10,000 persons, and having an annual output valued at about £1,000,000.

Pskoff, the capital of the above government, situated on Velikaya river, 171 miles by rail south-west of St Petersburg. It has a lyceum for boys and another for girls, a cadets' school, a normal school for teachers, and a few lower technical schools, attended in 1896 by 2344 boys and 1138 girls, as also a few scientific societies. Its industries are insignificant, and its chief trade is in flax. In 1897 it had a population of 30,424.

Psychical Research.—"Psychical research" may be defined, partially, as an examination into the amount of truth contained in world-wide superstitions. Thus when Saul disguised himself, before his seance with the Witch of Endor, and when Crœsus scientifically tested the oracles of Greece (finding clairvoyance or *lucidité* in the Delphic Pythoness), Saul and Crœsus were psychical researchers. A more systematic student was the Neo-platonist philosopher Porphyry. In his letter to Anebo, answered by Iamblichus, we find Porphyry concerned with the usual alleged phenomena—prophecy; the power of walking through fire unharmed; the movements of inanimate objects, untouched; the "levitation" of "mediums"; apparitions of spirits, their replies to questions, the falsehood of those replies; and so forth. Similar phenomena fill the lives of the saints, and the records of witch trials. Apparitions, especially of the dying or the dead; the stereotyped disturbances in haunted houses; and the miraculous healing of diseases, are current in classical and mediæval records. The exhibition of remote or even future events, to gazers in mirrors, crystals, vessels full of water, or drops of ink or blood, are equally notorious in classical, Oriental, mediæval, and modern literature, while the whole range of these phenomena is found in Chinese, Japanese, Hindu, ancient American, Red Indian, and savage belief.

At various periods, and in proportion to the scientific methods of the ages, attempts have been made to examine these things scientifically. St Augustine wrote on the whole topic with remarkable acuteness and considerable scepticism; his treatment of miracles of healing is especially noteworthy. After Thyræus, S. J. Wierus, Lavater, and other authors of the 16th century, came the labours of Glanvil, Henry More, Richard Baxter, Boyle, Cotton Mather, and others in England and America, during and after the Restoration. Attempts were made to get first-hand evidence, and Glanvil investigated the Knocking Drummer of Tedworth *in situ* (1663). The disturbances in the house of the Wesleys at Epworth (1716 and later) were famous, and have copious contemporary record. David Hume believed himself to have settled questions which, when revived by the case of Swedenborg and the experiments of Mesmer and his pupils, puzzled and interested Kant. The influence of Mesmer has never died out; the fact of "animal magnetism" (with such examples as the "divining rod," and the phenomena in general) was accepted, in his manner, and explained, by Hegel. The researches of Braid (*circa* 1840–50) gave a new name, "hypnotism," to what had been called "mesmerism" or "animal magnetism," a name conveying no theory of "magnetic" or other "fluids." "Mesmerism" implies a theory of "emanations" from the operator to the patient; "hypnotism" implies no such hypothesis. In the middle of the 19th century Dr Gregory and Dr Mayo published their entertaining but unsystematic works on *Animal Magnetism* and *The*

Truths in Popular Superstitions. Esdaile and Elliotson were practical pioneers. The epidemic of "spiritualism" and of "turning tables" then invaded Europe from America, and was discussed by Dr Carpenter, Faraday, Gasparin, De Morgan, and many others. The adventures of Daniel Dunglas Home excited all Europe, and his effects were studied by Sir William Crookes with especial attention. Home disappeared after a law-suit; his arts seemed to have induced a wealthy widow to endow him with funds which a jury obliged him to restore. His successes remain an unsolved enigma. Believers explained them by the agency of the spirits of the dead, the old savage theory. He had many followers, most of whom, if not all, were detected in vulgar impostures. Of the books of this period those of Mr Richard Dale Owen are the most curious, but exact method was still to seek.

In 1882 the Society for Psychical Research, under the presidency of the late Mr Henry Sidgwick, professor of moral philosophy in the University of Cambridge, was founded, expressly for the purpose of introducing scientific method into the study of the "debatable phenomena." Other early members were the late Mr Edmund Gurney, the late Mr F. W. H. Myers, Professor Barrett, Mrs Sidgwick, Mr Podmore, Lord Tennyson, Lord Rayleigh, and Professor Adams, while among presidents were Professor Balfour Stewart, Mr A. J. Balfour, Professor William James of Harvard, and Sir William Crookes. The society has published many volumes of *Proceedings;* it has an American branch; in France is L'Institut Psychologique; and in Germany and Italy many men of distinguished scientific position have examined the Italian "medium" Eusapia, and have contributed experiments, chiefly in the field of hypnotism and "telepathy." That study has been introduced into official experimental psychology and medicine with some success.

It is plain that the range of psychical research is almost unlimited. It impinges on anthropology (with its study of the savage theory of spirits—animism—and of diabolical possession), and on the usual province of psychology, in the problems of the hallucinations both of morbid patients and of people in normal mental health. The whole topic of the unconscious or subconscious self is made matter not of mere metaphysical speculation (as by Kant and Hamilton), but of exact observation, and, by aid of hypnotism and automatism, of direct experiment. The six original committees of the society undertook the following themes:—

1. An examination of the nature and extent of any influence which may be exerted by one mind upon another, apart from any generally recognized mode of perception.
2. The study of hypnotism and the forms of so-called mesmeric trance, clairvoyance, and other allied phenomena.
3. A critical revision of Reichenbach's researches into certain organizations called "sensitive."
4. A careful investigation of any reports, resting on strong testimony, regarding apparitions at the moment of death or otherwise, or regarding disturbances in houses reputed to be haunted.
5. An inquiry into the various physical phenomena commonly called spiritualistic, with an attempt to discover their causes and general laws.
6. The collection and collation of existing materials bearing on the history of these subjects.

To these themes we might now add the study of "crystal gazing," and of the hallucinatory visions which a fair percentage of people observe when staring into any clear deep, usually a glass ball; but ink (with some experimenters) does as well, or a glass water-jug. Of these themes, the third has practically led to nothing. The experiments of Reichenbach on the perception of flames issuing from magnets have not been verified, though quite recently a hopeful case is reported. The collection of historical examples, again (6), has not been much pursued by the society, except in Mr Gurney's studies of witchcraft in *Phantasms of the Living*, by himself, Mr Podmore, and Mr Myers. On the other hand, a vast number of experiments were made in "thought transference." (1) Diagrams drawn by A were reproduced by B; cards thought of, numbers, and so forth, were also reproduced in conditions that appeared to make the normal transference of the idea by sound, sight, or touch impossible, and to put chance coincidence out of court. In one or two instances collusion was detected ingeniously. In others two explanatory theories have been broached. People may accidentally coincide in their choice of diagrams, or the "unconscious whispering" of a person fixing his mind hard on a number, card, or what not may be heard or seen. But coincidence in diagrams does not apply when a ship, dumb-bells, a candlestick, or a cat is drawn by both experimenters; nor can "unconscious whispering" be heard or seen when the experimenters are in different rooms. On the whole, the inquirers convinced themselves that one mind or brain may influence another mind or brain through no recognized channel of sense. This is, of course, an old idea (see Walton's *Life of Donne*, and his theory of the appearance of Mrs Donne, with a dead baby, to Dr Donne in Paris). The method of communication remains a problem. Are there "brain waves," analogous to the X-rays, from brain to recipient brain, or does mind touch mind in some unheard-of way? The former appears to be the hypothesis preferred by Sir William Crookes and Professor Flournoy (*Des Indes à la Planète Mars*, pp. 363–365). On this showing there is nothing "supranormal" in "telepathy," as it is called. The latter theory of "a purely spiritual communication" is argued for by Mr Myers (*Proceedings of the Society for Psychical Research*, vol. xv. pp. 407–410). If we accept telepathy as experimentally demonstrated, and regard it as a *physical* process, we reduce (4), "apparitions at the moment of death or otherwise," to a normal though not very usual fact. Every one would admit this in the case of mere empty hallucinations. A, in Paisley, sees P, in London, present in his room. P is neither dying nor in any other crisis, and A is, as both continue to be, in his normal health. Such experiences are by no means very uncommon, when there is nothing to suggest that P has exercised any telepathic influence on A. On the other hand, in *Phantasms of the Living*, and in the Report on the Census of Hallucinations (*Proceedings*, vol. x.), the society has published large numbers of "coincidental" hallucinations, the appearance of P to A coinciding with the death or other crisis of the distant P. That such "wraiths" do occur is the popular and savage belief. But, it may be urged, many hallucinations occur and many deaths. People only remember the hallucinations which happened, or were made by erroneous reckoning to seem to happen, coincidentally with the decease of the person seen. This is not quite true, for a hallucination so vivid as to be taken for a real person, and addressed as such, is not easily forgotten by a sober citizen, even if "nothing happened" afterwards. None the less, the coincidental hallucinations have certainly a better chance of being remembered, while fancy is apt to exaggerate the closeness of the coincidence. Nothing can demonstrate that coincidences between death and hallucination occur more frequently than by the doctrine of chance they ought to do, except a census of the whole population. In the present indifference of Government to psychical science

no party is likely to institute such a census, and even if it were done, the frivolity of mankind would throw doubt on the statistics. It would be necessary to cross-examine each "percipient," and to ask for documentary or other corroborative evidence in each case.

The Society for Psychical Research collected statistics in proportion to its resources. More than 17,000 answers were received to questions rather widely circulated. The affirmative respondents were examined closely, their mental and physical health and circumstances were inquired into, and collectors of evidence were especially enjoined to avoid selecting persons likely to return affirmative replies. There were eighty cases at first hand in which the death of the person seen coincided, within twelve hours, with the visual hallucination of his or her presence, out of 352 instances of such hallucinations. By way of arriving at the true proportions, the hallucinations which coincided with nothing were multiplied by four. In this way allowance was made for obliviousness of non-coincidental hallucinations. The verdict of the committee was that, on the evidence before them, hallucinations coincided with deaths in a ratio of 440 times more than was to be expected by the law of probabilities. The committee came to the conclusion that a relation of cause and effect does exist between the death of A and the vision of A beheld by P. The hallucination is apparently caused from without by some unexplained action of the mind or brain of A on the brain or mind of P. This effect is also traced, where death does not occur, for example, in the many instances of false "arrivals." A is on his way to X, or is dreaming that he is on his way, and is seen at X by P, or by P, Q, and R, as may happen. These cases are common, and were explained, in Celtic philosophy, by the theory of the "Co-Walker," a kind of "astral body." The facts are accounted for in the same way by Scandinavian popular philosophy. Doubtless in many instances such hallucinations are the result of expectancy in the beholder. Where the arrival is not expected, this explanation fails. In "second sight," even among savages, these occurrences are not infrequent, and doubtless admit of an explanation by telepathy. In two instances, known at first hand to the present writer, persons dreamed, at a distance, that they entered their own homes. In one the person was seen, in the other distinctly heard, by the inmates of his or her house. In several of these examples knocks are heard, as in spiritualist seances. In fact, if we accept the evidence, living but remote persons may, unconsciously, produce effects of sound and of phantasms exactly like those which popular belief ascribes to the spirits of the dead.

If we admit the evidence, of which a great body exists, and if we attribute the phenomena to telepathy, curious inferences may be drawn. Thus if the phenomena are such as only the spirits of the dead could be credited with producing—if the dead were frequently recognized by various good witnesses—it would follow (on the hypothesis of telepathy) that telepathy is not a *physical* process caused by material waves or rays from living brain to brain, the dead having no brains in working order. On the other hand, if living brains may thus affect each other, the subjective hallucination of the living A may conceivably be "wired on" to the living P. Thus A, in a given house, may have a mere subjective hallucination of the presence of the dead P, and may, unconsciously, infect with that hallucination other persons who come to the house. Thus once admit that any living brain may infect any other, and it becomes practically impossible for a spirit of the dead to prove his identity. Any information which he may give in any way must either be known to living people, however remote, or unknown. If known to a living person, he may, unconsciously, "wire it on" to the seer. If wholly unknown to everybody, the veracity of the information cannot be demonstrated, except later, when it refers to the unknown future. Thus the theory of telepathy, with a little goodwill, puts the existence and activity of the souls of the dead beyond possibility of proof.

These remarks apply to the researches of the society into alleged isolated phantasms of the dead, and into "haunted houses." As to the former cases, it is admitted on all hands that sane and sober people may have subjective hallucinations of the presence of living friends, not dying or in any other crisis. Obviously, then, the appearance of a dead person may equally be an empty hallucination. Thus, a member of the House of Commons, standing at the entrance of a certain committee-room, saw another member, of peculiar aspect and gait, pass him and enter the room, his favourite haunt. Several hours passed before the percipient suddenly recollected that the other member had been dead for some months. Even superstition cannot argue that this appearance was a ghost. In the same way Hawthorne, the celebrated novelist, frequently saw a dead club-man in his club. But suppose, for the sake of argument, that at intervals members of the House kept seeing these appearances of dead Members of Parliament, and suppose that they had never seen the prototypes in their lifetime, but yet correctly described them: then it might be said that their hallucinations had merely been "wired on" from the brain of some living Member of Parliament who knew the deceased.

Thus telepathy cuts two ways. It is, if accepted, a singular discovery, but it throws an enormous burden of proof on a "ghost" who wants to establish his identity. In the same way telepathy cuts at the root of "clairvoyance," or lucid view of events remote in space or distant in time. The vision may have been "wired on" telepathically by a living person who knew the remote event. The "supranormal" can only be proved if the information conveyed by the hallucination is verified in the future, or is proved by the finding of documents not known to exist at the time of the hallucination, but afterwards discovered. A curious possible instance was the discovery, in 1856, of a MS. inventory of the jewels of Mary Stuart (1566), verifying in some degree a clairvoyant vision about the jewels published some years earlier (see "Queen Mary's Jewels" in the writer's *Book of Dreams and Ghosts*). For the same reasons, the information nominally given by "spirits" of the dead through the mouth or by the automatic writing of Mrs Piper (Boston, U.S.) and other mediums may be explained by telepathy from the living who know the facts. This theory is rejected, for example in the case of Mrs Piper, by Mr Myers and Dr Hodgson, who have devoted much time to the examination of the lady (see *Proceedings*, vols. vi., viii., xiii., xiv., with criticisms by Mrs Sidgwick and the present writer in vol. xv. part xxxvi.). In Dr Hodgson's present opinion, the dead do communicate through the automatic writing or speaking of Mrs Piper. The published evidence (much is unpublished) does not seem to justify the conclusion, which is not accepted by Mrs Piper herself!

This leads us to the chief field of research in "automatisms," or actions of the subconscious or "subliminal" self. The prototype of such things is found in the performances of natural somnambulists, who in all ages have seemed to exhibit faculties beyond their power when in a normal condition. The experiments of Mesmer, and of those who followed in his track, down to the psychologists of to-day, proved (what had long been known to savages and conjurers) that a state of somnambulism could be induced from without. Moreover, it is proved that certain persons can, as it were, hypnotize themselves and pass into

trance. In these *secondary* conditions of trance, such persons are not only amenable to "suggestion," but occasionally evolve what are called secondary personalities: they speak in voices not their own, and exhibit traits of character not theirs, but in harmony with the impersonation. The popular, savage, and ancient theory of these phenomena was that the people thus affected were inspired by a god or spirit, or "possessed" by a demon or a dead man. Science now regards the gods or demons or spirits as mere exhibitions of the secondary personality, which wakens when the normal personality slumbers. The knowledge and faculties of the secondary personality, far exceeding those exhibited in the normal state, are explained to a great extent by the patient's command, when in the secondary state, of resources latent in the memory. The same explanation is offered for other phenomena, like those of automatic writing, knocking out answers by tilting tables, or discovering objects by aid of the "divining-rod." The muscular actions that tilt the table, or wag the rod, or direct the pencil or planchette, are unconsciously made, and reveal the latent stores of subconscious knowledge, so that a man writes or knocks out information which he possessed, but did not suspect himself of possessing. These processes were familiar to the Neoplatonists, and in one form or other are practised by Chinese, Tibetans, Negroes, Malayans, and Melanesians. A similar kind of automatism is revealed in the inspirations of genius, which often astonish the author or artist himself. An interesting example has been studied by Mr Myers in the feats of arithmetic recorded about "calculating boys," who are usually unconscious of their methods. The whole of this vast field of the unconscious, or subconscious, or subliminal self has been especially examined by Mr Myers, and by such psychologists as Ribot, Janet Richet, and many others.

The general result is a normal explanation, not yet complete, of the phenomena hitherto attributed to witchcraft, inspiration, possession, and so forth. Probably the devils, saints, angels, and spirits who have communicated with witches, living saints, demoniacs, and visionaries are mere hallucinatory reflections from the subconscious self, endowed with its store of latent memories and strangely acute percipient faculties. Thus a curious chapter of human history is at last within possible reach of explanation. Men regard phenomena as "supranormal" or "supernatural," or reject them altogether, till their *modus* is explained. But it would not be candid to say that the explanation is complete, or nearly complete. The nature of the hypnotic trance itself remains matter of dispute. The knowledge automatically revealed can by no means always be accounted for, either by latent memory or by the sharpening of the normal faculties of perception, while the limits of telepathy (if it be accepted) are vaguely conjectured. Even the results of simple experiments in "crystal-gazing" are often very perplexing. In all ages and countries it has been believed that certain persons can see visions in water, glass, ink, and polished surfaces generally. Experiment has proved, beyond the possibility of doubt, that this is actually the case. But when the visions are not mere fancy pictures, but correctly represent remote persons and events, unknown to the gazer, and perhaps unknown to all present, but later (in the case of the events) verified, the explanation is rather to seek. Further experiment may reveal some normal explanation, while scepticism (which seldom takes the trouble to examine the alleged facts with any care) can always repose on a theory of malobservation and imposture. These, of course, are *veræ causæ*, while in this, as in all provinces of human evidence, bad memories and unconscious errors distort the testimony. Psychical research encourages, or ought to encourage, the cool impartiality in examining, collecting, and recording facts, which is usually absent, in greater or less degree, from the work even of eminent historians. Men of equal honesty and acuteness may believe or disbelieve in the innocence of Mary Queen of Scots, or in the "spirits" which control Mrs Piper. As to alleged "physical phenomena" of unknown nature, one, the power of passing without lesion with naked feet over fire, has recently been attested by numerous competent observers and experimenters in the ritual of Fijians and other South Sea Islanders, Japanese, Bulgarians, natives of southern India, and other races. (The evidence has been collected by the present writer in *Proceedings S.P.R.* vol. xv. part xxxvi. pp. 2–15. Compare a case examined and explained, more or less, by Mr S. P. Langley, *Nature*, August 22, 1901.) The much more famous tales of movements of objects untouched have been carefully examined, and perhaps in no instance have professional performers proved innocent of fraud. Yet the best known living medium, Eusapia Paladino, though exposed at Cambridge, has been rehabilitated, after later experiments, in the opinion of many distinguished Continental observers, who entirely disbelieve in the old theory, the action of "spirits," and venture no other hypothesis.

The results of psychical research, after several years of work, are not really less than could be expected from toil in a field so difficult. The theory of alternating, or secondary, personalities is the key, as we have said, to a strange chapter in "The History of Human Error." The provisional hypothesis of telepathy puts a meaning into the innumerable tales of "wraiths" and of "second sight." It is never waste of time to investigate the area of human faculty; and practical results, in the medical treatment of abnormal intellectual conditions, have already been obtained. The conduct of our witch-burning ancestors now becomes intelligible, a step on the way to being pardonable. With their methods and inherited prejudices, they could scarcely have reasoned otherwise than they did in certain cases of hysteria and autohypnotization. Many "miracles" of healing, and of "stigmatization," become credible when verified in modern experience and explained by "suggestion"; though to "explain the explanation" is a task for the future. Such as it is, the theory was accepted by St Francis de Sales in the case of St Theresa. Results of wider range and of more momentous interest may yet be obtained. The science of electrical phenomena was not developed in a quarter of a century, and it would be premature to ask more from psychical research than it has achieved in a shorter period. The subject is not readily capable of exact experiment, human faculty being, as it were, capricious, when compared with ordinary physical processes. Imposture, conscious or unconscious, is also an element of difficulty. But already phenomena which are copiously reported throughout the whole course of history have been proved to possess an actual basis in fact, have been classified, and to some extent have been explained. Even if no light is ever to be cast on spiritual problems, at least the field of psychology has been extended.

The literature of psychical research is already considerable, and a complete bibliography would occupy much space. Readers who care to pursue the study will find their best guide in the *Proceedings* of the Society for Psychical Research, which contain a catalogue of the society's collection, including the Gurney Library (Hypnotism), with reviews of modern books in many languages—French, German, Italian, Russian—as they appear. Among modern English books may be recommended *Phantasms of the Living*, by Messrs Gurney, Podmore, and Myers; *Studies in Psychical Research*, by Mr Podmore, with his *Apparitions and Thought-Transference*; and *Principles*

of Psychology, by Professor William James, of Harvard. The historical side of the subject, especially as regards the beliefs of savages and of classical antiquity, may be studied in Mr E. B. Tylor's *Primitive Culture* (under "Animism"), in Mr Myers's *Classical Essays* (under "Greek Oracles"), and in the present writer's *Cock Lane and Common Sense*, and *Making of Religion*. Mr Myers's work, *Human Personality*, contains collections of facts, with a provisional theory. M. Th. Flournoy's *Des Indes à la Planète Mars* is a penetrating study of pseudo-spiritual "messages." A criticism making against the notion of telepathy may be found in Herr Parish's *Hallucinations and Illusions* (English translation). Some errors and confusions in this work (due in part to the expansion of the original text) are noted in the author's *Making of Religion*, Appendix A. (A. L.)

PSYCHOLOGY.

The science of Psychology has made unwonted strides since 1885. First of all, it has entered upon an experimental stage, and a well-equipped laboratory is now an adjunct of almost every important psychological school. A bewildering mass of detail has been accumulated relating to such processes as sensation, perception, memory, association, and attention (see PHYSIOLOGY, *Special Senses*). But there must be a thorough scrutiny of methods and a careful elimination of such results as have really only a physiological import, before we can decide how much of this material can be safely or systematically incorporated into the science itself. In the next place—and largely through the influence of Darwin—we have now the beginning of a new Comparative Psychology to replace the old repertories of anecdote collected by uncritical admirers of animal instinct and intelligence. Further, important additions to our psychological knowledge have resulted from the observations of the mental physician, particularly in cases of aphasia and cognate diseases, and in hypnotic and other abnormal states.

So impressive altogether are these extensions of psychology by objective methods of experiment and observation, that the older and more fundamental method of introspective reflection is nowadays often scouted not merely as more difficult—this has always been acknowledged—but as now at length altogether obsolete and superfluous. Thus, whereas the old psychology was closely related to the philosophical or moral sciences and sharply contrasted with the natural sciences, the new assumes very much the position long ago assigned to psychology by Comte: it becomes "mental physiology" or "physiological psychology." The distinction of natural and moral science only serves, on this view, to mark different stages of evolutional complexity: it ceases to be a distinction of kind.

But meanwhile, and from another side, the old psychology still shows signs of life. Here, too, great progress has been made, and several new lines of advance may be distinguished. The relation of psychology to epistemology, for example, has been very much under discussion of late. A generation ago it was common—except in Germany—to lump psychology and philosophy together under the common title of Mental Philosophy or Metaphysics.[1] Since then the growth of physiological psychology on the one hand, and the increasing influence of the Kantian philosophy on the other, have led to the undue severance of the two subjects, which is now in course of correction. But the psychologist no longer essays to solve the problem of objective knowledge by looking—after Locke's fashion—into the individual mind. Nowadays it is the epistemologist endeavouring to analyse and connect the forms, categories, and ideas (to use the Kantian phrases) by means of which objective knowledge is organized, who is led to demand, or perhaps himself to provide, a genetic psychology of Kant's *Bewusstsein überhaupt*—*i.e.*, of the general or collective mind, to which the universal and necessary syntheses of experience are referred.

To Kant at the close of the 18th century it seemed obvious that the so-called pure forms of knowledge and practice were original and ultimate faculties of the human mind, and therefore quite beyond elucidation by psychological methods, whether genetic or analytic. The hard and fast distinctions which he drew between *à priori* and *à posteriori*, between matter and form, cut off psychology from any part or lot in the deliberations of philosophy. But to Kant's followers at the opening of the 20th century it seems equally obvious, (1) that if the human mind is the result not of a special creation but of a continuous development, it cannot be, as he maintained, "perfectly futile labour" to investigate how those epistemologically *à priori* or transcendental forms were acquired; and (2) that, if acquired, those forms cannot be, as he supposed, elementary and ultimate in such wise as to render any analysis of them impossible. For the perceptual forms of space and time such analysis has been in the main accomplished already, and the result seems to entail important changes in the Kantian epistemology, especially in relation to mathematics.[2] As regards the categories, Kant's derivation of them from the forms of judgment is allowed to be little better than wasted ingenuity; while his admission of an *acquisitio originaria*, if not meaningless, brings them within the range of a genetic psychology dealing with objective experience, as our latter-day Kantians for the most part acknowledge.[3]

Again, two problems, that have vexed most philosophic thinkers since Descartes, are now brought into conjunction in a way that makes psychological revision inevitable: they are the question concerning the perception of an external world and the question as to the relation of body and mind. The solutions in vogue may be summarized as follows:—(1) "The face to face acquaintance with the real world which Common Sense assumes is illusory: the coloured, tangible, sonorous world is not the external world at all, not even a copy of it. Our sensations are but symbols or indications of external reality; the most we can say is that there is correspondence between the two." (2) "States of mind and states of brain run parallel, but do not interact: brain changes, both as to the causes that produce them and the effects that they produce, belong entirely to the physical world of matter and motion." The deadlock here becomes palpable and evident on a very slight examination. On the physical side it cannot be known that psychical changes shadow neural changes, for there can be no physical evidence that psychical change occurs at all. And on the psychical side, though one sensation may serve as index to another *sensation*, it is as impossible that sensory experience should give any clue to what is, *ex hypothesi*, wholly beyond it, as that sounds, for example, should apprise a blind man of colours or colours a deaf man of sounds. In fact, according to these theories the physical and the psychical standpoints are comparable to the positions of the blind and deaf relatively to each other. A way out of the difficulty is sought in a surreptitious use of the notion of causality. Sensations, it is assumed, are not merely indications, but effects, of the external world in the one case; and mental states generally are not merely concomitants, but "collateral," non-physical, products of neural states in the other. The justification of these assumptions must, in part at all events, be referred to psychology.

In this supplementary article the attempt will be made to discuss the various new topics just described, on the old lines as far as possible and as fully as the limits allow.

STANDPOINT; RELATION TO EPISTEMOLOGY; GENERAL ANALYSIS.

In defining psychology the propriety of avoiding the term *Mind*, on account of its implication of the disastrous dualism of mind and matter, is widely acknowledged. But the term *Consciousness*, which is the most frequent substitute, is liable to an opposite objection, that of laying undue stress on the subjective as opposed to the objective. Experience is, it is maintained, a more fundamental and less ambiguous conception. We must start, of course, from individual human experience; and we must endeavour from this standpoint to determine the "irreducible minimum" involved, so that our conception may apply to all lower forms of experience as well. Etymologically *experience* connotes practical acquaintance, efficiency, and skill as the result of trial—usually repeated trial—and effort. Many recent writers on comparative psychology propose to make evidence of experience in this sense the criterion of psychical life or "mentality." The ox knoweth his owner and the ass his master's crib, and so would pass muster; but the ant and the bee, who are said to learn nothing, would, in spite of their marvellous instinctive skill, be regarded as mere automata in Descartes' sense. That this criterion is decisive on the positive side will hardly be denied; the question how far it is available negatively we must examine later on. But it will be well first briefly to note some of the implications of this positive criterion: *Experience is the process of becoming expert by experiment.* The chief implication, no doubt, is that which in psychological language we express as the duality of subject and object, already strenuously insisted on in the article in the earlier volumes of this Encyclopaedia. Looking at this relation as the comparative psychologist has to do, we find that it tallies in the main with the biological relation of organism and environment. The individuality of the organism corresponds to, though it is not necessarily identical with, the psychological subject, while to the environment and its changes corresponds the objective *continuum* or *totum objectivum* already described (p. 45).[1] This correspondence further helps us to see still more clearly the error of regarding individual experience as wholly subjective, and at the same time helps us to find some measure of truth in the naïve realism of Common Sense. As these points have an important bearing on the connexion of psychology and epistemology, we may attempt to elucidate them more fully. Though it would be unwarrantable to resolve a *thing*, as some have done, into a mere meeting-point of relations, yet it is perhaps as great a mistake to assume that it can be anything determinate in itself apart from all relations to other things. By the physicist this mistake can hardly be made: for him action and reaction are strictly correlative: a material system can do no work on itself. For the biologist, again, organism and environment are invariably complementary. But in psychology, when presentations are regarded as subjective modifications, we have this mistake in a glaring form, and all the hopeless difficulties of what is called "subjective idealism" are the result. Subjective modifications no doubt are always one constituent of individual experience, but always as correlative to objective modifications or change in the objective *continuum*. If experience were throughout subjective, not merely would the term subjective itself be meaningless, not merely would the conception of the objective never arise, but the entirely impersonal and intransitive process that remained, though it might be described as absolute becoming, could not be called even solipsism, least of all real experience. Common Sense, then, is right in positing, wherever experience is inferred, (1) a factor answering to what we know as self, and (2) another factor answering to what each of us knows as the world. It is further right in regarding the world which each one immediately knows as a coloured, sounding, tangible world, more exactly as a world of sensible qualities. The assumption of naive realism, that the world as each one knows it exists independently of him, is questionable. But this assumption goes beyond individual experience, and does not, indeed could not, arise at this standpoint.

There is one further characteristic of individual experience involved in the preceding that is worth noting here. Answering to the individuality and unity of the subjective factor, there is a corresponding unity and individuality of the objective. Every Ego has its correlative Non-Ego, whence in the end such familiar sayings as *Tot mentes quot sententiæ*, and the like. The doctrine of Leibnitz, that "each monad is a living mirror . . . representative of the universe according to its point of view," will, with obvious reservations, occur to many as illustrative here. In particular, Leibnitz emphasized one point on which psychology will do well to insist. "Since the world is a plenum," he begins, "all things are connected together, and every body acts upon every other, more or less, according to their distance, and is affected by their reaction; hence each monad is a living mirror," &c.[2] Subject and Object, or (as it will be clearer in this connexion to say) Ego and Non-Ego, are then not merely logically a universe, but actually *the universe*, so that, as Leibnitz put it, "He who sees all could read in each that which passes everywhere else" (*Monadology*, § 61). Though every individual experience is unique, yet the more Ego_1 is similar to Ego_2 the more their complementaries $Non\text{-}Ego_1$, $Non\text{-}Ego_2$ are likewise similar; much as two perspective projections are more similar the more adjacent their points of sight, and more similar as regards a given position the greater its distance from both points. No doubt we must also make a very extensive use of the hypothesis of subconsciousness, just as Leibnitz did, before we can say that *the universe* is the objective factor in each and every individual's experience. But we have in any case to allow that, besides the strictly limited "content" rising above the threshold of consciousness, there is an indefinite extension of the presentational *continuum* beyond it. And the Leibnitzian Monadology helps us also to clear up a certain confusion that besets terms such as "content of consciousness," or "finite centre of experience"—a barbarous but intelligible phrase that has recently appeared—the confusion, that is, with a mosaic of mutually exclusive areas, or with a scheme of mutually exclusive logical compartments. Consciousnesses, though in one respect mutually exclusive, do not limit each other in this fashion. For there is a sense in which all individual experiences are absolutely the same, though relatively different as to their point of view, *i.e.*, as to the manner in which for each the same absolute whole is sundered into subjective and objective factors.

This way of looking at the facts of mind helps, again, to dispel the obscurity infecting such terms as subjective, intersubjective, transsubjective, and objective, as these occur in psychological or epistemological discussions. For the psychologist must maintain that no experience is merely subjective: it is only epistemologists, and notably Kant, who so describe individual experience, because for them objects experienced in their concrete particularity pertain, like so many idiosyncrasies, to the individual alone. In contrast with this, epistemologists then describe universal

[1] References to pages in the text without further qualification are to pages of the earlier article in this Encyclopædia, vol. xx. (ninth edition).

[2] *Principles of Nature and Grace*, § 3.

experience, the objects in which are the same for every experient, as objective experience *par excellence*. And so has arisen the time-honoured opposition of Sense-knowledge and Thought-knowledge: so too has arisen the dualism of Empiricism and Rationalism, which Kant sought to surmount by logical analysis. It is in the endeavour to supplement this analysis by a psychological genesis that the terms intersubjective and transsubjective prove useful. The problem for psychology is to ascertain the successive stages in the advance from the one form of experience or knowledge to the other. "When ten men look at the sun or the moon," said Reid, "they all see the same individual object." But according to Hamilton this statement is not "philosophically correct, . . . the truth is that each of these persons sees a different object. . . . It is not by perception but by a process of reasoning that we connect the objects of sense with existences beyond the sphere of immediate knowledge."[1] Now it is to this "beyond" that the term *transsubjective* is applied, and the question before us is: How do individual subjects thus get *beyond* the immanence or immediacy with which all experience begins? By a "process of reasoning," it is said. But it is at least true in fact, whether necessarily true or not, that such reasoning is the result of social intercourse. Further, it will be generally allowed that Kant's *Analytik*, before referred to, has made plain the insufficiency of merely formal reasoning to yield the categories of Substance, Cause, and End, by which we pass from mere perceptual experience to that wider experience which transcends it. And psychology, again, may claim to have shown that in fact these categories are the result of that reflective self-consciousness to which social intercourse first gives rise (cf. pp. 75 n^1, 84).

But such intercourse, it has been urged, presupposes the common ground between subject and subject which it is meant to explain. How, it is asked, if every subject is confined to his own unique experience, does this intersubjective intercourse ever arise? This objection—formidable though it seems when the discrete alternatives, "either . . . or," are alone considered as in logical analysis[2]—disappears in the region of continuous development with which genetic psychology deals. If *no* progress towards intellective synthesis were possible before intersubjective intercourse began, such intercourse, as presupposing something more than immediate sense-knowledge, obviously never could begin.[3] Let us illustrate by an analogy which Leibnitz's association of experience with a "point of view" at once suggests. If it were possible for the terrestrial astronomer to obtain observations of the heavens from astronomers in the neighbouring stars, he would be able to map in three dimensions constellations which now he can only represent in two. But unless he had ascertained unaided the heliocentric parallax of those neighbouring stars, he would have no means of distinguishing them as near from the distant myriads besides, or of understanding the data he might receive; and unless he had first of all determined the still humbler geocentric parallax of our sun, those heliocentric parallaxes would have been unattainable. So in like manner we may say "intersubjective parallax" presupposes what we may call "subjective parallax," and even this the psychological duality of object and subject. But such subjective parallax or acquaintance with other like selves is the direct outcome of the extended range in time which memory proper secures; and when in this way self has become an object, resembling objects become other selves or "ejects," to adopt with slight modification a term originated by Professor W. K. Clifford. We may be quite sure that his faithful dog is as little of a solipsist as the noble savage whom he accompanies. Indeed, the rudiments of the social factor are, if we may judge by biological evidence, to be found very early. Sexual union in the physiological sense occurs in all but the lowest *Metazoa*, pairing and courtship are frequent among insects, while "among the cold-blooded fishes the battle of the stickleback with his rivals, his captivating manœuvres to lead the female to the nest which he has built, his mad dance of passion around her, and his subsequent jealous guarding of the nest, have often been observed and admired."[4] Among birds and mammals we find not merely that these psychological aspects of sexual life are greatly extended, but we find also prolonged education of offspring by parents and imitation of the parents by offspring. Even language, or at any rate "the linguistic impulse," is not wholly absent among brutes.[5] Thus as the sensorimotor adjustments of the organism to its environment *generally* advance in complexity and range, there is a concomitant advance in the variety and intimacy of its relations *specially* with individuals of its kind. It is therefore reasonable to assume no discontinuity between phases of experience that for the individual are merely objective and phases that are also ejective as well; and once the ejective level is attained, some interchange of experience is possible. So disappears the great gulf fixed betwixt subjective or individual and intersubjective or universal experience by rival systems in philosophy.

One other implication of the psychological conception of experience calls for brief mention, for it is one that of late years has gained many adherents. Experience as the psychologist deals with it, living experience, is primarily and pre-eminently practical. Obvious as this must appear to those who look at the facts of life in the light of the theory of evolution, yet it is a truth that was for the most part overlooked so long as psychology was studied mainly by philosophers, and studied therefore mainly in its bearing on philosophical problems. But the notion of an independent realm of truth existing *sub specie æternitatis* has literally no place within the purview of a psychology that knows its business. Here we find no such thing as mere cognition: the uninteresting is not known but ignored, and the interesting leads at once to response, and sooner or later to adjustment—in the race, at all events. Success is then completed experience or expertness, and in general prepares the way for a new advance. So far the true is the useful, and the criterion is not theoretical but practical. Looking broadly at the progress of life, as it ascends through the animal kingdom and onwards through the history of man, it seems safe to say that knowledge is always a means to ends, is never an end by itself—till at length it becomes interesting and satisfying in itself. Psychologically, then, the sole function of perception and intellection is to guide action and subserve volition—more generally, to promote self-conservation and betterment. Knowledge, from this point of view, may even be regarded as the joint product of natural selection and subjective selection: it emerges tainted, as some may think, at all events permeated, by a teleological colouring.[6]

Sensation, Movement, and the External World.

On the view of experience just described, we are led to challenge the physiological method of describing sensations as due to physical stimuli, which is still widely current. The following definition, given by Dr Bain, may be taken as a type:—"By sensations, in the strict meaning, we understand the mental impressions, feelings, or states of consciousness following on the action of external things on some part of the body, called on that account, sensitive."[7] It is true, no doubt, that what the psychologist calls sensibility has as its invariable concomitant what physiologists call sensibility, or what the more careful of them call irritability; and, true again, that this irritability is invariably preceded by a physical process called stimulation. But the converse statements are not true: there may be stimu-

[2] It is amazing how often this type of argument has occurred since Zeno's famous paradoxes about motion, where it first appears.

[3] And it is precisely for want of this mediation that Kant's "two stems of human knowledge, which *perhaps* may spring from a common but to us unknown root," leave epistemology still more or less hampered with the old dualism of sense and understanding.

James, *Philosophical Conceptions and Practical Results*, 1898; J. Ward, *Naturalism and Agnosticism*, 1899, vol. ii. pp. 133 f., 245 f., 253 f., &c. The view above described, which doubtless is substantially an indirect result of the philosophy of Schopenhauer, has been called Voluntarism (Paulsen, Wundt), and again Pragmatism (James).

[7] *Senses and Intellect*, 4th ed., 1894, p. 101.

lation and no consequent irritation, irritation and no concomitant sensation. It is then certain that the three processes are distinct, and it is equally certain that the last alone enters into immediate experience. Nevertheless, it is urged, why not recognize a connexion that actually obtains, since otherwise sensation must remain unexplained? Well, in the first place, such "psychophysical" connexion is not a psychological explanation: it cannot be turned directly to account in psychology, either analytic or genetic. Next, the psychological fact called sensation always is, and at bottom always must be, independently ascertained; for, as said, the physiological "neurosis" or irritation has not necessarily a concomitant "psychosis" or sensation and, strictly dealt with, affords no hint of such. Finally, this inexplicability of sensation is a psychological fact of the utmost moment: it answers to what we call reality in the primary sense of the term. The psychophysicist, in setting out to explain sensation, has—unawares to himself—left this fundamental reality behind him. For it belongs essentially to individual experience, and this—in assuming the physical standpoint—he has of course transcended. Nevertheless the mistake of method that here reveals itself was perhaps inevitable, for the facts of another's sense-organs and their physical excitants must have obtruded themselves on observation long before the reflective attitude was advanced enough to make strictly psychological analysis possible. The psychophysical standpoint, that is to say, was attained before the purely psychological; and the consequent bias is only now in process of correction. A series of physical processes, first without and then within the organism—ethereal or aërial vibrations, neural and cerebral excitations—was the starting-point. What comes first, immediately, and alone, in the individual's experience, and is there simply and positively *real*, was then misinterpreted as subjective modification, mental impression, *species sensibilis*, or the like. For from the days of Democritus down to our own the same crude metaphor has prevailed without essential variation. And here the saying holds: *Nulla vestigia retrorsum.* Into the man's head the whole world goes, including the head itself. Such thoroughgoing "introjection" affords no ground for subsequent "projection." Thus the endeavour to explain sensation overreaches itself: the external object or thing that was supposed to cause sensations, and to be therefore distinct from them, was in the end wholly resolved into these and regarded as built out of them by association (Mill) or by apperceptive synthesis (Kant). But no "mental chemistry," no initial alchemy of "forms," can generate objective reality from feelings or sense-impressions as psychophysically defined.[1] A's experience as it is for B is not real but inferential; and if the grounds of the inference, which are realities only for B, are to be regarded as the causes of which A's experiences are merely the effects, then the two experiences are on a wholly different footing. When A treats B in the same fashion we get the world in duplicate: (1) as original and outside, *i.e.*, as *cause*, and (2) as copied within each percipient's head, *i.e.*, as *effect*. But when B interprets his own experience as he had interpreted A's, we seem to have lost the real world altogether. In presence of this dilemma, the philosophers of our time, as already said, are feeling it needful to revise their psychology. The question of method is vital. If the psychophysical standpoint were the right one, psychology would be based on physiology, and the old conception of sensation might stand. If, on the other hand, it is the exclusive business of psychology to analyse and trace the development of individual experience as it is for the experiencing individual, then—however much neurological evidence may be employed as a means of ascertaining psychological facts—the facts themselves must be scrupulously divested of all physical implications, the psychophysical method takes a secondary place, and the objective reality of "sensory" presentations stands unimpeached.

Motor presentations have been constantly under discussion since 1875, and at length it may perhaps be said that clearer views begin to prevail. Auxilio-motor presentations (now called kinæsthetic), by means of which bodily equilibrium and locomotor *taxis* are regulated, were commonly allowed to be purely sensory, the concomitants of centripetal excitations: hence the older name of "muscular or sixth sense" applied to them by Sir Charles Bell, Weber, Sir William Hamilton, and others. But concerning motor presentations proper (more commonly called feelings of innervation or feelings of effort), the view first tentatively advanced by the great physiologist Johannes Müller, and adopted by Helmholtz, Wundt, and especially by Professor Bain, is now generally discredited, if not completely overthrown.[2] According to this view, "the characteristic feeling of exerted force" must be regarded, Dr Bain maintains, "not as arising from an inward transmission . . . . but as the concomitant of the *outgoing* current by which the muscles are stimulated to act" (*op. cit.*, p. 79).

The necessity for this assumption has certainly not been established on physiological grounds, nor apparently does Dr Bain rely primarily on these, for at the very outset of his discussion we find him saying "that action is a more intimate and inseparable property of our constitution than any of our sensations, and enters as a component part into every one of our senses" (*op. cit.*, p. 59). But this important psychological truth is affirmed as strenuously by some at any rate (*e.g.*, Prof. James) of Dr Bain's opponents as it is by Dr Bain himself. Unhappily many, under the same psychophysical bias and so induced, like the upholders of this innervation theory, to look for evidence of subjective activity in the wrong place, have been led to doubt or to deny the reality of this activity altogether. In fact, this theory, while it lasted, tended to sustain an undue separation of so-called "sensory" from so-called "motor" presentations, as if living experience were literally an alternation of two independent states, one wholly passive and the other wholly active, corresponding to the anatomical distinction of organs of sense and organs of movement. The subject of experience or Ego does not pass to and fro between a *sensorium commune* or intelligence department and a *motorium commune* or executive, is not in successive intervals receptive and active, still less always passive, but rather always actively *en rapport* with an active Non-Ego, commonly called the External World.

Experience at this level—experience, that is to say, confined to sensation and movement—may be described as perceptual, and as consisting of the differentiation and redintegration of a presentational continuum (cf. pp. 51 f.). Space and time, as "forms" of this perceptual experience, have, it is important to note, certain concrete characteristics not pertaining to the ideal conceptions of pure space and pure time afterwards elaborated from them. Both psychology and epistemology gain by the recognition of these differences, which, owing to the influence of Kant, have till recently been quite ignored. Only the barest reference to these characteristic differences is here possible.[3]

[1] Nothing shows this more plainly than the newly-coined term *epiphenomenon* now applied in this connexion. As to this, see below, p. 68.

[2] Cf. Bastian, *The Brain as an Organ of Mind*, 1880, pp. 691 ff.; Ferrier, *The Functions of the Brain*, 2nd ed., 1886, pp. 382 ff.; James, *Principles of Psychology*, 1890, ch. xxvi.

[3] Cf. Ward, *Naturalism and Agnosticism*, 1899, vol. ii. pp. 136–149, for fuller treatment.

(1) "Here" and "now" are for the individual percipient absolute positions, and have no counterpart in the thoroughgoing relativity of abstract space and time. (2) Again, they refer not to a mathematical "point" and "instant," but imply a certain "restricted ubiquity." This, in the case of space, answers to the primitive extensity of what may be called the body-sense, the fundamental importance of which for the further elaboration of spatial experience is now at length widely recognized.[1] In the case of time, such "ubiquity" answers to that "sensible present" or "enduring now," within which change is directly apprehended: the reduction of this to an instant would render experience impossible.[2] (3) In this perceptual experience of the temporal and spatial in the concrete there is nothing of that homogeneity which science attributes to space and time in the abstract. The "body-sense," in contrast with what may be called "the projecting senses,"[3] yields the vital distinction of internal and external, marking off the bodily self from its environment. The environing space, again, varies in character, intimacy, and even in dimensions as we recede from the foreground towards the background, from objects to which we can adjust by changes of posture to objects only to be reached by locomotion. A similar perspective is characteristic of temporal perceptions, but is confined almost entirely to the "psychical present" till experience advances to the ideational stage. To this stage we may now turn.

Growth and Development of Ideation.

We find ourselves sometimes engrossed in present perceptions, as when tracing, for example, the meanderings of an ant; at other times we may be equally absorbed in reminiscences; or, again, in pure reverie and "castle-building." Here are three well-marked forms of conscious life: the first being concerned with what is, the second with what has been, and the third with the merely possible. Again, the first involves definite spatial and temporal order, though the temporal order, as just said, is in the main restricted to the "sensible present"; the second involves only definite time-order; and the last neither in a definite way. Thus analytically regarded, perception, memory, imagination, show a steady advance. In infancy the first predominates, while senility lapses back to the second; in the third, where similarities suggest themselves and the contrast of actual and possible is explicit, we have at length the groundwork of logical comparison. Nevertheless, since imagination plays a conspicuous part in child-life before much personal reminiscence appears, it would seem probable that ideas do not first arise as definite memory-images or reminiscences. On the other hand, in the so-called homing instincts of the lower animals we have evidence of isolated "memories" of a simpler form than ours. Altogether it will be best, therefore, to lay aside the analytical distinction of a memory continuum or "thread," and of an ideational continuum or "texture"[4] (supposed to be formed by reduplication of the thread upon itself), in here taking up anew the question of the genesis of ideas, very inadequately dealt with in the earlier article (p. 60).

The subject is as difficult as it is interesting and important, and we can hardly hope at present for a final solution. One chief obstacle, as is so often the case in psychology, lies in the unsettled connotation of such leading terms as *memory*, *association*, and *idea*. Even what is most fundamental of all, that "plasticity" which we have analysed into retentiveness, differentiation, and integration, is sometimes described as if it already involved memory-ideas and their association. Ideas, that is to say, are identified with mere "residua" of former "impressions," and yet at the same time are spoken of as "copies" of these: which is much like saying the evening twilight is a *replica* of the noonday glare as well as its parting gleam. Again, the continuous differentiation and redintegration of the presentational continuum which mark the progress of perceptual experience are resolved into an original multiplicity of presentational atoms which are associated by "adhesion" of the contiguous. Yet before the differentiation there was no plurality, and after the integration there is only a complex unity, comparable perhaps with a group of segregated cells or other organic whole, but certainly not with a mosaic stuck together with cement. This mistaken identification by the Associationist psychology of later processes with simpler and earlier ones, by which they are only partially explained, has not only obscured the science with inappropriate conceptions but has prevented the question on which we are entering—that concerning the genesis and development of ideas—from being ever effectually raised. The discussion of this question will incidentally yield the best refutation of those views.

Experience, we say (cf. above, p. 56), is the acquisition of practical acquaintance and efficiency as the result of repeated opportunity and effort. This means that strangeness on the cognitive side gives place to familiarity, and that on the active side clumsiness is superseded by skill. But though analytically distinct, the two sides are, as we have already insisted, actually inseparable: to the uninteresting we are indifferent, and what does not call for active response is ignored. If the original presentations, whether sensory or motor, be A, B, C, we find then that they gradually acquire a new character, become, let us say, A^γ, B^γ, C^γ, γ representing the eventual familiarity or facility, as the case may be. We find, again, a certain sameness in this character, however various the presentations to which it pertains, a sameness which points to the presence of subjective constituents, and to these we may assign the "feelings" that enter into accommodation and adjustment. This factor is important as evidence of a subjective co-operation which may enable us to dispense with the mutual "adhesions" and "attractions" among presentations, on which the Associationists rely. But it is obvious that there must be an objective factor as well; and it is this objective factor in the process giving rise to γ that now primarily concerns us. We have described that process as assimilation or immediate recognition: the older psychology described it as association of the completely similar, or as automatic association. That the two views have something in common is shown by the juxtaposition of "automatic" and "immediate," "similarity" and "assimilation." To prepare the way for further discussion, let us first ascertain these points of agreement. "When I look at the full moon," says Dr Bain, "I am instantly impressed with the state arising from all my former impressions of her disc added together." This we may symbolize in the usual fashion as $A + a_n \cdot \cdot \cdot \cdot \cdot + a_3 + a_2 + a_1$. Now, it will be granted (1) that the present occurrence (full moon) has been preceded by a series of like occurrences, enumerable as 1, 2, 3, . . . n; (2) that the present experience (A^γ) is what it is in consequence of the preceding experiences of those occurrences; and (3) that it "arises instantly" as the joint result of such preceding experiences. But it is denied (1) that this present experience is the mere sum, or even the mere "fusion," of the experiences preceding it; or (2) that they were qualitatively identical; or (3) that they persist severally unaltered, in such wise that experience "drags at each remove a lengthening chain" of them. In the case of dexterities, where γ answers to facility, it is obvious that there is no such series of identicals (a_1, a_2, . . . a_n) at all. From the first rude beginning—say the schoolboy's pothooks—up to the finished performance of the adept there is continuous approximation: awkward

[1] Cf. especially James, *Principles of Psychology*, 1890, ch. xx.

[2] Cf. James, *op. cit.*, vol. i. pp. 608 ff.; L. W. Stern, "Psychische Präsenzzeit," *Zeitschrift f. Psychologie u.s.w.*, 1897, Bd. xiii. pp. 325 ff.

[3] For the suggestion of these terms see Flechsig, *Gehirn und Seele*, 1896, p. 21.

[4] Terms suggested, of course, by the Herbartian *Reihe* and *Gewebe*; cf. vol. xx. pp. 58 and 61.

and bungling attempts, passing gradually into the bold strokes of mastery. Nor is the case essentially different in cognition where γ answers to familiarity, if we attend, as it is plain we ought, not to the physical fact but to the individual's percept. This too is an acquisition, has entailed activity, and is marked by gradual approximation towards clearness and distinctness. The successive experience of n identical occurrences does not then result in an accumulation of n identical *residua*. The ineptness of the atomistic psychology with its "physical" and "chemical" analysis is nowhere more apparent than here. Considering the intimate relation of life and mind, and the strong physiological bias shown by the Associationists from Hartley onwards, it is surely extraordinary how completely they have failed to appreciate the light-bearing significance of the conceptions of function and development. Facility and faculty (or function) are much the same, both etymologically and actually. As the perfected structure is not so many rudimentary structures "added together," but something that supersedes them completely, must we not say the same of the perfected function? The less fit is not embodied in the fittest that finally survives. Development implies change of form in a continuous whole: every growth *into* means an equal growth *out of*: thus one cannot find the caterpillar in the butterfly. Between organic development and mental development there is then more than an analogy.

But though assimilation cannot be analysed into a series of identical ideas ($a_1, a_2, \cdot \cdot \cdot a_n$), either "added together" or "instantaneously fused," yet it does result in an a which may *provisionally* be called an idea. Such idea is, however, neither a memory-idea in the proper sense nor an idea within the meaning of the term implied in imagination or ideation. For it is devoid of the temporal-signs indicated by the subscript numerals in $a_1, a_2 \cdot \cdot \cdot$, and it does not yet admit of reproduction as part of an ideational continuum, one, that is, divested of the characteristics belonging to the actual and sensibly present. It is, so to say, embryonic, something additional to the mere sensation assimilated, and yet something less than a "free or independent idea." It is, as it has been happily called,[1] a tied (*gebundene*) or implicit idea. We have clear evidence of the sense-bound stage of this immature "idea" in the so-called "memory after-image" already described (pp. 59 f.). There is, however, nothing in this of memory, save as the term is loosely used for mere retentiveness; and *after-percept* would therefore be a less objectionable name for it. This after-percept is entirely sense-sustained and admits of no ideal recall, though—*in minds sufficiently advanced*—it may persist for a few moments, and so form the basis of such comparison with a second sensation as we find in the experiments of Weber, Fechner, and others.[2] At a still lower level, or in actual perception, we cannot assume even this amount of partial independence, though continuity clearly points to something beyond the bare sensation, which is a pure abstraction, as we may presently see.

It is saying too little to maintain, as some do, that this "something" is subconscious, on the ground that it is not discoverable by direct analysis. Yet it is saying too much, regardless of this defect, to describe a percept as a presentative-representative complex, if representation is to imply the presence of a free or independent idea. To call this "something" a tied or nascent idea on the ground of its possible later development into an independent representation seems, then, nearest the truth. The same meaning is sometimes expressed in a wholly different, and designedly paradoxical, way, by saying that all cognition (perception) is *recognition*. This statement has been met by elaborate expositions of the difference between knowing and knowing *again*, the irrelevance of which any lexicon would show; and, further, by the demand: How on such a view is a *first* cognition possible, or how is an indefinite regress of assimilation to be avoided? We may confidently reply that it cannot be avoided: an absolute beginning of experience, whether phylogenetically or ontogenetically, is beyond us. Assimilation means further assimilation; in this sense all cognition is further cognition, and a bare sensation is, as said, an abstraction representing a limit to which we can never regress.

We find evidence, again, of ideas in the making in what Lewes called preperception. Of this instances in plenty are furnished by everyday illusions, as when a scarecrow is hailed by the traveller who mistakes it for a husbandman, or when what is taken for an orange proves to be but an imitation in wax. In reality all complex percepts involve preperception; and so far, it must be allowed that such percepts are directly analysable into presentative-representative complexes. Nevertheless the representative element is not yet, and may never become, an idea proper. The sight of ice yields a forefeel of its coldness, the smell of baked meats a foretaste of their savour. Such prepercepts differ from free ideas just as after-percepts do: they are still sense-bound and sense-sustained (cf. p. 57). Nor can this complication be with any propriety identified either with the association pertaining to memory or with that specially pertaining to ideation; though, no doubt, the two processes—complication and association—are genetically continuous, as are their respective constituents, nascent and free ideas.[3] The whole course of perceptual integration being determined and sustained by subjective interest, involves from the outset, as we have seen, concurrent conative impulses; and thus the same assimilation that results in familiarity and preperception on the subjective side results in facility and purpose on the conative. Knowing immediately *what to do* is here the best evidence of knowing *what there is* to do with; the moth that flies into the candle has assuredly no preperception of it, and does not act with purpose. Bearing this in mind, we may now see one way, and probably the earliest, in which tied ideas become free.

The contrast between the actual and the possible constitutes, as we have seen, the main difference between experience at the perceptual and experience at the ideational stage. A subject confined to the former level knows not yet this difference. Such knowledge is attained not through any quasi-mechanical interaction of presentations, but usually through bitter experience. The chapter of accidents is the Bible of fools, it has been said; but we are all novices at first, and get wisdom chiefly by the method of trial and failure. Things are not always different in what to us are their essential properties, but they so differ from time to time. Resemblances are frequent enough to give us familiarity and confidence; yet uniformity is flecked by diversity, and thwarted intentions disclose possibilities for which we were not prepared. What was taken for sugar turns out to be salt; what was seized as booty proves to be bait. We catch many Tartars,

[1] Cf. Höffding, "Ueber Wiederkennen, Association und psychische Activität," in *Vierteljahrsschr. f. wissenschaftl. Philosophie*, Bd. xiii. and xiv. To Höffding we are also indebted for the term *Bekanntheitsqualität*, which has suggested the γ character used above. Cf. also Ward, "Assimilation and Association," *Mind*, 1894–95.

[2] Recent experiments, however, seem to prove that the after-percept is not the sole factor, and often is not a factor at all in such successive comparison (so-called); but that what is now termed "the absolute impression" may supplement it or even replace it altogether. As to what is meant by absolute impression, cf. earlier article, vol. xx. p. 50, col. *a*, *fin*.

[3] Hence the earlier process has been named "impressional association" (Stout, *Analytic Psychology*, 1896, ii. pp. 27–29), and again "animal association" (Thorndike, *Animal Intelligence, an Experimental Study of the Associative Processes in Animals*, 1898, pp. 71, 87, and *passim*). But it seems preferable to confine the term "association" to the later process, in which alone the component presentations have that amount of distinctness and individuality which the term properly connotes.

and so learn wariness in a rough school. In such wise preperceptions displaced by the actual fact yield the "what" severed from the "that," the "ideal" freed at length from the exclusive hold of the real. In a new situation after such adventures the attitude assumed—if, for brevity, we describe it in terms of our own still more advanced experience—is of this sort:—"It is possibly sugar, in which case I eat; possibly salt, and then I don't. It may be a weasel, if so, I back; it may be a rabbit, if it is, I spring." Instead of unquestioned preperception that "makes the mouth water," we have the alternative possibilities present as "free ideas," and action is in suspense, the alternative courses, that is to say, again present only in idea. It is easy to see how in such situations one free idea, a "what" sundered from its "that," will tend to loosen the sensory ties of alternative, still implicit ideas. On the cognitive side, from immediate assimilation an advance is made towards mediate cognition, towards comparison; on the active side there is advance from impulsive action towards deliberate action.[1]

We conclude, then, that implicit ideas—the products of assimilation, and integrated as such in complex percepts and the motor co-ordinations to which they lead—are more likely to emerge as free ideas the more this perceptual complexity increases. Perception in the lower animals, who give no signs of either memory or ideation, has apparently no such complexity. A fish, for example, can feel, smell, taste, see, and even hear, but we cannot assume solely on that account that it has any percepts to which its five senses contribute, as they do to our percept, say, of an orange or a peppermint. Taking voluntary movements as the index of psychical life, it would seem that the fish's movements are instigated and guided by its senses not collectively but separately. Thus a dog-fish, according to Steiner, seeks its food exclusively by scent; so that when its olfactory bulbs are severed, or the fore-brain, in which they end, is destroyed, it ceases to feed spontaneously. The carp, on the other hand, appears to search for its food wholly under the guidance of sight, and continues to do so just as well when the fore-brain is removed, the mid-brain, whence the optic nerves spring, seeming to be the chief seat of what intelligence it has.[2] Again, Bateson observes: "There can be no doubt that soles also perceive objects approaching them, for they bury themselves if a stroke at them is made with a landing-net; yet they have no recognition of a worm hanging by a thread immediately over their heads, and will not take it even if it touch them, but continue to feel for it aimlessly on the bottom of the tank, being aware of its presence by the sense of smell."[3] To this inability to combine simple percepts into one complex percept of a single object or situation we may reasonably attribute the fish's lack of true ideas, and consequent lack of sagacity. The sagacity even of the higher animals does not amount to "general intelligence," such as enables a child "to put two and two together," as we say, whatever "two and two" may stand for. So far as life consists of a series of definite situations and definite acts, so far the things done or dealt with together, the contents of the several *foci* or concentrations of attention, form so many integrated and comparatively isolated wholes. Round the more complicated of these, and closely connected with them, free ideas arise as sporadic groups, making possible those "lucid intervals," those fitful gleams of intelligence in the very heat of action, which occasionally interrupt the prevailing irrationality of the brutes. And as we cannot credit even the higher animals with general trains of ideas, just as little can we credit them with a continuous memory: indeed, it is questionable how far memory of the past, as past, belongs to them at all. For they live entirely in an up-stream, expectant attitude, and it is in this aspect that "free ideas" arise when they arise at all. We cannot imagine a dog regretting, like one of Punch's heroes, that he "did not have another slice of that mutton."[4]

The free idea (a) then at its first emergence has neither an assignable position in a memory-record, as a_1 or a_2, nor has it a definite relation as a "generic idea" to possible specializations such as a' or a''. These further developments have been dealt with in the earlier article (cf. pp. 60–63), the former as "contiguous association" determined by the successive movements of attention, the latter as so-called "association of similars," the joint result of assimilation and contiguity.

Two or three supplementary remarks seem, however, called for. First, the exclusively successional character of contiguous association has recently been denied, and its exclusively simultaneous character maintained instead. It is at once obvious that this opposition of succession and simultaneity cannot be pressed so as to exclude duration and reduce the whole process to an instantaneous event. Nor is there any ground for saying that there is a fixed and even distribution of attention to whatever is simultaneously presented: facts all point the other way. Still, though we cannot exclude the notion of process from consciousness, we may say that presentations attended to together become *pro tanto* a new whole, are synthesized or complicated. Such primary synthesis leads not to an association of ideas, but rather to the formation of one percept, which may become eventually a free idea. The disconcerted preperception which sets this free may likewise liberate a similar or contrasting idea, but it will not resolve either complex into the several "ideas" of its sensory or motor constituents, with which only the psychologist is familiar. The actual recurrence of some of these constituents may again reinstate the rest, not, however, as memories or as "thoughts," but only as tied ideas in a renewed perception.

Secondly, it has become usual to distinguish the association of contiguous experiences and the so-called association of similars or opposites as respectively external and internal *forms* of association. The new terminology is illuminating: the substitution of *forms* for *laws* marks the abandonment of the old notion that association was by "adhesion" of the contiguous and "attraction" of the similar. We are thus left to find the cause of association in interested attention; and that, we may safely say, is an adequate, and apparently the sole adequate, cause for the two commonly recognized forms of external association, the so-called simultaneous and the successive. But these two are certainly not co-ordinate; and if our analysis be sound, the former—for which we would retain the Herbartian term complication—yields us not members of an association but a member for association. So far, then, we should have but one form of association, that of the successive contents of focalized attention; and but one result, which in the earlier article was called the representation or memory continuum,[5] in contrast to the primary or presentation continuum, whence its constituents arise (cf. p. 60). Turning now to the distinction of external and internal, it at once strikes the unprejudiced mind that "internal association" is something of an anomaly, since the very notion of association implies externality. Also, on closer inspection what we find is not an association of similars or opposites as such, but—something quite distinct—a similarity or contrast of associates; of ideas, that is to say, which are contiguous members of the memory (or experience) continuum, or of ideas which have become contiguous through its reduplication.

Experimental Investigations concerning Memory and Association.

Of the vast mass of experimental work undertaken in recent years, that relating to memory and association is

[1] Some light is perhaps here thrown on the reciprocal relation of "association by contrast" and "association by similarity" as severally the differentiation of partial similars and the integration of partial dissimilars.

[5] Experience-continuum would perhaps be a better name, since it is only a preliminary to a true memory-record, as we shall presently see.

probably the most important. A brief account of some of it is therefore offered at this point, by way of illustrating the character of the "new psychology."

The learning and retaining of a stanza of poetry, say, is obviously a function of many variables, such as the mode of presentation (whether the words are heard only, or heard and seen, or both heard, seen, and spoken aloud), the length, familiarity with the words and ideas used, the number of repetitions, the attention given, &c. Familiarity of course implies previous learning and retaining; the first essential, therefore, in any attempt to study these processes from the beginning, is the exclusion of this factor. Accordingly Ebbinghaus, the pioneer in experiments of this kind,[1] devised the new material, which is now regularly employed, namely, closed monosyllables, not themselves words, and strung together promiscuously into lines of fixed length so as never to form words: *ban, rit, por, sig, nef, gud*, &c., is an instance of such "senseless verses." With very slight attention most persons would be able to reproduce three or four such syllables on a single reading or hearing; and by greater concentration six or seven might be so reproduced. This maximum, called sometimes the "span of prehension," has been repeatedly made the subject of special inquiry. In idiots it is found, as might be expected, remarkably low; in school children it increases rapidly between the ages of eight and fourteen, and then remains almost stationary, individual differences being small compared with the striking differences that appear when longer lines make repetitions necessary.[2] This comparatively constant span of prehension is doubtless closely connected with certain other psychical constants, such as the duration of the psychical present and of the primary memory-image, the *tempo* of movements of attention (p. 65), &c. There are isolated investigations of these several conditions, but the subject as a whole still awaits systematic treatment.[3] That it is not wanting in interest is evident when we consider that if our span of prehension were enlarged, a corresponding increase in the variety and range of metre and rhyme in poetry, of "phrase" in music, and of evolution in the dance would be possible. The limits at present imposed on these and like complexities find their ultimate explanation in the constants just mentioned.

With lines of greater length than seven syllables some repetition is requisite before they can be said correctly: the number of such repetitions was found by Ebbinghaus to increase very rapidly with the number of syllables to be learnt. In his own case, for lines of 12, 16, 24, 36 syllables the repetitions necessary were on the average 16·6, 30, 44, 55 respectively. Thus for a line exceeding in length that of the span of prehension only about five times, he required fifty-five times as many repetitions, if we may call the single presentation of the syllables a "repetition." Substituting poetry for gibberish of equal amount, Ebbinghaus found that one-tenth the number of repetitions sufficed; the enormous saving thus effected showing how numerous and intimate are the ready-made associations that "rhyme and reason" involve. But at one and the same time to memorize five verses even of sense requires more than five times as many repetitions as the memorizing of one. Two or three lines of inquiry here present themselves, *e.g.*, (i.) as to the comparative value of successive repetitions when several are taken together; (ii.) as to retention after an interval, as (*a*) a function of the number of repetitions previously made, and as (*b*) a function of the time; (iii.) as to the respective effects of more or less cumulating, or more or less distributing, the repetitions, on the number of these required.

(i.) It is at once obvious that beyond a certain point exhaustion of attention renders further repetition for a time futile; thus Ebbinghaus found 64 repetitions at one sitting of six 16-syllable nonsense verses, a task lasting some three-quarters of an hour, "was apt to bring on asthenia, a sort of epileptic *aura*, and the like"! But keeping well within this heroic limit, a certain "law of diminishing return," to use an economic analogy, discloses itself. Thus taking a line of 10 syllables, the number of syllables reproduced correctly and in their proper order, after 1, 3, 6, 9, and 12 "repetitions," were 2·2, 2·5, 2·8, 3·4, 3·9 respectively, as the averages of a series of experiments with each of eight persons.[4] "The first repetition is undoubtedly the best," assuming, of course, that the subjects start with their attention fully concentrated. Some persons naturally do this, many do not; the experimenter has therefore to take special precautions to secure uniformity in this respect.

(ii.) (*a*) On relearning a line after an interval of twenty-four hours there was in Ebbinghaus's case an average saving of one repetition for every three made the day before. A line of 16 syllables, for example, required some 30 repetitions, and could then be said off correctly. If only 8 repetitions were taken at first, the line being "underlearnt," it probably appeared quite strange the next day, yet the *proportional* saving was no less; on the other hand, if an additional 30 repetitions followed immediately on the first, the line being "doubly learnt," in spite of the familiarity next day apparent, the proportional saving was no greater. The *absolute* saving would, of course, be less. We are so far led to infer that the stronger associations effected by many repetitions at one time fall off more rapidly than weaker associations effected by fewer repetitions in the same way. Herbart in his "psychical dynamics"—influenced probably by physical analogies—conjectured that the "sinking" or "inhibition" of presentations generally was proportional to their intensity: the less there was to sink, the slower the sinking became. Recent experiments certainly point in this direction. (*b*) As to retention as a function of the time—we all know that memories fade with time, but not at what precise rate. Ebbinghaus, by a series of prolonged experiments, ascertained the rate to be proportional to the logarithm of the time—a result already implied in that connecting retention and intensity; albeit in inquiries of this kind independent confirmation is always of value.

(iii.) Had the proportional saving just described held good indefinitely, some 100 repetitions of the 16 syllables at one time should have dispensed with any further repetition twenty-four hours afterwards; whereas, in fact, this result seemed never attainable. Beyond a certain degree of accumulation, an ever-diminishing return was manifest, and that apparently short of the stage at which exhaustion of attention began to be felt. But, contrariwise,

[4] W. G. Smith, "The Place of Repetition in Memory," *Psychological Rev.*, 1896, pp. 20 ff. The figures given are unquestionably low, partly, as the writer points out, in consequence of the method employed, but partly, as his detailed tables show, in consequence of the lax attention of three out of his eight subjects. Objections have been taken to the plan of this investigation, but it is doubtful if they invalidate the result here mentioned. Cf. Jost, "Die Associations-festigkeit in ihrer Abhängigkeit von der Vertheilung der Wiederholungen," *Ztschr. f. Psychologie*, xiv. pp. 455 ff.

when the repetitions were distributed over several days, an ever-increasing efficiency was then the result. Thus, for Ebbinghaus, 38 repetitions spread over three days were as effective as 68 taken together. The results of careful experiments by Jost with two different subjects, using G. E. Muller's "method of telling" (to be described later on), are still more conclusive. Comparing 8 repetitions on three successive days with 4 repetitions on six, and 2 on twelve, the efficiencies, tested twenty-four hours later, were respectively as 11·5, 35, and 54; and probably, as Jost surmises, the effect of the maximum distribution—single "repetition" on twenty-four successive days—would have been more advantageous still, securing in fact the superiority of a first impression (cf. i. above) on every occasion. This result, again, is in part explained by the law of sinking already found. For if the sinking were simply proportional to the time, or were independent of the intensity, there would so far be no reason why one mode of distributing a given number of repetitions should be more economical than another. There is, however, another reason for this superiority, less clearly implied, to which we shall come presently.

Invariably, and almost of necessity, a more or less complex rhythmical articulation becomes apparent as the syllables are repeated, even when—as in the improved methods of G. E. Müller and his *collaborateurs*—they are presented singly and at regular intervals. A series of twelve syllables, for example, would be connected into six trochees, with a cæsura in the middle of the verse; while in each half of it the first and last accented syllables would be specially emphasized; thus:

bām fĭs | lūp tŏl | *gēn* kĕr || *dūb* năf | &c.

In trying to suppress this tendency and to repeat the syllables in a monotonous, *staccato* fashion, just as they were presented, the *tempo*, though really unchanged, seemed to be distinctly quickened, a consequence, doubtless, of the greater effort involved. Moreover, the attempt, which was seldom successful, about doubled the number of repetitions required for learning off, thereby showing how much is gained by this psychical organization of disconnected material. But the gain thus ensured was manifest in other ways. Each foot, whether dissyllabic or trisyllabic, became a new complex unit, the elements to be connected by successive association being thereby reduced to a half or a third, and the whole line seemingly shortened. The varied intonation, again, helped to fix the place of each foot in the verse, thus further facilitating the mind's survey of the whole. Such a transformation can hardly be accounted for so long as retention and association are regarded as merely mechanical and passive processes.

Psychical rhythm, upon which we here touch, has also been experimentally investigated at great length, alike in its physiological, psychological, and æsthetical aspects. The topic is far too intricate and unsettled for discussion here, yet two or three points may be noted in passing. We are not specially concerned with *objective* rhythms, recurring series of impressions—that is to say, in which there are actually periodic variations of intensity, interval, and the like. What is remarkable is that even a perfectly regular succession of sounds (or touches), qualitatively and quantitatively all alike, a series therefore devoid of all objective rhythm, is nevertheless apprehended as rhythmically grouped, provided the rate lies between the limits of about 0·8″ and 0·14″. The slower of these rates leads to simple groups of two, replaced by groups of four or eight as the rate increases; groups of three and six also occur, though less frequently. The average duration of the groups, whether these are large or small, is comparatively constant, measuring rather more than one second. The subject usually keeps time by taps, nods, or other accompanying movements; the pulse and respiration are also implicated. These organic rhythms have even been regarded as the prime source of all psychical rhythm and of its manifold æsthetic effects. Some connexion there is unquestionably. As the decimal system corresponds to our possession of ten fingers, and our movements to the structure of our limbs, so here we may assume that physiological processes fix the limits within which psychical rhythm is possible, but yet may be as little an adequate cause of it or its developments as fingers are of arithmetic, or legs of an Irish jig. In motor rhythms, such as the last, the initiative is obviously psychical, and the respiratory and other periodic organic processes simply follow suit. And even sensory rhythms can often be varied at the subject's own choice, or on the suggestion of another; and then again the breathing is altered in consequence. Familiar instances of such procedure are to be found in the "tunes" so readily attributed to the puff of a locomotive, to the churning of a steamer's screw, and the like. Psychical rhythm, then, we may conclude, is due to attention or apperception, but the conditions determining it are many, and their relations very complex. If the presentations to be "rhythmized" (the *rhythmizomenon*, as the Germans say) succeed each other slowly, the length (or shall we say the breadth?) of the "psychical present" tells one way: the first impression is below the threshold when the third appears. If they arrive rapidly, their intensity and duration and the span of prehension tell another way; for it is essential that they retain their individual distinctness, and only so many can be grasped at once. But if the series continue long enough or be frequently experienced, sub-groups may be treated as individuals; and indeed till some facility is acquired, the subject attending is aware of no rhythm. In the act of attention itself there are phases, in so far as expectation involves preadjustment to what is coming: usually the first members of a tact are predominant, and the rhythm tends to "fall"; several alternations of accent within a complex rhythmic whole are of course still compatible with this. But it is important to note that, whether simple or complex, the rhythm is an intuited unity as truly as a geometrical figure may be. Unlike a geometrical figure, however, it rarely or never has symmetry. We cannot reverse a tune and obtain an effect comparable with that obtained by reprinting the score backwards in line with the original. We now pass to a question in which the psychological bearing of this fact becomes apparent.[1]

But first a new method of dealing with memory-problems must be mentioned, in which the connexion between rhythmizing and memorizing has been turned to account by the Göttingen psychologists. The method of Ebbinghaus consisted in ascertaining the repetitions saved in consequence of previous repetitions, when the verse was relearnt some fixed time later. Hence this method is called the learning method or the method of saving. When, a given time after a certain number of repetitions (say) in trochaic measure, the subject is confronted with one of the accented syllables and asked to name the unaccented syllable that belongs to it, he will answer sometimes rightly, sometimes wrongly, and sometimes be unable to answer at all. This, the new, method is therefore named *Treffer-methode*, the method of "shots," or, let us say, the telling method. It enables the experimenter to obtain far more insight into details than was possible before, for the "misses" as well as the "hits" are instructive. Moreover, by measuring the time of each answer (*Trefferzeit*) and comparing these times together, much can be learnt; in stronger or recent associations, for example, the answers being quicker than in weaker or older ones.

Does association work forwards only or backwards also, as the middle link of a chain, when lifted, raises the contiguous links on either side of it? This is certainly not the case when the forward direction makes sense, but with nonsense verses, if the mechanical analogy is a sound one, such reversal is to be expected. For here there are none of the obstructing associations which "rhyme and reason" imply. In learning a verse backwards Ebbinghaus found a saving of 12·4 per cent. of the time originally taken up in learning it forwards. A saving almost as great (10·4 per cent.) was effected by relearning a like verse forwards, but skipping one syllable: the order of syllables, that is to say, being 1, 3, 5, . . . 15, 2, 4 . . . . 16. Even when learning backwards and skipping one syllable, Ebbinghaus found a saving of 5 per cent. But the number of his experiments (four) was too few to give this result much value, as he fully admits. These experiments as a whole, then, might incline us to suppose

[1] The following are among the more important papers on rhythm:—J. L. Bolton, "Rhythm," *Am. J. of Psychology*, 1894, pp. 145 ff.; E. Meumann, "Untersuchungen z. Psychologie u. Aesthetik des Rhythmus," *Phil. Studien*, x., 1894, pp. 249 ff., 393 ff.; M. K. Smith, "Rhythmus und Arbeit," *Phil. Studien*, xvi., 1900, pp. 71 ff., 197 ff.; *Arbeit und Rhythmus*, 1899, by K. Bucher, a well-known economist, bringing out the teleological aspects of rhythm.

that association does work in both directions, though the connexions backwards are considerably weaker. But if so the associations both ways should be alike at least in form —continuous, that is to say, backwards, *d c b a*, as well as forwards, *a b c d*. The facts at present available are, however, against this. In two or three hundred experiments by Müller and Pilzecker, verses of twelve syllables were repeated a set number of times in anapæstic measure —accented, that is to say, on the 3rd, 6th, 9th, and 12th. After a fixed interval the subject, confronted with one of the accented syllables, mentioned any of the other syllables which it called to mind. Now the cases in which the syllable *immediately* preceding was revived were only about half as frequent as those in which the syllable *next but one preceding* was revived; the time of telling (*Trefferzeit*) for the latter was also *shorter*. This result is incompatible with the theory of continuous backward association, but it is readily explained by the fact that the group of three syllables had become one complex whole, and it shows that the tendency to reinstate the initial member of the group is stronger than that to reinstate the middle. The saving effected in Ebbinghaus's experiment is also thus explained.[1]

A somewhat paradoxical situation is brought to light when the method of saving and the method of telling are used together. In the experiments by Jost, mentioned above, two series of verses were repeated thirty times; after an interval of twenty-four hours one series was tested by the first method and the other by the second. Two new series were then taken: the first repeated four times, and after an interval of a minute tested by the first method; the other was then repeated in like manner, and tested after the same interval by the second method. The old series was found (by the method of saving) to require on an average 5·85 repetitions for relearning, and the new 9·6; yet on the method of telling, the new series yielded 2·7 "hits," with an average time of about $1\frac{3}{4}$ second for each, while the old yielded only ·9 "hits," with an average time of $4\frac{1}{2}$ seconds for each. Thus one may be able to reproduce relatively little of a given subject-matter, and yet require only a few repetitions in order to learn it off anew; on the other hand, one may know relatively much, and still find many more repetitions requisite for such complete learning. The "age" of the associations is then important. Other things being equal, we may conclude that each fresh repetition effects more for old associations than for recent ones. It might be supposed that the strength of the old associations was more uniform and on the average greater than the strength of the new; so that while none of the old were far below the threshold, few, if any, were above it; whereas more of the new might be above the threshold though the majority had lapsed entirely. And the latter would certainly be the case if the subject of experiment tried to make sure of a few "hits," and paid no attention to the rest of the series. Due care was, however, taken that the ends of experiment should not in this way be defeated. Also, there is ample evidence to show that the supposed greater uniformity in strength of old associations is not, in fact, the rule. We seem left, then, to conjecture that the difference is the effect of the process of assimilation working subconsciously, that psychical aspect of nervous growth which Professor James has somewhere aptly characterized by saying that "we learn to skate in summer and to swim in winter." It continually happens that we can recognize connexions that we are quite unable to reproduce. To the diminished "strength" of an association, as tested by the method of telling, there may then quite well be an equivalent set-off in more developed assimilation. As a seed germinates it has less latent energy, but this is replaced by growth in root and stem: similar relations may obtain when an old association is said merely to lose "strength." On the other hand—within the range of the primary memory-image—we can often reproduce what after a longer interval we should fail to recognize. We seem warranted, then, in concluding that this conception of "association-strength," so freely used by G. E. Müller and his co-workers, requires more analysis than it has yet received. The two factors which their methods disclose in it appear to confirm the distinction we have already made between impressions and free ideas. They help us also to understand, further, the superiority of distributed over cumulated repetition, of "inwardly digesting" over "cram."

[1] There are still other forms of what seems at first sight to be regressive association, but none that do not admit of explanation without this assumption.

Objects of Higher Order: their Analysis and Genesis.

By transposing a tune from one key to another we may obtain two entirely diverse aggregates of notes, and yet the melody may remain unchanged. On the other hand, by varying the order of the notes two distinct tunes may result from the same collection of tones. Sense furnishes merely the parts: whence, then, this identity of the whole in spite of their diversity, this diversity of the whole in spite of their identity? From the sameness or difference of the several "intervals," it is replied. But the answer is insufficient; for the tune is a unity, not a mere series, and, further, with every interval the same problem recurs. For the interval, too, is a whole, though a simple one: it does not necessarily change with a change of its constituents, nor remain the same as long as their distance is unaltered. Feelings and "associations," again, cannot account for the result, inasmuch as such accompaniments are not invariably present: moreover, they obviously presuppose the melody instead of producing it. Of such complex wholes or combinations—as distinct from mere aggregates or collections—there are many forms; as, for example, geometrical figures and patterns, motions and other changes, numbers, logical connexions, &c. In view of this variety it seems to strike the unprejudiced as wild to expect that "the progress of psychophysics" may disclose an explanation of such combinations conforming to the old scholastic maxim, *Nihil est in intellectu quod non fuerit prius in sensu.* Yet hopes of such a *generatio æquivoca* are entertained![2] Meanwhile the "old psychology," at any rate, is content to regard such complex wholes as we have already done (pp. 79, 80)—as new presentations, that is to say: the products, not of a quasi-mechanical interaction of their constituents, but of intellectual synthesis.

What is here said of the combinations whereby the items of an aggregate are construed as parts of a whole holds equally of the comparisons whereby such items are related, as like or unlike, compatible or incompatible. Before either combination or comparison is possible, such items or particulars must be "given." But it is conceivable that they should be given and no intellectual synthesis ensue; such a consciousness has been happily named *anoetic*.[3] Whether or no it actually exists is another matter: it is a conceivable limit, and has the theoretical usefulness of limiting conceptions generally. But relative *anoesis* suffices here. Suppose, then, we have: (*a*) *item*, a sound; *item*, ditto; *item*, ditto; or (*b*) *item*, blue; *item*, green. The sensationalist, from Hume onwards, has complained that he does not find in the one case a

[2] Cf. *e.g.*, F. Schumann, "Zur Psychologie der Zeitanschauung," *Ztschr. f. Psychologie*, xvii. pp. 130, 136.

[3] G. F. Stout, *Analytic Psychology*, i. pp. 50 f.

further item: *total three;* nor in the other a further item: *unlikeness.* After vainly seeking the living whole among the dead particulars, he next surmises that they generate it by their conjoint action! But whence this notion of "action"; and how, if such *disjecta membra* suffice, do they so often fail of their effect, so that we cannot "see the wood for the trees"? Combinations and comparisons then, we conclude, are not given, but "grounded" on what is given, and is thus their *fundamentum.* Hence Meinong, who has studied the psychology of intellection with especial care, has called the new presentations, due to this process of "grounding" (*Fundiren*), "objects of a higher order," or ideal objects.[1] They have validity in respect of the particulars on which they are grounded, but not reality as data existing for perception alongside of such particulars.

The reader will here be reminded of Hume's distinction between knowledge and probability. His four philosophical relations, "which, depending solely upon ideas, can be the objects of knowledge and certainty—resemblance, continuity, degrees in quality, and proportions in quantity or number"—are objects of higher order, and *ideal.* "The other three, which depend not upon the idea, and may be absent or present even while *that* remains the same"—namely, identity, the situations in time and place, and causation—are thus obviously not the result of grounding or *noesis* merely, are not ideal but *empirical,* and have, that is to say, existential import. In fact, the second of these, the situations, though they imply synthesis in the wider sense in which all complex perception does, do not involve intellectual synthesis at all: are neither ideal combinations nor ideal relations. And since such temporal and spatial situations enter into both the other two—numerical identity and causation—the mixed, *à posteriori* character of these is obvious. Whatever be the defects of Hume's psychology, his classification of relations is so far sound, and its epistemological importance can hardly be overrated. It is accordingly to be regretted that the one vague term "relation" does not allow us to make these distinctions more precise. The German language, with the two terms *Verhältniss* and *Beziehung,* can do more.

When we say that two "contents" are similar, and when too they admit of analysis, we can, if need be, enumerate certain elements as the ground of their partial likeness, and certain others as maintaining their partial diversity. We may further say that, abstracting from these last, we can regard the points of resemblance as constituting a general class to which the two contents belong as specific instances. But how is either comparison or abstraction possible when the two resembling contents appear as simple, and so far unanalysable? Instances, of course, are familiar to every one: thus we call red and orange colours, and say they resemble each other more than do red and blue. In presence of this question logicians and psychologists are apt to be at loggerheads. The logician maintains that abstraction and resemblance (as distinct from qualitative identity) imply complexity; and surely here he cannot be gainsaid. Yet there are the facts: reds and blues of sorts and a whole scale of degrees of likeness and unlikeness; but no constituent parts, no assignable marks of identity or diversity, are forthcoming, such as we find when we class sugar and salt together as solid or soluble, and pronounce them like in colour and unlike in taste. Here the logician's symbols $a+b+c$, $a+b+d$, have their counterparts: there—for the percipient's consciousness at all events—they have not. We cannot "consider and attend to either the sameness or the differences in" red and blue, as we can to the like or the unlike properties in salt and sugar. None the less it would be hasty to conclude that colours or any given sensations are simple. In the first place, musical notes, which were long taken to be so, can with due practice be perceived as a complex of ground-tone and over-tones; and there is indirect evidence of still greater complexity in the case of many so-called tastes. Further, we are often struck by the likeness of complex wholes—two faces, say—long before we can discern the exact points of resemblance. Still, so long as there is no perceptible complexity in the individual presentations there can be no analysis of them and, therefore, neither abstraction nor comparison based upon it. Can we find elsewhere the complexity that generalization and comparison invariably imply? This question has been already in the main anticipated (cf. pp. 77, 80), but perhaps with undue brevity. A word or two by way of further exposition seems therefore desirable.

Though colour may be regarded as a general term applicable alike to red, green, and blue, just as animal is a general term applicable alike to bird, beast, and fish, it is a mistake to infer that the processes are the same because of this similarity in their products. We seem bound to distinguish between consciously logical or "noetic" processes and processes that are unconsciously logical or "hyponoetic," as we may perhaps call them. In the former the subjective aspect is left aside; in the latter it cannot be. The only common mark we can psychologically assign to colours is that they are all seen, and to tones—as the element of notes and noises—that they are all heard. So often as we talk of tasting tastes, smelling smells, feeling touches, language leads us to bear witness to this fact. When the sunset red changes to the twilight grey, I still see; but when the thunder follows the lightning there is a double change, though not an absolute one: from seeing I pass to hearing, but I am sentient still. And if progressive differentiation be the order of experience (cf. p. 42), then the "universal" sentience precedes the differentiations seeing, hearing, &c., and, again, the "universal" colour the differentiations, red, green, blue, &c. Such "first universals," then, are not reached by abstraction, but are given in the fundamental continuity of experience, and their subsequent differentiation admits neither of definition nor the classification applicable to discrete complexes, which are the material of logical comparison only. When red is pronounced liker or nearer to yellow than it is to green, this is because a smaller change is experienced in the transition from red to yellow than in that from red to green, and because in the latter yellow is reached and passed before green appears.[2] Proximity and resemblance are, then, so far one and the same; also both are equally relative, admit of the same indefinite gradation, and have the same limit in *zero,* regarded either as coincidence or identity. The conception of "distance between" answers, then, to what we have called a hyponoetic relation, and this is plainly distinct from the analysis of discrete complexes, with which, as said, noetic comparison is alone concerned: the one implies and the other excludes the notion of continuity and change—a fact which helps still further to distinguish the two.

Emotion and Emotional Expression.

The nature of emotion and its relation to the various organic changes and bodily movements, commonly described as its expression or manifestation, have been continually under discussion since the appearance in 1884 of the notorious article, "What is an Emotion?" in which Professor W. James[3] turned the views of Common Sense upside

[1] A. Meinong, "Ueber Gegenstände höherer Ordnung u.s.w.," *Ztschr. f. Psychologie,* xxi., 1899, pp. 182 ff. Special mention must be made of an earlier paper by C. v. Ehrenfels ("Ueber Gestaltqualitäten," *Vierteljahrsschr. f. wissensch. Philosophie,* 1890, pp. 249 ff.), round which the whole subsequent discussion of this topic centres. Cf., too, Stout, *op. cit.,* bk. i. ch. iii.

[2] Assuming, of course, that the change is the simplest or directest possible, *i.e.,* a change of "colour proper" without change of saturation.

[3] *Mind,* ix. pp. 188 ff., and, again, *Principles of Psychology,* ch. xxv. Very similar views were advanced independently, and almost at the same time, by the Danish physiologist, C. Lange: hence the name,

down. "Common Sense says: we lose our fortune, are sorry and weep; we meet a bear, are frightened and run; we are insulted by a rival, are angry and strike." But, Professor James continues, "the hypothesis here to be defended says that this order of sequence is incorrect: that the one mental state is not immediately induced by the other, that the bodily manifestations must first be interposed between, and that the more rational statement is that we feel sorry because we cry, angry because we strike, afraid because we tremble, and not that we cry, strike, or tremble because we are sorry, angry, or fearful, as the case may be." In a word, whereas it is commonly supposed that the emotion precedes and produces the expression, it seems here to be maintained that the expression precedes and produces the emotion. But the sequence denied in the first case is a psychological sequence, the sequence maintained in the second is a physiological sequence. The subject's experiences of the bodily expressions is here the emotion, and these are physically, not psychically, determined. "They are sensational processes," says Professor James; "processes due to inward currents set up by physical happenings."

The new theory is, then, in part psychological, in part psychophysical. As to the first part, which the author calls "the vital point of the whole theory," it consists mainly in exposing the ambiguity of the phrase "bodily expression of an emotion"—a phrase which is liable to mislead us into fancying that emotion, like thought, may be antecedent to, or independent of, any expression or utterance. My fear or anger may chance to be *expressive* to another, but they are of necessity *impressive* to me. "A disembodied human emotion is a sheer nonentity." In so far as I have a certain emotion, in so far I have "the feelings of its bodily symptoms." This is true, not to say trite; but how do these symptoms arise? With this question we pass to the psychophysical side of the theory, and here it becomes perplexing, and is itself perplexed; for to this question it is driven to return two distinct and divergent answers. First, we are told that it is not the emotion that gives rise to the bodily expression, but that, on the contrary, "the bodily changes follow directly the perception of the existing fact," it being beyond doubt "that objects do excite bodily changes by a preorganized mechanism." Again: "Each emotion is," for Professor James, "a resultant of a sum of elements, and each element is caused by a physiological process of a sort already well known. The elements are all organic changes, and each of them is *the reflex effect of the existing object*." The old attempts at classification and description being contemptuously dismissed as belonging only to "the lowest stage of science," we are informed that now we step from a superficial to a deep order of inquiry. "The questions now are *causal*: 'Just what changes does this object and what changes does that object excite?' and 'How come they to excite these particular changes, and not others?'" But we have not had to wait for the James-Lange theory to raise these questions, and surely there are none that bring out its defects more glaringly. "Objects" that determine bodily changes by means of preorganized mechanism and without psychical interposition might fairly be taken to be physical objects; and indeed the whole process is expressly described as reflex. But only very slovenly physiologists talk of "objects" exciting reflexes: it is inexact even to say that sensations do so. All that reflex action requires is a *stimulus*. "The essence of a reflex action," says Foster, "consists in the transmutation, by means of the irritable protoplasm of a nerve-cell, of afferent into efferent impulses." Let Professor James be confronted first by a chained bear and next by a bear at large: to the one object he presents a bun, and to the other a clean pair of heels; or let him first be thrilled by a Beethoven symphony and then by a Raphael Madonna. Will he now undertake to account, in terms of stimuli and their reflex effects, for the very different results of the similar "causes" in the one case, or for the similar results of the very different "causes" in the other? Such a challenge would certainly be declined, and Professor James would remind us that in his nomenclature "it is the total situation on which the reaction of the subject is made."[1] But there is just a world of difference between "object" = stimulus transformed by preorganized mechanism into an efferent discharge, and "object" = total situation to which the subject reacts. The attempt to explain emotion causally on the lines of the former meaning lands us in the conscious automaton theory, with which we must deal presently: this Professor James rejects. The latter meaning, on the other hand, involves the recognition of the subject's attitude as essential to the reaction, and of this as determined by pleasure, pain, or by some "interest" resting ultimately on these. Such, with scarcely an exception, has always been, and still remains, the analysis of emotion in vogue among psychologists. It brings to the fore a new category, that of worth or value, one wholly extraneous to the physiologist's domain, and repugnant to the mechanical analogies which are there in place. No doubt such a conception is attained only by reflection, but the experiences from which it is drawn, the affective states, the conative tendencies of the subject experiencing, must first precede. From this central standpoint alone the objective situation has a worth which explains the subject's attitude, and here alone can we find the clue which will enable us to answer the questions of cause that Professor James propounds.

The experimental investigations of Mosso, Féré, Lehmann, and others have shown that the vasomotor and such like bodily changes as are prominent in emotional excitement are present also to some extent in all forms of conscious activity. The more unwonted and interesting the situation, the more diffused movements predominate over movements that are purposive; the further assimilation, both on the cognitive and the reactive side, has advanced, the more diffusion is replaced by restriction and adaptation. But we are not warranted in separating these factors of voluntary activity into distinct processes, as the physiologist, for example, separates the functions of striped and unstriped muscle. Unless we are prepared to treat *all* activity as reflex—as the physiologist may quite well do, if he keep strictly to his own point of view—it does not seem possible to regard emotional expression as so much organic sensation with which purposive movement has nothing to do. No doubt this connexion of vegetal and animal functions remains one of the obscurest in all psycho-biology, though its teleological fitness is obvious enough.

Nevertheless, Professor James's main position is that an emotion is but a sum of organic sensations; and in order to establish this he is led to the second and very different statement which we have now to examine. Here, so far from suggesting inquiries as to the "objects" that excite emotion, his point is to maintain that in so far as the bodily cause is set up, *be the means what they may*, in so far the emotion is present.[2] And here, at length, the contention is explicit: Emotions *are* a certain complex of organic sensations, and such complexes *are* emotions: the two are not merely coexistent, they are identical. The exciting object is thus, after all, physiological; that is to say, it is whatever stimulus sets up the sensations. It cannot be psychological, "the total situation for the

James-Lange theory, by which their views are now commonly known. Of Lange's work, a German translation, *Ueber Gemüthsbewegungen: eine psychophysiologische Studie*, was published in 1887.

[1] "Physical Basis of Emotion," *Psychological Review*, 1894, p. 518. In this reply to criticisms Professor James is supposed to have modified his views: it would be nearer the truth to say that he has made admissions incompatible with them.

[2] *Text-Book of Psychology*, 1890, p. 383.

reacting subject," for in this sense the emotion, it is maintained, may be "objectless." In support of his position Professor James first of all cites pathological cases of such objectless emotion. He next follows up these with accounts of other cases in which emotional apathy seemed to keep pace with sensory anæsthesia, arguing that, according to his theory, a subject absolutely anæsthetic should also be incapable of emotion, although "emotion-inspiring objects might evoke the usual bodily expression from him." Whether *any* testimony from lunatics, hypnotics, and other minds diseased could suffice to establish this novel doctrine is questionable: that the evidence so far adduced is insufficient, Professor James seems himself to allow. There are some four or five of the apathetic cases altogether: three of them are regarded by the mental pathologists who describe them as adverse to Professor James's theory.[1] Of the fourth case, reported by a pathologist on Professor James's side, the latter himself candidly observes, "We must remember that the patient's inemotivity may have been a co-ordinate result with the anæsthesia of his neural lesions, and not the anæsthesia's mere effect." This missing link in the argument is supplied by the experiments of Professor Sherrington,[2] and these show conclusively that normal emotional states *are* possible along with complete visceral anæsthesia. As to emotional excitement induced by intoxication or disease, and so far *groundless*, the most that can safely be said is that the object may be vague, ill-defined, and shifting, but not that it is absent altogether. States of physical exaltation, depression, or irritability readily arouse by association appropriate *troupes* of imagery; only when they fail of this are we entitled to say that there is no object, and then we must add that there is also no emotion.

Relation of Body and Mind: Psychophysical Parallelism.

Of disembodied mind as a *res completa* we can form no conception. It might even be said that such a conception is a contradiction in terms, since living experience refuses to be sundered into the unmediated dualism of *res cogitans* and *res extensa*, as in Descartes' Philosophy; and since, again, the subject of experience is invariably related to the objective environment by means of its organism. It is this connexion of mind and organism that we have now to consider. In development and efficiency, in the intensity and complexity of their processes, mind and brain keep invariably and exactly in line together. Striking and impressive instances of this correspondence are to be found in comparative psychology, and especially in mental pathology; but it is needless here to enlarge on a point which in the main is beyond dispute. In this correspondence lay the plausibility of the old materialism. But a closer scrutiny discloses an impressive disparity—that of quality may suffice as an example. We reject materialism, accordingly, while still maintaining this *Psychoneural Parallelism* to be a well-established fact. From this we must distinguish a second sense of parallelism founded on the disparity just mentioned as also pertaining to the psychical and neural correlates. We may call this *Physiologico-psychological*, or, more briefly, *Methodological, Parallelism.* It rejects, as illogical, the attempt to penetrate to psychical facts from the standpoint of physiology, so persistently and confidently pursued by the old materialists. It also forbids the psychologist to piece out his own shortcomings with tags borrowed from the physiologist. The conceptions of the two sciences are to be kept distinct, as the facts themselves to which they relate are distinct (cf. above, p. 57). Confusion is inevitable if the psychologist, for example, talks of his volition as the cause of his arm moving, when by arm movement he means the process described by the physiologist in terms of efferent excitations, muscular flexions, and so forth; or if the physiologist speaks of a sensation of red as produced by retinal stimulation due to light-waves of a certain length, when by sensation he means what he immediately experiences on looking at a field-poppy. This methodological convention, as we may call it, implies a more stringent interpretation of causation than that expounded by J. S. Mill and his contemporaries. It does not, however, forbid psychological inferences on the basis of physiological facts, nor *vice versâ*. But in spite of this distinctness of the facts, and of the standpoints from which they are respectively studied, their causal relation cannot be simply ignored: it is, however, a problem that pertains strictly to the higher standpoint of philosophy. There have been in all four different theories of this relation within modern times: (1) that of mutual interaction—the Common-sense view—very inconsistently maintained by Descartes; (2) the "Occasionalism" substituted for this by Geulincx and the later Cartesians; (3) the Pre-established Harmony of Leibnitz; and (4) the Monism of Spinoza, which reduced matter and mind to parallel attributes of the One Substance.[3] The last of these—severed, however, from Spinoza's metaphysics—is now the prevailing theory, and to it the term *Psychophysical Parallelism* most properly applies. For whereas the parallelism first mentioned states a real correspondence between psychical processes and neural processes, but leaves open the question of a possible interaction between matter and mind, psychophysical parallelism is a pure hypothesis concerning the relation of psychical facts to physical theories, on the ground of which—as we shall presently see—any interaction between matter and mind is expressly denied.

But in the exposition of this hypothesis these two meanings of parallelism are frequently confused or interchanged. The same term "body" is applied both to an aggregate of matter and to the living organism. Now life must be regarded as either inherent in matter, or as the result simply of a particular material configuration, or as physically inexplicable. But, for the present at all events, it cannot be explained physically; nor are we even within measurable distance of such an explanation: so much is beyond cavil. Yet the hypothesis of psychophysical parallelism confines us to one or other of the former alternatives: at the same time its unwarrantable identification with psychoneural parallelism—where we find a real correspondence between mind and *organism*—tends to conceal the gravity of such assumptions. The standpoint of physiology, therefore, must be described not as identical with that of physics, but as intermediate between it and the standpoint of psychology. If the fact of life could be reduced to physical terms, physiology then, no doubt, would have to fall into line with physics, much as chemistry, for example, may have had to do. On the other hand, till a physical explanation of life is forthcoming, physiology belongs, with psychology, to the biological group of sciences, and cannot divest itself completely of the teleological conceptions essential to them, not a vestige of which belongs to bare physics. It is just because of this community in their conceptions that there actually is a certain "point to point" correspondence or parallelism between the psychical and the neural: as an *organ* a neuron is a unit; physically regarded, it ceases to be one. Yet this illicit identification of organism and material body is thought to be legitimate, inasmuch as physiological processes are found to rest invariably on a physical basis; and inasmuch as, though methodological parallelism forbids the physiologist to identify *psychosis* with *neurosis*, no limits can be imposed on his efforts to ascertain the mechanism of the neurosis itself. But if this be granted, is not psychophysical parallelism justified, in principle at all events? By no means: as little, for example, as an

[1] G. H. J. Berkley, "Two Cases of General Cutaneous and Sensory Anæsthesia without Marked Psychical Implications," *Brain*, 1891, vol. xiv. pp. 441 ff.

[2] "Experiments on the Value of Vascular and Visceral Factors for the Genesis of Emotion," *Proc. Roy. Soc.*, 1900, lxvi. pp. 390 ff.: and *Nature*, vol. lxii. pp. 328 ff.

[3] Particulars of these theories will be found in the articles dealing with the authors of them.

explanation of the mechanism of a locomotive would justify us in ascribing its origin, its maintenance, or its guidance to the machine itself. When life and mind are explained by their mechanism, the physicist may summon the biologist, as Mephistopheles did Faust, "*Her zu mir*": then, but not before.

A favourite mode of stating psychophysical parallelism is that known as the *Double Aspect Theory*. In this, besides the unjustified identification of the first and third meanings, we find also an equally unjustified interpretation of parallelism in the second sense. All that methodology prescribes is that psychologists and neurologists—and, we may add, that physicists too—shall severally, as "specialists," mind their own business. Again, all that the first two jointly ascertain is simply the fact of correspondence: the explanation of it is still to seek. Two propositions are now advanced which are held to meet this need. First—and negatively—the connexion, it is said, is not causal: mind does not act on body, nor body on mind: the changes on each side form two independent series, each "going along by itself." In other words, the series themselves are said to exemplify what methodology enjoins on the sciences that investigate them—they mind their own business and never intrude into each other's domains. Nevertheless their interaction is not *primâ facie* contradictory or absurd, and ordinary thought, as we have seen, assumes that it exists. What evidence, then, is there for denying it absolutely? Empirical evidence for such a universal negative there can hardly be; it must be established therefore—if established at all—on *à priori* grounds. Meanwhile two facts already noticed make seriously against it. On the psychical side sensations point to an intrusion of some sort, and are not psychically explicable (cf. above, p. 57); and the like—for the present at all events—must be said of the fact of life on the physical side. Apart from all this, it seems plain that methodological parallelism, so far from justifying the denial of interaction, simply precludes its discussion on the dualistic level to which that parallelism is confined. The gulf implied is indeed not absolute—of so much, parallelism in the first sense assures us—but those who are forced to keep to their own side of it obviously are not the people to settle how it is crossed. We are aware that the dualism is not absolute, it is replied: it is only phenomenal, and the two series of phenomena are conditioned by an underlying unity of substance. Such is the second, and positive, proposition of the Double Aspect Theory. Again asking for evidence, we learn that this underlying unity is unknown—in fact, unknowable. This unknowable substance is assumed, then, simply because—*the impossibility of causal connexion being taken as established*—no other alternative remains. The negative proposition is thus the foundation of the theory, and without it this agnostic monism becomes entirely arbitrary. We have therefore to continue our search for the grounds on which the possibility of interaction is denied. But it will be worth while first to examine certain ambiguities besetting the positive statement of the Double Aspect Theory.

Difference of aspect may result solely from difference of standpoint, or it may be due to difference in the reality itself. The circle, seen as concave from within and as convex from without, is an ancient instance of the first still in great favour; the pillar, that was cloud and darkness to the Egyptians but light to the children of Israel, may serve to exemplify the second. The former we may call the phenomenal, and the latter the ontal, meaning of "aspect." With these two very different meanings our theory plays fast and loose as suits its own convenience. To do this is easy—in so far as the reality is unknown and unknowable; and necessary—since in the end, the reality, however unknowable, must somehow include both the phenomenal aspects and all that pertains to them, and so far therefore be known. In dealing with "aspect" in the first sense, the one question to be raised concerns the nature and relation of the respective standpoints. To the one belongs what we know as individual experience, and this is essentially concrete, immediate, and qualitatively diverse; to the other belongs an abstract, conceptual scheme, wholly quantitative, familiarly known as the mechanical theory. Between these there is plainly no such co-ordination as the inept comparison with the inside and the outside of a circle implies.[1] Neither is there, on the other hand, the same complete opposition; for the entire mechanical theory is based upon individual experience as enlarged and developed by intersubjective intercourse (cf. above, p. 56). Both the sense-knowledge of the one and the thought-knowledge of the other relate to the one objective factor involved in both. So far, then, there is fundamentally only one standpoint—that of the subjective factor to the objective factor, which is immediately perceived in the one and mediately conceived in the other. The question here raised is then primarily epistemological, but it is a question, as we have seen, in which psychology is intimately concerned. "Aspect" in the second sense is independent of standpoints. We have here to deal with attributes of the one reality, more or less in Spinoza's sense; this reality itself is so far dual. But in this case the question of causal connexion between these attributes is not escaped. For to know that a thing has invariably two attributes does not enable us to determine straightway how the changes or "modes" of the one are connected with those of the other. (1) The same attribute might be always the initiating or independent variant, and then would come the question of finding out which of the two it was; or (2) it might be that now one, now the other, took the lead, the grounds of this alternation being then the matter for inquiry; or, finally, (3) it might be, as our theory assumes, that there was but a single series of double changes. The questions here raised are philosophical questions, but again they are questions in which psychology is intimately concerned. Our examination thus yields two results: first, there is fundamentally only a single standpoint—that of experience, now at the perceptual, now at the conceptual, level; and, secondly, the distinction of aspects is not merely phenomenal, but pertains "somehow" to reality. The question is how; and this leads us to resume our inquiry into the grounds on which interaction is denied.

They are neither psychological nor physiological, but—in spite of the outstanding difficulties connected with sensation and life which these sciences severally raise—such denial is upheld mainly on the strength of an interpretation of the principle known as the conservation of energy—an interpretation of it, however, which many of the ablest physicists disallow. The energy of the physical world, it is maintained, is a strictly invariable amount; matter, therefore, cannot act on mind, for such action would entail a decrease, nor can mind act on matter, since that would entail an increase, of this energy. In other words, the material world is held to be a "closed system"; and as all the changes within it are mass-motions, there can be none which are not the effect and equivalent of antecedent mass-motions. But now this statement must be established

[1] In fact, if there were, since it is only as we contemplate finite portions of the circle that the distinction of concave and convex is present, the nearer we approximated to its elements the more this difference of aspect would disappear. If on the physical side we called these elements atoms, there would be an answering element of "mind-stuff" on the psychical; and there would be no more unity and no other diversity in a given man's mind than in his brain regarded as a complex of atoms. Wild as all this seems, yet views of the kind have been seriously put forward more than once as the logical outcome of psychophysical parallelism.

on physical grounds: to assume it otherwise would be openly to beg the very question at issue. For if mind does act on matter, the physical mechanism *is* subject to changes from without, and so often its motions are *not* due to antecedent motions; and this—the Common-sense view—cannot, of course, be summarily dismissed as impossible or absurd. Now energy is essentially a metrical notion, and its conservation in finite and isolated material systems has been ascertained by careful quantitative experiments. To say that the energy of the material universe is constant is only a way of expressing the generalization of this result—is tantamount, in other words, to saying that it holds of all finite isolated systems. The *whole* universe may perhaps be called isolated, but we do not know that it is finite. We cannot, therefore, apply metrical conceptions to it, and consequently cannot interpret the conservation of energy as meaning that the physical part of it is a closed system. But if not a closed system, then the energy of a given group of bodies may be increased or decreased without interaction between that group and other bodies—may be increased or decreased by psychophysical interaction, that is to say. And, moreover, such psychophysical interaction would not invalidate the conservation of energy, rightly understood; for that merely means that the energy of a group of bodies can be altered only from without, and this might happen whenever such interaction occurred.[1] We seem, therefore, justified for the present in rejecting psychophysical parallelism as one of the three possible modes of relating mind and matter regarded as attributes of the real. Not only are there psychological as well as biological objections which it has not yet overcome, but there are so far no physical grounds in its favour.

At this point we may again for a moment turn aside to consider a modified form of the doctrine—the so-called *Conscious Automaton Theory*, an attempt to blend the old Cartesian views concerning the minds of man and brute. According to Professor Huxley, the best known modern exponent of this theory, "our mental conditions are simply the symbols in consciousness of the changes that take place automatically in the organism." This consciousness is supposed "to be related to the mechanism of the body simply as a collateral product of its working, and to be as completely without any power of modifying that working as the steam-whistle . . . is without influence upon the locomotive's machinery": thus "the feeling we call volition is not the cause of a voluntary act, but the symbol of that state of the brain which is the immediate cause of that act." In other words, physical changes are held to be independent of psychical, whereas psychical changes are declared to be their "collateral products." They are called *collateral* products, or "epiphenomena" to obviate the charge of materialism, and to conform to the interpretation of the conservation of energy that we have just discussed. Such a theory is, strictly speaking, one of parallelism no longer: rather it adopts, instead, the first of the two possibilities we have noted above as opposed to parallelism. According to it, matter is the initiating or independent variant, on whose changes mind simply follows suit. It is open to two fatal objections. First, it is methodologically unsound: its psychology is physiological in the bad sense. It regards all states of consciousness as passive, *i.e.*, as ultimately either "feelings" or "reflexes." Volitional activity is declared illusory; and if this be true, intellectual activity must be illusory too. But to detect illusion requires experience of reality—we only know the sham by knowing the genuine first; and even passive states could not be experienced as such save by contrast with states that are active. To the physical side, then, we naturally turn for this knowledge which we are told is not to be found on the psychical; and we do so the more readily as, according to the present theory, the physical holds the primary place. But we turn in vain; for matter is inert, and its energy only "works" by taking the line of least resistance, like water running down hill. Moreover, such activity as we are in search of could only be found here in case the physical mechanism showed signs of being intelligently directed, and that would also be evidence that psychical activity is not illusory. Is, then, the physical side after all primary? No, we reply: the assumption is epistemologically unsound. This is our second objection. The *order* implied in the distinction of physical phenomena and psychical *epi*phenomena is contrary to all experience and indefensible. A physical phenomenon is either actually perceived or possibly perceptible; otherwise it is devoid of empirical reality altogether. But objects of perception are so far psychical; that is, they belong to immediate or individual experience. Therefore we cannot regard them as independent of this experience, nor this as their collateral product, *i.e.*, as epiphenomenal. Again, the *phenomenality* supposed to be common to both involves, as we have already seen, a fundamental identity in the standpoint of each: they belong to the same continuous experience at different levels. And lastly, their abstract, merely quantitative, character shows that it is the conceptions of physics, and not the fact of immediate experience, that are symbolic, and so to say epithetic. The attempt—either empirically or speculatively—to outflank mind by way of matter is an absurdity on a par with getting into a basket in the hope of being able to carry oneself.

These epistemological considerations may help us to deal with the prime and ultimate argument for strict parallelism. When all is said and done, it is urged, still the interaction of mind and matter remains inconceivable:

Tangere enim et tangi nisi corpus nulla potest res.

But this is hardly a sufficient reason for denying what is *primâ facie* a fact. Occasionalists, from Geulincx to Lotze, have acknowledged the same obscurity in *all* cases of transitive action. Yet they did not venture to deny that sensations were interruptions in the psychical series, the "occasions" for which were only to be found in the physical; nor that purposive movements were interruptions in the physical series, the "occasions" for which were only to be found in the psychical. And surely such a position is more in harmony with experience than that of the parallelists, who maintain that each series "goes along of itself"—a statement which, as we have repeatedly urged, contradicts psychology and assumes the physical "explanation" of life. Whereas occasionalism leaves the question of ultimate means to be dealt with by metaphysics,[2] parallelism forecloses it on the basis of a ready-made metaphysics—modern naturalism, that is to say—in which psychology as an independent science is entirely ignored. Starting with a dualism as absolute as that of Descartes — but replacing his two substances by one, enjoying the *otium cum dignitate* of the Unknowable—starting, too, from the physical side, no wonder such a philosophy finds that what is for us the most familiar and of the supremest interest, the concrete world of sense and striving, is for it the altogether inconceivable, the supreme "world riddle." And yet if the naturalist could deign to listen to the plainest teachings of psychology and of epistemology, the riddle would seem no longer insoluble, for

[1] The possibility is enough: we cannot tell what actually happens, and do not, therefore, know how far the direction of matter by mind calls for a modification or limitation of physical hypotheses. Cf. Ward, *Naturalism and Agnosticism*, 1899, vol. ii. pp. 73–86.

[2] Cf. Lotze, *Metaphysik*, sec. 61 *fin.*

his phenomenal dualism and his agnostic monism would alike disappear. The material mechanism which he calls Nature would rank not as the profoundest reality there is to know: it would rather become—what indeed "machine" primarily connotes—an instrumentality subservient to the "occasions" of the living world of ends; and so regarded, it would cease to be merely calculable, and would be found intelligible as well. Psychophysical parallelism, then, we conclude, is not a philosophically tenable position; and—pending the metaphysical discussion as to the ultimate nature of interaction generally—we have to rest content with the second of the three possible modes of connexion above defined, as occasionalism formulates it. According to this, the two series, the psychical and the physical, are not independent and "closed" against each other; but in certain circumstances—*e.g.*, in perception—physical changes are the occasion of psychical, and in certain circumstances—*e.g.*, in purposive movements—psychical changes are the occasion of physical: the one change not being explicable from its psychical antecedents, nor the other from its physical.

Into the metaphysical discussion we cannot, of course, enter here. It must suffice to say that it will not be conducted on the lines of our present inquiry: it will not start from a dualism of matter and mind, either regarded as substances or as phenomena. Its problem will rather be the interaction of subject and object—a duality in the unity of experience, which by no means coincides with the dualism of matter and mind, neurosis and psychosis, and the like.

Comparative Psychology.

Psychoneural parallelism is no doubt a well-established generalization; nevertheless, concerning its exact range and its precise meaning there are differences of opinion. It is applicable, every one will allow, so soon as there is evidence of experiences individually acquired (cf. p. 55 above); and from such point onwards, in ascending any biological phylum, we find that the psychical and neural aspects differentiate and develop together. But how when we descend? Interpreting the neural correlate physiologically, and not morphologically, as referring primarily to function and not to structure, we find it still present as irritability and conductivity (leading to contraction, secretion, &c.), even in unicellular organisms. But as at higher levels psychosis is correlative to neurosis, the principle of continuity would justify us in assuming a like correspondence here. Moreover, "learning by experience," the comparative psychologist's criterion, obviously presupposes some antecedent and underlying process, of which it is the differentiation and development. And our general analysis of mind, if correct, enables us to describe this process—"the irreducible psychical minimum," of which we are here in search. We have such complete psychosis—and it is the simplest we know—in the emotional or diffused movements that follow immediately upon sensation; and these are so far purposive—though not intentional—that they tend to heighten or retain what is pleasurable, and to alleviate or remove what is painful (cf. pp. 43 and 73). Given that plasticity,[1] which is the psychological presupposition of all acquisition, then learning by experience is a possible development from such a primitive stage.

But though every psychosis have its concomitant neurosis, it is uncertain how far the converse holds good. The action of the heart, for example, depends upon neuroses of which we have now no *direct* consciousness. Facts of this kind have led to three hypotheses concerning the lowest forms of life, differing more or less from that just proposed. (i.) Perfectibility and instinct are found, it is said, to be in inverse ratio. Hence in the lowest forms of life there is no "learning by experience," because a stationary state of complete adjustment to environment has been already attained, and all reactions have therefore become "secondarily automatic": consciousness having served its purpose, has disappeared. To such a very Buddhistic psychology it may be objected: (1) that even organic reflexes tell upon the so-called vital sense or *cœnæsthesis*, and so far—the irreducible minimum being still intact—do not preclude all possibility of learning, should occasion arise; and (2) that the psychical life even of a Protozoan does not, according to the best evidence, show any such mechanical finality as is here supposed. (ii.) According to the second view, which is advocated by Mr Herbert Spencer, the behaviour of the lower organisms is wholly made up of such reflexes, supposed to be devoid of all psychical concomitants; but consciousness—so far from having disappeared—first comes upon the scene at the opportune moment when the increasing complexity of the mechanism calls for its guidance. Psychologically this hypothesis is less defensible than the last, and it has already been dealt with at some length (cf. pp. 42 *fin.*, 43). It not only assumes, as that does, far more uniformity in the interaction of organism and environment than the facts warrant, but in regarding life as prior to mind, and as the means of its evolution, it burdens science with two insoluble problems instead of one. For even if it were possible chemically to build up protoplasm, we should still be as far from organisms as a heap of bricks are from putting themselves together as a house. (iii.) The last view we have to notice is essentially an extension of the preceding, and is chiefly interesting as a *reductio ad absurdum* of that. The physics of colloidal substances—at present wanting, but confidently expected "in the near future" by certain biologists—is the key which is to unlock the mysteries of protoplasm. Certain organisms, regarded as varieties of this substance, react positively to a given physical property of the environment, and others negatively: thus a moth flies towards the light, and a centipede runs from it—the one is positively, the other negatively, "heliotropic"; the radicle of a seed, growing downwards, is positively, the plumule, growing upwards, is negatively, "geotropic." Instincts are but complexes of such tropisms, and owe their character entirely to the symmetrical form and definite structure of the colloidal substance. Now if it facilitate the work of the biologist to say that when what we ordinarily regard as a hungry caterpillar climbs to the tip of a branch, it is forced so to do by positive heliotropism; that then positive chemiotropism sets up mastication of the young buds; and that, lastly, "we can imagine this process leading to the destruction of the substances in the skin of the animal that are sensitive to light, and upon which the heliotropism depended," so leaving it free to crawl downwards and come in contact with the new buds which have in the meantime unfolded[2]—if such language serve any useful purpose, all well and good; only it must be applied to the hungry man too: in short, all behaviour must be described in the same terms. For the champion of colloids to betake himself to consciousness as he approaches the higher forms of life, is as much a breach of methodological parallelism as it is for the psychologist to fall back upon protoplasm as he approaches the lower. But to suppose that psychical processes first appear in the complicated form of association of ideas—which learning by experience is taken to imply—and at the same time to assume that

[1] Plasticity—the psychological "*à priori*" or ground of the possibility of experience—is a convenient term to express what is implied in retentiveness and differentiation.

[2] Cf. Loeb, *Comparative Psychology*, 1901, pp. 188 ff.—an interesting book, full of psychological crudities.

such experience, even when it appears, is "ultimately due to the motions of colloidal substances," these are incongruous absurdities which only the grossest ignorance would be bold enough to maintain.

Concluding, as we have done, that mind and matter—as we may provisionally call them—do really interact, we naturally infer that organic structures are not the result solely of material processes, but involve the co-operation of mental direction and selection: in other words, we are led to regard structure as partly shaped and perfected by function, rather than function as solely determined by structure, itself mechanically evolved. And such a view is justified by the fact that mechanical evolution is primarily a process of "degradation" rather than development, a case of *facilis descensus* contrasting with the upward struggle of life *per aspera ad astra*. Still, the notion of life or mind as formative and directive has its difficulties. In the first place, we have no experience of mind organizing matter—no experience of the actual process, that is to say—however sure we may feel of the fact. Hence the occasionalism to which here, at any rate, science is confined. But even so, the difficulty is not wholly removed. In the handicrafts whence we derive the conception of organs the artificer handles, but does not literally order, his tools—as if they too were intelligent. The conscious direction of such movements is doubtless facilitated by the fact that many of the complex co-ordinations actually involved in them are carried out automatically, thanks to structural modifications, either inherited or acquired. And, regarding life phylogenetically, we can imagine this process carried back indefinitely. Indeed, if it be illogical to talk of mechanisms evolving themselves and giving rise to the beings whose ends they serve, we have no choice but to accept this dualism of mind-shaping and matter inert. No choice, that is, unless we can establish the primacy of the psychological standpoint. Here we have duality but not dualism, and the object is not inert. But still there remain two difficulties,—possibly resolvable into one,—the plasticity already referred to as involved in all biological development and hereditary transmission; as to these, psychology is almost wholly in the dark.[1]

AUTHORITIES.—**Historical.**—The history of psychology is still strangely neglected. Max Dessoir has commenced a *Geschichte der neueren deutschen Psychologie*, comprising three volumes: one section of the first, dealing with the 17th century writers prior to Kant, has appeared (2nd ed., 1897); it contains a useful collection of material. From *Les origines de la Psychologie contemporaine* (1897), by the neo-Thomist scholar, Msgr. D. Mercier, much may be learnt, though its purpose is not primarily historical.

Positive.—The output of systematic works on psychology within the last twenty-five years is quite unprecedented. One of the most important of these—for the English reader the most important—is the *Principles of Psychology*, 2 vols., 1890, by W. James. Other works in English calling for special mention are G. F. Stout, *Analytic Psychology*, 2 vols., 1896; *A Manual of Psychology*, 2nd ed., 1901; Höffding, *Outlines of Psychology*, 1891 (translated from Danish); G. T. Ladd, *Psychology, Descriptive and Explanatory*, 1894; W. Wundt, *Gründriss der Psychologie*, 4th ed., 1901 (translated). Dealing mainly with experimental psychology are Külpe, *Gründriss der Psychologie auf experimenteller Grundlage dargestellt*, 1893 (translated); Ebbinghaus, *Grundzüge der Psychologie*, 1902, still in course of publication; and E. B. Titchener, *Experimental Psychology: a Manual of Laboratory Practice*, 2 vols., 1901.

Specially interesting as treating psychological problems on new lines are *La Psychologie des Idées-forces*, by A. Fouillée, 2 vols., 1893—perhaps the best French contribution to recent psychology; its cardinal point is the fundamentally dynamical character of the psychical. R. Avenarius, *Kritik der reinen Erfahrung*, 2 vols., 1888–90, an attempt, on the model of Kirchhoff and Mach's treatment of physics, to *describe* experience, taking the relation of the central nervous system to the environment as starting-point. Its strange and forbidding terminology prevented the timely recognition of its merits; but since the author's death in 1896—from overwork and disappointment—quite a literature has grown up, partly expository, partly controversial, devoted to this latest *critique*. H. Cornelius, *Psychologie als Erfahrungswissenschaft*, 1897, rather epistemological than psychological, and claiming affinity with the *critiques* of Kant and Avenarius. In J. Rehmke's *Lehrbuch der allgemeinen Psychologie*, 1894—a psychology *with* a soul, and claiming to be philosophy as well—the problems of perception and of psycho-neural interaction are discussed at length. F. Brentano, *Psychologie vom empirischen Standpunkte*, Bd. i., 1874, and still unfortunately incomplete: Brentano treats presentations and judgments as fundamentally distinct, feeling and willing, on the other hand, as fundamentally one. His influence on Austrian psychologists has been considerable, and is more or less apparent in the following:—K. Twardowski, *Zur Lehre vom Inhalt und Gegenstand der Vorstellungen*, 1894; A. Meinong, *Psychologisch-ethische Untersuchungen zur Werththeorie*, 1894; v. Ehrenfels, *System der Werththeorie*, 2 vols., 1897–98; A. Höfler, *Psychologie*, 1897.

Important as treating of particular topics are C. Stumpf, *Tonpsychologie*, 2 vols, 1883–90; A. Lehmann, *Die Hauptgesetze des menschlichen Gefühlsleben* (translated from the Danish), 1892; various monographs by T. Ribot on diseases of memory, will, personality, on the psychology of attention, of the emotions, of general ideas, &c.—all translated into English; J. M. Baldwin, *Social and Ethical Interpretations in Mental Development*, 1897; W. Wundt, *Volkerpsychologie*, 1900, 3 vols., in course of publication.

Later editions have appeared of many of the works mentioned in the earlier article, Sully's *Outlines* being replaced by a much fuller work, *The Human Mind*, 2 vols., 1892.

There are now several periodicals devoted exclusively to psychology, the chief being the *American Journal of Psychology*; the *Psychological Review*; *Zeitschrift für Psychologie und Physiologie der Sinnesorgane*; and *L'Année Psychologique*.

(J. W*.)

[1] On the subject of comparative psychology generally, see *Animal Behaviour*, 1900, by Prof. C. Lloyd Morgan; L. T. Hobhouse, *Mind in Evolution*, 1901.

Pteridophyta.—The *Pteridophyta*, or, as they are frequently called, the Vascular Cryptogams, were treated of in the ninth edition of this work under the title FERNS, since the majority of the existing plants of this great subdivision of the vegetable kingdom belong to that group. The importance and interest of the other Pteridophytes, of which the Club-mosses and Horsetails are the most familiar examples, depend largely on the fact that they are the surviving representatives of large groups of plants which flourished in earlier geological periods. In order to understand the relationship of those now living, the extinct forms must be taken into consideration, and so far as is possible must be included in the general scheme of classification. For a fuller description of the extinct Vascular Cryptogams than can be given here the articles on the Palaeozoic and Mesozoic floras should be consulted, and with regard to the living forms, the article on FERNS already mentioned. The investigations since 1879 have resulted in an increase of our knowledge of the details of morphology and natural history of these plants, which has placed many of the problems presented by them in a new light. Thus, though points treated fully in the ninth edition of the *Encyclopaedia Britannica* will only be referred to here, it is necessary to review the whole subject. For fuller information regarding the anatomy of the sporophyte and explanation of anatomical terms, the article on ANATOMY OF PLANTS should be consulted.

Life-history.

The relation which exists between the two alternating stages or generations, which together constitute the complete life-cycle of all plants higher than the *Thallophyta*, is perhaps the most natural characteristic of the *Pteridophyta*. From the germinated spore of a fern-plant a small, flat, green organism is developed; this is the prothallus (gametophyte, sexual generation). As the result of fertilization of the ovum produced by this, the fern-plant (sporophyte, asexual generation) originates; from it spores are

ultimately set free, with the germination of which the life-history again commences. The point common to all *Pteridophyta* is that from the first the gametophyte is an independent organism, while the sporophyte, though in the first stages of its development it obtains nutriment from the prothallus, becomes physiologically independent when its root develops. This independence of the two generations for the greater part of their lives distinguishes

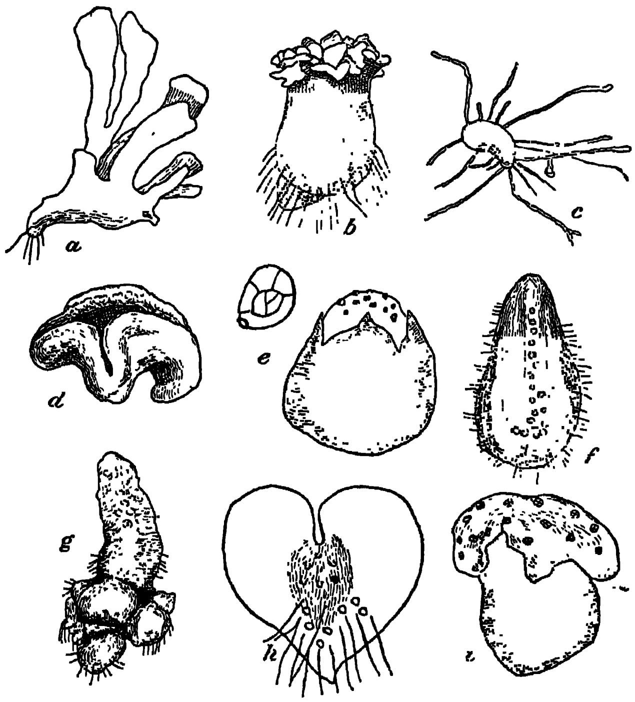

Fig. 1.—Diagrammatic sketches of prothalli of—*a*, Equisetum; *b*, Lycopodium cernuum; *c*, L. Phlegmaria; *d*, L. clavatum; *e*, Selaginella; *f*, Botrychium Virginianum; *g*, Helminthostachys; *h*, a Fern; *i*, Salvinia.

this group on the one hand from the *Bryophyta* (in which the sporophyte is throughout its life attached to the gametophyte), and on the other hand from the Gymnosperms and Angiosperms (in which the more or less reduced gametophyte remains enclosed within the tissues of the sporophyte). The gametophyte, which is usually dorsiventral, though in some cases radially symmetrical, is a small thallus attached to the soil by rhizoids. In structure it is equally simple, being composed of parenchymatous tissue without any clearly marked conducting system. Usually it grows exposed to the light and contains chlorophyll, but subterranean saprophytic prothalli also occur. In the heterosporous forms the gametophyte is more or less reduced. The reproductive organs ultimately produced on the same or on different individuals are of two kinds, the antheridia and archegonia; the origin of both is from single superficial cells of the prothallus. The antheridium at maturity consists of a layer of cells forming the wall which encloses a group of small cells; from each of the latter a single motile spermatozoid originates. The archegonium consists of a more or less projecting neck, and the venter, which is usually enclosed by the tissue of the prothallus. A central series of cells can be distinguished in it, the lowest of which is the ovum; above this come the ventral canal cell and one or more canal cells. When the archegonium has opened by the separation of the terminal cells of the neck, the disintegration of the canal cells leaves a tubular passage, at the base of which is the ovum. Down this canal the spermatozoid, which in the Ferns has been shown to be attracted by reason of its positive irritability to malic acid, passes and fuses with the ovum. After fertilization the latter surrounds itself with a cell-wall and develops into the sporophyte. The early segmentation of the embryo

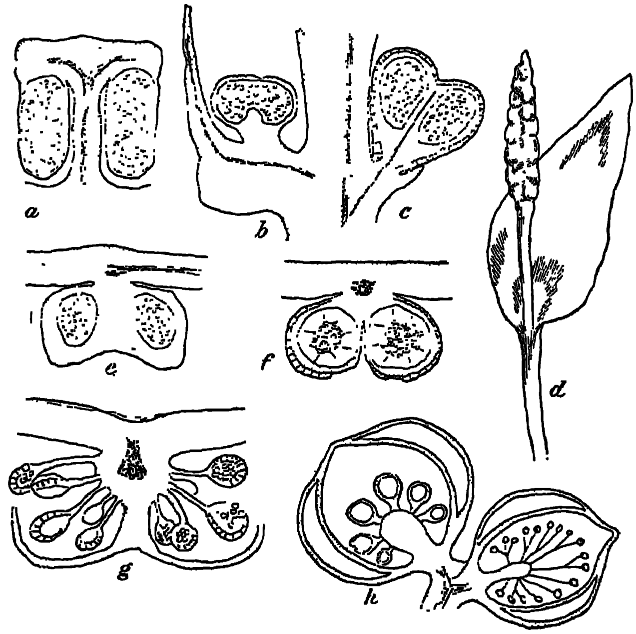

Fig. 2.—Diagrammatic sketches of spore-producing members of—*a*, Equisetum; *b*, Lycopodium; *c*, Psilotum; *d*, Ophioglossum; *e*, Kaulfussia; *f*, Angiopteris; *g*, Nephrodium; *h*, Salvinia. (All except *d* represent vertical sections of sporangiophore or sorus.)

differs in the several groups, but usually the first leaf or leaves, the apex of the stem, and the first root are differentiated early, while a special absorbent organ (the foot) maintains for some time the physiological connexion between the sporophyte and the prothallus. The sporophyte is always highly organized both as regards form and structure. Root, stem, and leaf can be distinguished even in the simplest forms, and the plant is traversed by a well-developed vascular system. The reproductive organs of the sporophyte are the sporangia, within which the spores are produced; these are often borne on or in relation to leaves, which may be more or less distinct from the foliage leaves in form and structure. The cells of the wall of the sporangium are usually so constructed as to determine the dehiscence of the sporangium and the liberation of its spores. The spores produced in each sporangium vary from very many to a single one in the case of some heterosporous forms. These latter bear spores of two kinds, microspores and megaspores, in separate sporangia. From the microspore an extremely reduced male prothallus, and from the megaspore the female prothallus, develops. The spores of the homosporous Vascular Cryptogams are usually of small size; the prothalli produced from them usually bear both antheridia and archegonia, though under special conditions an imperfect sexual differentiation may result. The complete life-history, with its regular alternation of gametophyte and sporophyte, is now known in all except a few rare genera of recent *Pteridophyta*, and will be described in connexion with the several groups.

The *Pteridophyta* as known at present comprise four main subdivisions, the *Equisetales*, *Sphenophyllales*, *Lycopodiales*, and *Filicales*. The *Sphenophyllales* are only known in a fossil state, while the other three include both fossil and recent representatives.

Classification.

The systematic arrangement of the Vascular Cryptogams for the purposes of identification and description necessarily remains unchanged, while the comparative morphology is being more fully worked out. But modifications in the order of placing the natural groups are of importance in

expressing the results of such investigations. Such a scheme may be placed here in a tabular form before entering on the consideration of the life-history, natural history, morphology, and classification of the several groups:—

Pteridophyta.

I. EQUISETALES .	*Equisetaceæ.*	
	Calamariaceæ.	
II. SPHENOPHYLLALES	*Sphenophyllaceæ.*	
	Cheirostrobaceæ.	
III. LYCOPODIALES .	*Lycopodiaceæ.*	
	Psilotaceæ.	
	Selaginellaceæ.	
	Lepidodendraceæ.	
	Isoetaceæ.	
IV. FILICALES .	*Ophioglossaceæ.*	
	Filicaceæ.	*Marattiaceæ.*
		Osmundaceæ.
		Schizæaceæ.
		Gleicheniaceæ.
		Matoniaceæ.
		Loxsomaceæ.
		Hymenophyllaceæ.
		Cyatheaceæ.
		Polypodiaceæ.
	Hydropterideæ.	*Salviniaceæ.*
		Marsileaceæ.

I. EQUISETALES.—The plants of the single living genus *Equisetum*, which vary in height from a few inches to forty feet, have subterranean rhizomes, from which the erect shoots arise. The general appearance and construction of the shoot, with its elongated hollow internodes and whorls of united leaves inserted at the nodes, have been described in the article on FERNS. The leaves of successive whorls alternate with one another, and this applies also to the branches which arise in the axil of the leaf sheath. In most species many of these buds, which alternate with the leaves, remain dormant, but in others the aërial shoots are copiously and repeatedly branched. In some species branches of the rhizome with tuberous internodes are formed, which serve as a means of vegetative reproduction. The roots which arise from the base of the lateral buds remain undeveloped on the aërial stem. The general course of the vascular bundles in the stem of *Equisetum* is figured and described in the article on FERNS. The young stems, and the older stems of certain species, are clearly monostelic, but in other species an inner and outer endodermis may be present, or an endodermal layer surrounds each bundle. The vascular bundles themselves are collateral, the xylem consisting of the protoxylem, towards the centre of the stem, and two groups of xylem, between which the phloëm is situated; the protoxylem elements soon break down, giving rise to the carinal canal. There is no secondary thickening except at the node in *E. maximum*, where some short tracheides, arranged in radial rows, arise from a cambium. The stems, the surface of which exhibits a number of ridges with intervening furrows, perform the greater part of the work of assimilation. The chlorophyll-containing tissue reaches the surface at the sides and base of the furrows, where stomata of peculiar form occur in the epidermis, while subepidermal strands of sclerenchyma occupy the ridges. In the cortical tissue beneath each furrow a wide intercellular space is present running the length of the internode, and called the vallecular canal. The central cylinder of the root, in which there are several xylem and phloëm strands, has around it a two-layered endodermis, the inner layer of which appears to take the place of a pericycle. The sporangia are borne upon lateral outgrowths of the axis (the sporangiophores), which arise in whorls and are associated in definite strobili or cones; at the base of the cone an outgrowth of the axis like a rudimentary leaf sheath (the annulus) is present. Each sporangiophore consists of a stalk expanding into a peltate disc of hexagonal outline; from the inner surface of the latter six to nine sporangia hang parallel with the stalk. The single vascular bundle supplies a branch to the base of each sporangium. The latter arises from a number of superficial cells, the cells destined to form the spores being derived from a single one of these. A tapetal layer is derived from the cells surrounding the sporogenous group, and the arrest of a number of the spore mother-cells further contributes to the nourishment of the remainder, each of which gives rise to four spores. The outermost layer of the cell-wall of the ripe spore splits along spiral lines, giving rise to the elaters; these two long strips of wall, attached by their middle points to the spore, tend to straighten out in dry and close round the spore in damp air. They thus assist in the opening of the sporangium, which takes place by a slit on its inner face. Further, several spores will be likely to germinate together owing to their elaters becoming entangled; a fact of some importance, since the antheridia and archegonia, though occurring sometimes on the same prothallus, are more often borne on separate individuals. The prothali contain abundant chlorophyll, and are dorsiventral. Those that bear the antheridia are the smaller, and are either filamentous, or flattened, with the margin irregularly lobed. The antheridia are deeply sunk in the tissue; the spermatozoids consist of a spiral of two or three coils, the numerous cilia being attached to the pointed anterior end. The female prothalli, which are sometimes branched, consist of a thick cushion bearing thin, erect, lateral lobes, at the base of which the archegonia are situated. The necks of the latter are short, the central series of cells consisting of ovum, ventral canal cell, and one or two canal cells. The half of the embryo directed towards the archegonial neck gives rise to the apex of the stem and a sheath of three leaves, the other half to the small foot and the primary root. The first shoots are of limited growth, being replaced by lateral branches, which gradually acquire the number of leaf teeth characteristic of the species.

Fossil species, some of which attained a great size, are known, to which the name *Equisetites* is given, since they appear to be closely allied to the existing forms. Two other extinct genera, *Phyllotheca* and *Schizoneura*, may be mentioned here. Abnormal specimens of *Equisetum* in which the strobilus is interrupted by whorls of leaves are of interest for comparison with the fructification of *Phyllotheca*. The most important and best known of the extinct *Equisetales* are, however, the Calamites, for a detailed account of which the article PALÆOBOTANY: *Palæozoic*, must be consulted. In the primary structure of the stem the Calamites present many points of resemblance to *Equisetum*, but secondary thickening went on in both stem and root. These plants, which appear to have grown in swampy soil, thus attained the dimensions of considerable trees. The leaves, which were of simple form (except in *Archæocalamites*, where they forked), were inserted in whorls at the nodes; they were either free from one another or cohered by their bases into a sheath. The branches alternated in position with the leaves, and sprang from just above the insertion of the latter. Some of the branches terminated in cones, which present a general similarity to those of *Equisetum*. This similarity is closest in *Archæocalamites*, an ancient type found in Upper Devonian rocks; in this the strobilus consists of peltate sporangiophores inserted in whorls on the axis. In the other Calamarian strobili known the whorls of sporangiophores are separated by whorls of bracts. In some the sporangiophores stood midway between the sterile whorls, while in others they approached the whorl above or below. There is a close resemblance between these sporangiophores and those of *Equisetum*, but as a

rule only four sporangia were borne on each. Some Calamites were heterosporous, sporangia with microspores and megaspores being found in the same cone.

Our knowledge of the extinct *Equisetales*, full as it is with respect to certain types, does not suffice for a strictly phylogenetic classification of the group. The usual subdivision is into *Equisetaceæ*, including *Equisetum* and *Equisetites* (with which *Phyllotheca* and *Schizoneura* may be provisionally associated), and *Calamariaceæ*, including *Calamites* and *Archæocalamites*.

II. Sphenophyllales.—The two very distinct genera *Sphenophyllum* and *Cheirostrobus*, included in this group, are known only from the Palæozoic rocks. Though the high specialization of this ancient group of plants renders the determination of their natural affinities difficult, indications are afforded by anatomy and the morphology of the strobilus. In general appearance the species of *Sphenophyllum* (the remains of *Cheirostrobus* known do not allow of any idea of its habit being formed) present some resemblances to the *Equisetales*. The long, sparingly branched stem bore at the somewhat swollen nodes whorls of six to eighteen wedge-shaped or linear leaves, which did not alternate in successive whorls. Both the broader and narrower leaves may be more or less deeply divided, and both forms may occur on the same shoot. From the relation of the thickness of the stem to its length it may be inferred that the shoots of *Sphenophyllum* derived support from adjoining plants. Without entering into detail regarding the anatomy, it may be stated that secondary thickening took place in both genera. The single stele in the stem consisted of the phloëm surrounding a solid central strand of xylem, the groups of protoxylem being situated at the projecting angles. In *Sphenophyllum*, in which the transverse section of the xylem is triangular, there were three or six protoxylem groups; in *Cheirostrobus* they were more numerous. The anatomy of the stem is thus very unlike that characteristic of the *Equisetales*, and presents essential points of resemblance to the *Lycopodiales*, especially the *Psilotaceæ*. The general morphology of the cones, on the other hand, points to an affinity with the *Equisetales*. The cone of *Sphenophyllum* consisted of an axis bearing at the nodes whorls of bracts, united below into a sheath. The overlapping bracts afforded protection to the sporangia, which were borne on sporangiophores springing from the upper surface of the coherent bracts near their origin from the axis; two sporangiophores usually arose from each bract, and sometimes adhered to its upper surface for some distance. Each bent round at the upper end, and bore one or two sporangia on the side turned towards the axis. The mature sporangium had a wall of a single layer of cells, which were larger towards the base, where they continued into the epidermis of the sporangiophore. In other species of *Sphenophyllum*, which are known only as impressions, single sporangia, or groups of four, appear to have been inserted directly on the upper surface of the bracts. In *Cheirostrobus* a similar relation of sporangiophores to bracts existed, but here each bract was divided into three segments. From each segment, near its base, a stalked peltate sporangiophore arose; this bore four sporangia, which hung parallel to the stalk. That these three sterile segments, with their sporangiophores, are together comparable to one of the bracts of *Sphenophyllum*, with its sporangiophores, is shown by the vascular supply in each case being derived from a single leaf-trace. So far as is at present known, the *Sphenophyllales* were homosporous. The differences between the two genera described above are sufficiently marked to justify the division of the *Sphenophyllales* into the two orders *Sphenophyllaceæ* and *Cheirostrobaceæ*. A consideration of the characters of both shows that resemblances suggesting actual relationship exist between this group and the *Equisetales* and *Lycopodiales*, between which they are here placed. It has been suggested that the *Sphenophyllales* may have sprung from a very old stock which existed prior to the divergence of the latter groups. So long, however, as our knowledge of these three phyla is confined, as at present, to specialized forms, the nature of the relationship between them must remain hypothetical.

III. Lycopodiales.—The living representatives of this group, for a general description of which the article Ferns should be referred to, are of small size compared with the related plants which lived in Palæozoic times. A large proportion of the living species are tropical, though others have a wide distribution. As general characteristics of the *Lycopodiales*, the simple form of the leaves, which are generally of small size, and the situation of the sporangia on the upper surface of the sporophylls, which are often associated in cones, close to their insertion on the axis, may be mentioned; there are both homosporous and heterosporous forms, the prothalli exhibiting corresponding differences. Before considering the characteristics of the several orders of this phylum, it is of interest to recognize in many of the surviving forms peculiarities in mode of life, to which we may reasonably ascribe their success in the struggle for existence or their escape from severe competition. Thus *Tmesipteris* and many species of *Lycopodium* are epiphytic, *Psilotum* is a partial saprophyte, and many species of *Isoetes* are aquatic. Vegetative reproduction is effected in various ways: by the separation of the branches of a creeping stem in some *Lycopodia*, the persistence through the winter of the apex of the shoot in *L. inundatum*, the formation of leafy bulbils on the aërial stem of *L. Selago* and others, and of small gemmæ on the rhizome of *Psilotum*. A highly specialized means of vegetative reproduction is seen in the tubers of *Phylloglossum* and the embryos of some Lycopods. The modifications shown by the gametophyte of *Lycopodium* will be described below. All such special relations of the plant to its environment, which might be expected in the few forms of a large group which had persisted beyond the others, are less marked in the genus *Selaginella*. It would appear as if the latter was more suited to the conditions of the existing flora, and many of the specific forms within it may rather be regarded as recently evolved than as simply persistent.

Lycopodiaceæ.—This order contains the two genera *Phylloglossum* and *Lycopodium*; the former has a single species, while nearly one hundred species of *Lycopodium* are known. Erect and creeping terrestrial plants and pendulous epiphytes occur in the latter genus. The simple leaves, which are of small size and do not possess a ligule, are arranged spirally around the branched stem in the majority of the species. The roots of the erect forms often grow downwards in the cortex of the stem to reach the soil. The anatomy of *Lycopodium* presents considerable variety in detail, but the stem is always monostelic and the development of the xylem centripetal, the protoxylems being situated at the periphery of the stele; pericycle and endodermis surround the stele, and the wide cortex may be more or less sclerenchymatous. The central cylinder of the root often shows a striking resemblance to that of the stem. The *Lycopodiaceæ* are homosporous. The spores are formed in sporangia of considerable size, situated on the upper surface and near the base of the sporophylls. The latter may differ from the foliage leaves and be arranged in definite cones, or the two may be similar and occupy alternate zones of a shoot with continued growth; sometimes rudiments of sporangia are found at the bases of the leaves. In the development of the sporangium the sporogenous tissue is derived from a number of superficial cells by divisions parallel to the surface. The tapetum is derived from the layer of cells surrounding the sporogenous group. Short trabeculæ of sterile tissue have been found to project into the cavity of the sporangium of some species. The spores, when liberated by the dehiscence of the sporangium, give rise to the prothallus, which is now, owing mainly to the investigations of Treub and Bruchmann, known in a number of tropical and temperate species. In habit

and mode of life of the prothallus these present striking differences, which may be correlated with the situations inhabited by the sporophyte, and are perhaps to be regarded as adaptations which have enabled the species to survive. Thus in *L. cernuum* and others the prothallus is green and grows on the surface of the soil; in the species living on the moors it is subterranean and saprophytic, though capable of developing chlorophyll when exposed to light; while in *L. Phlegmaria* and other epiphytic forms the prothallus consists of fine branches growing saprophytically in rotting wood. A comparison of these various types would appear to indicate that the primitive form of prothallus in the genus was radially symmetrical and contained chorophyll. The prothalli of *L. cernuum* come nearest to this; in them the meristem forms a zone slightly below the summit, which may bear a number of green lobes. The different forms of the prothallus found in *L. Selago* give an idea of how the more extremely modified types could be derived from such a prothallus as that of *L. cernuum*. All the saprophytic prothalli contain an endophytic fungus in definite layers of their tissue. The antheridia and archegonia are produced above the meristematic zone, and are more or less sunk in the tissues of the prothallus. The most important difference in the sexual organs concerns the length of the archegonial neck; this is shortest and has only a single canal cell in *L. cernuum*, while in *L. complanatum* it is longer than in any other Vascular Cryptogam, and contains a number of canal cells. The spermatozoids are biciliate. The embryo in *L. cernuum* and other forms with superficial green prothalli is attached to the prothallus by a small foot, and develops at first as a tuberous body (the protocorm) bearing rhizoids; this forms a number of simple leaves, and upon it the apex of the shoot arises later. In the saprophytic forms the protocorm is absent, and in some of them the foot is of large size. When new individuals of species which possess a protocorm arise vegetatively from the leaves or roots of young plants, the protocorm appears in the young sporophyte. This fact leads to the consideration of *Phylloglossum*, which resembles the embryo of *Lycopodium cernuum* in so many respects that it has been spoken of as a permanently embryonic form of Lycopod: it is in some respects the simplest existing Pteridophyte. Its prothallus resembles that of *L. cernuum*, but wants the crown of assimilating lobes. The plant is reproduced by tubers, which resemble the protocorm in bearing first a number of protophylls and later the upright shoot with its single terminal strobilus. The sporangia agree with those of *Lycopodium* in structure and position.

Psilotaceæ.—The two genera included in this order are somewhat isolated among the *Lycopodiales*. In both *Psilotum* and *Tmesipteris* the functions of the root-system, which is completely absent, are performed by leafless rhizomes bearing absorbent hairs and inhabited by an endophytic fungus. *Psilotum* lives epiphytically or in soil rich in humus, while *Tmesipteris* is epiphytic (and, it has been suggested, partially parasitic) upon stems of tree ferns: the former has small scale-like leaves; those of the latter are of considerable size. The stem is monostelic, the protoxylem groups being towards the periphery of the xylem, the development of which is thus centripetal; the centre of the stele is occupied by sclerenchymatous tissue. The leaves, which bear the sporangia, are bilobed and do not form definite cones, but alternate in irregular zones with the foliage leaves. The sporangia of the *Psilotaceæ* are associated in synangia, which occupy the same position relatively to the sporophyll as the single sporangium of *Lycopodium*. The careful study of the development of the synangium of *Tmesipteris*, which consists of two loculi, and of *Psilotum*, which consists of three, has shown that their structure can be adequately explained as originating by the septation of a single sporangium resembling that of *Lycopodium*. Other views of the nature of the *Psilotaceous* synangium are, however, possible—one, which regards the sporophyll and synangium as corresponding to the bract and sporangiophores in *Sphenophyllum*, being of special interest, on account of the resemblance in anatomy between the *Psilotaceæ* and the *Sphenophyllales*. There is some reason to believe that the prothallus of *Psilotum* resembles some *Lycopodium* prothalli, but conclusive evidence is wanting; that of *Tmesipteris* is unknown.

Selaginellaceæ.—The single genus of this order (*Selaginella*) contains between three and four hundred species. There is considerable diversity among them as regards external form, the majority having dorsiventral aërial shoots with dimorphic leaves, while in others the shoots are radially symmetrical and the leaves alike. The stem contains one, two, or several steles; in one species the stele is tubular. The phloëm completely surrounds the xylem, which usually develops from two protoxylem groups. In the aërial stem of the British species (*S. spinosa*) the radial stele has a number of protoxylem groups arranged round the periphery, much as in *Lepidodendron*. The cells of the endodermis are developed as trabeculæ, which traverse the continuous air-space surrounding each stele. The simple, uni-nerved leaves have a ligule near the base; the base of the ligule is somewhat sharply marked off from the other tissues of the leaf. In some species a depression of the leaf-surface encloses the ligule, regarding the function of which little is known. The roots, the stele of which is monarch, may arise directly from the stem, or are borne on rhizophores, which spring from the shoot at the point of branching, and root on reaching the soil. In structure they resemble the roots, but their morphological nature is uncertain. The sporophylls are arranged radially in the cones, which are terminal on the branches. A single sporangium is borne on the axis just above the insertion of each sporophyll. *Selaginella* is heterosporous, the megasporangia being often found towards the base of the cone. The development of the micro- and mega-sporangia is the same up to the stage of isolation of the spore mother-cells. The sporogenous tissue, which is referable to several archesporial cells, is surrounded by a tapetum, mostly derived from the sporogenous group. In the microsporangium all the mother-cells undergo the tetrad division, giving rise to the numerous microspores. In the megasporangium, on the other hand, the four megaspores, which arise from a single mother-cell, are nourished at the expense of the other sporogenous cells and of the tapetum. On germination the microspores give rise to a reduced prothallus, consisting of the small cell first cut off and a wall of cells enclosing two to four central ones; from these latter the biciliate spermatozoids originate. The megaspore becomes filled with the female prothallus, the formation of cell-walls commencing at the pointed end of the spore, where from the first the nuclei are more numerous, and later extending to the base. The surface of the prothallus which is exposed when the thick wall of the spore is ruptured may produce a few rhizoids; upon it the archegonia, consisting of a short neck and the central series of ovum, ventral canal cell, and canal cell, arise. After fertilization the embryo forms a short suspensor; the apex of the stem, with a leaf on each side of it, is first distinguishable; at the base of this is the foot; while the root arises on the farther side of the latter. Thus the position of the foot in *Selaginella* is different from what obtains in the other Vascular Cryptogams. A point of interest in this heterosporous genus is that the formation of the prothallus may commence before the megaspore is liberated from the sporangium.

Lepidodendraceæ.—This order includes only extinct forms, the best known of which are the plants placed in the genera *Lepidodendron* and *Sigillaria*. These plants, a fuller description of which must be sought in the article PALÆOBOTANY: *Palæozoic*, underwent secondary increase in thickness and attained the size of large trees; the aërial stem was more or less branched dichotomously. The leaves, which were of simple form and provided with a ligule, were, as the leaf-scars on the stem show, variously arranged. In *Sigillaria* the latter form vertical rows, while in *Lepidodendron* the arrangement is a complicated spiral. The stem had a single stele, the primary xylem of which was polyarch and centripetally developed. The upright stems were attached to the soil by a number of dichotomously branched members (*Stigmaria*), which, whatever their morphological nature may be, appear to have performed the function of roots: they have numerous cylindrical appendages, which penetrated the soil on all sides. The cones, which in some instances at least were heterosporous, presented a general resemblance to those of *Lycopodium* and *Selaginella*, a single sporangium being situated on the upper surface of each sporophyll. The cavities of the large sporangia were sometimes traversed by trabeculæ of sterile tissue resembling those found in *Isoetes*. In some of the heterosporous forms (*Lepidocarpon*) the sporangia were sometimes surrounded by an integument; and since only a single megaspore attained maturity, the structure of the megasporangium suggests a comparison with an ovule.

Isoetaceæ.—The single genus (*Isoetes*) contains about fifty, mostly aquatic, species, though a few are amphibious or terrestrial. The plants present considerable uniformity in general habit, consisting of a short, unbranched stem, bearing the closely crowded awl-shaped leaves, which in the larger species attain the length of a foot. Each leaf bears a ligule resembling that of *Selaginella* in structure and position. The stem is monostelic, the centre of the stele being occupied by a mass of short tracheides; but little can be said as to the primary structure of the central cylinder, which appears to be reduced. A meristematic zone forms, a short distance outside the xylem, from which secondary tissue is developed both internally and externally; that to the inside contains both xylem and phloëm elements. By the unequal development of the secondary cortex the stem becomes two- or three-lobed; the roots, which branch dichotomously, spring from the furrows between the lobes. The leaves have a single main bundle, and in the mesophyll are four longitudinal series of large intercellular spaces separated by transverse diaphragms. The sporangia, which are situated singly on the adaxial surface of the leaves, between their insertion on the stem and the ligule, arise from a considerable number of epidermal cells. The cells composing the young sporangium are at first similar, but ultimately become differentiated into sterile trabeculæ, which may stretch from the inner to the outer wall, and the mother-cells of the spores. The latter are more numerous in the microsporangium than in the megasporangium. The tapetal layer is partly formed from the sporangium wall and partly as a layer covering the trabeculæ. The

spores, which are set free by the rotting of the sporangial wall, germinate much as in the case of *Selaginella*, though the similarity may be a case of independent resemblance. Important points of difference are found in the multiciliate spermatozoids, and in the embryo, which has no suspensor.

The several orders of *Lycopodiales* described above, while presenting a number of features in common, are distinctly isolated from one another. A natural classification of such specialized plants can only be obtained when the extinct forms are more fully known. What is known at present, while it does not indicate the phylogeny of the *Lycopodiales*, at least shows that such living orders as *Lycopodiaceæ* and *Selaginellaceæ* cannot be regarded as forming a linear series. The difficulty is increased when it is borne in mind that the small surviving forms probably have a long geological history, and may have coexisted with the *Lepidodendraceæ*. For these reasons no attempt has been made to arrange the orders in larger divisions, since such a division as that of the ligulate and eligulate forms, while convenient for practical purposes, may not express the phylogeny of the group. The resemblances between the outstanding order *Psilotaceæ* and the *Sphenophyllales* have been noted above, and it remains to be mentioned that the *Isoetaceæ* have been regarded as more nearly allied to the *Filicales* than to the forms near which they are here placed.

IV. Filicales.—The article on Ferns dealt so much more fully with the Ferns than with the other Vascular Cryptogams that it is sufficient to refer to it for a general account of their life-history, structure, and habit, and the principles on which they are classified. The classification in that article was that of the *Synopsis Filicum*, the standard systematic work on these plants; the modifications in general arrangement adopted below are the expression of the progress which has been made in tracing the phylogeny of the group. One main departure must be specially noted here. The *Ophioglossaceæ* and *Marattiaceæ*, united in the article on Ferns as *Stipulatæ*, though possessing some characters in common, do not appear to constitute a natural group, and have been separated; the former are placed by themselves, but, pending further evidence as to their true relationship, are still included in the *Filicales*, while the latter are grouped with the rest of the homosporous ferns as *Filicaceæ*. The heterosporous forms are treated by themselves as *Hydropterideæ*, though further research will probably indicate more precisely their relationship to the *Filicaceæ*.

Ophioglossaceæ.—The peculiarities of this small order of *Pteridophyta* render their systematic position a matter of some doubt, especially in the absence of evidence as to their geological history. In the three genera, *Ophioglossum*, *Botrychium*, and *Helminthostachys*, there is an underground rhizome, from which one leaf or a few leaves with sheathing bases are produced annually; the roots arise in more or less definite relation to the insertion of the leaves. The latter are simple, or irregularly lobed in *Ophioglossum*, more or less compoundly pinnate in *Botrychium*, and palmately pinnate in *Helminthostachys*. The fertile branch or branches are situated on the adaxial surface of the leaves, and may be simple, as in *Ophioglossum*, or more or less compound, the degree of branching in the sterile and fertile segments exhibiting a general parallelism. The stem is monostelic, the arrangement of the xylem and phloëm being collateral. The endodermis and pericycle surround the whole stele in *Botrychium* and *Helminthostachys*; in *Ophioglossum* each bundle has a separate sheath. Well-marked secondary thickening occurs in *Botrychium*. In the roots of *Ophioglossum* and *Botrychium* and in the first formed roots of *Helminthostachys* an endophytic fungus is present, forming a mycorhiza—the stele in the larger roots has the usual radial arrangement of xylem and phloëm. The morphology of the fertile spike is a disputed question, upon the answer to which the systematic position of the *Ophioglossaceæ* largely rests. The spike is most simple in *Ophioglossum*, where it bears on each side a row of large sporangia, which hardly project from the surface, the vascular bundles occupying a central position. In the young spike, which arises when the leaf is still very small, a band of tissue derived from superficial cells is distinguishable along either side; this sporangiogenic band gives rise to the sporogenous groups, the sterile septa between them, and the outer walls of the sporangia. The spike of *Helminthostachys* corresponds to that of *Ophioglossum*, but in it the sporangia are borne on two lateral rows of branched sporangiophores. The sporangia resemble those of *Botrychium*, which project from the ultimate subdivisions of the branched spike; each is developed from a number of cells, the sporogenous tissue arising from a single cell. Two diverse views of the morphology of the fertile spike in these plants have been entertained which must be mentioned. The older view was that it was a fertile segment of the leaf; and though its ventral position presents a difficulty, this must be regarded as a possible explanation when the analogous case of the *Marsileaceæ* is taken into consideration; the occasional occurrence of sporangia on the lamina in *Botrychium* has also been regarded as supporting it. On the other hand, the spike has been explained as due to the elaboration of a single sporangium occupying a similar position with regard to the leaf as in the *Lycopodiales*, and evidence of considerable weight has been brought forward in support of this interpretation. The important bearing of this question on the relationship of the *Ophioglossaceæ* to the phyla of the *Filicales* and *Lycopodiales* will be obvious. The *Ophioglossaceæ* are homosporous, and the prothalli, which are known in two species of *Ophioglossum* and *Botrychium*, and in *Helminthostachys*, are subterranean and saprophytic. The prothallus of *O. pedunculosum*, as observed by Mettenius, subsequently reached the surface and produced green lobes; those of the other species known are wholly saprophytic, and contain an endophytic fungus. They thus present a general, but probably homoplastic, resemblance to the prothalli of certain *Lycopodia*. Important points of difference exist, however, in the apical position of the meristem of the Ophioglossaceous prothalli, in the presence of a basal cell to the archegonium, and in the multiciliate spermatozoids. In these respects, and in the absence of a suspensor from the embryo, the *Ophioglossaceæ* approach the *Filicaceæ*. The position of the *Ophioglossaceæ* can at present only be regarded as an open question, in considering which the possible antiquity of the group must be borne in mind.

Filicaceæ.—This order of *Pteridophyta* differs from the others in being well represented in our present flora by forms, many of which can be regarded, not as archaic types which have persisted to the present day, but as having been evolved in comparatively recent periods. The external form of the Ferns having been fully dealt with in the article already mentioned, it will suffice to refer to the more striking adaptive modifications in the gametophyte and sporophyte, and to certain effects of altered external conditions which have been ascertained experimentally. The dorsiventrality of the prothallus has been shown to depend mainly on the illumination, the filamentous form being retained in feeble light; a similar result is obtained when the prothalli are cultivated in water. These facts may have a bearing on the filamentous prothalli of some *Hymenophyllaceæ*. The reproduction of the prothallus by gemmæ in species of *Trichomanes*, *Vittaria*, and *Monogramme*

is another interesting adaptation; the perennial prothallus of *Gymnogramme leptophylla* is described in the article on FERNS. The phenomena of apogamy and apospory, which have now been observed in a number of Ferns, may be mentioned here. In the former the prothallus produces one or more fern-plants vegetatively, the projection which develops into the sporophyte in many cases occupying the position of an archegonium. In some apogamous Ferns sporangia may occur on the prothallus, and the vegetative organs of the sporophyte may also occur singly. In apospory the converse phenomenon is seen, the gametophyte springing vegetatively from the sporangium, receptacle of the sorus, or leaf margin of the fern-plant. In a number of cases, though not in all, apospory appears to be correlated with a failure of the sporangia to develop, and a similar correlation between apogamy and the prevention of sexual reproduction appears probable. The adaptations in the vegetative organs of the sporophyte are similar to those in the Flowering Plants. Thus there are a few Ferns which climb, others are water plants, while many, especially those which live as epiphytes, are more or less xerophytic. Some of the epiphytic forms (*Polypodium quercifolium, Platycerium*) have strongly dimorphic leaves, the sterile leaves serving in some cases to catch falling débris, and thus to provide the plant with soil. Lastly, the symbiotic relation between the plant and ants is found in Ferns, the rhizome of *Polypodium carnosum* containing cavities inhabited by these insects. The existence of these myrmecophilous Ferns suggests a possible explanation of the nectaries on the leaves of some other species, such as the common Bracken.

The main existing groups of the *Filicaceae* may now be briefly described, with special reference to the characters of gametophyte and sporophyte, which have been found of value in determining affinities.

Marattiaceae.—These are ferns of considerable size, the large leaves of which are borne on a short, erect, swollen stem (*Angiopteris, Marattia*), or arise from a more or less horizontal rhizome (*Danaea, Kaulfussia*). The leaves, at the base of which are two large stipule-like outgrowths, have a thick leaf-stalk, and are simple or simply pinnate in *Danaea*, pinnate in *Archangiopteris*, bi- to tri-pinnate in *Marattia* and *Angiopteris*, and digitately lobed in *Kaulfussia*. The stem, from the ground tissue of which sclerenchyma is absent, has a complicated system of steles arranged in concentric circles; the thick roots, the central cylinders of which have several alternating groups of xylem and phloëm, arise in relation to these. The pinnae, except in a few filmy forms, are thick; in *Kaulfussia* large pores derived from stomata occur in the epidermis. The sori are borne on the under surface of the pinnae, usually in a single row on either side of the midrib, but in *Kaulfussia* dotted over the expanded lamina. The large sporangia, each of which originates from a number of superficial cells, are here incompletely separated from one another and arranged in a single circle forming a synangium. The association is closest in *Danaea*, where the individual sporangia of the elongated sorus, which is sunk in a depression of the leaf, open by pores; in *Marattia* and *Kaulfussia* they dehisce by slits on the inner face; while in *Angiopteris* they are almost free from one another. The spores produce a green prothallus of large size, the sexual organs of which hardly project from the surface. The cotyledon and stem grow up vertically through the prothallus, the root turning downwards into the soil.

Osmundaceae.—The two genera of this group, *Osmunda* and *Todea*, have thick erect stems, covered with the closely crowded leaf bases. The stem is monostelic, the vascular tissues being separated into curved groups comparable with collateral vascular bundles, which surround the pith. The somewhat thick roots are diarch. The leaves are large and pinnate; their lamina is usually thick, though filmy species of *Todea* occur. The leaf-base shows indications of stipular outgrowths. In *Todea* the sori, each of which consists of a single circle of bulky sporangia, are borne on the under surface of the pinnae. In *Osmunda* the region of the leaf which bears the sporangia has its lamina little developed; the leaf thus bears sterile and fertile pinnae, or, as in *O. cinnamomea*, sterile and fertile leaves may be present. The sporangia originate from single cells, though surrounding cells may contribute to the formation of the stalk. The latter is thick and short, and the wall of the sporangium, which opens by a median slit, has a group of thick-walled cells at the summit, forming the annulus. The prothalli are similar to those of the other *Filicaceae*, but more massive; the same may be said of the archegonia and antheridia, which, however, project more than in the preceding group.

Schizaeaceae.—The anatomy of the stem differs in the four recent genera of this order, and presents a series possibly illustrating the origin of a number of concentric steles from a solid stele, the intermediate step being represented by those forms in which the central cylinder is tubular. The sporangia are borne singly or in sori of two or three on the margin or under surface of leaves, the fertile pinnae of which differ more or less from the sterile segments. The sporangium is of considerable size, and dehisces by a median slit, the annulus being a more or less definitely limited horizontal ring of cells near the apex. The prothallus and sexual organs may resemble those of the *Polypodiaceae*; in *Aneimia* and *Mohria* the prothallus, though flattened, is not bilaterally symmetrical, the growing point being on one side; a filamentous type of prothallus is known in *Schizaea*.

Gleicheniaceae.—These forms have a horizontal rhizome, from which simply pinnate leaves arise in *Platyzoma*, while *Gleichenia* bears compound pinnate leaves with continued apical growth. The rhizome usually has a solid central cylinder in *Gleichenia*, while that of *Platyzoma* is tubular. The sporangia arise simultaneously in the sorus, which is borne on the under surface of the ordinary pinna; in those species with large sporangia the latter form a single circle, in others sporangia may also arise from the central part of the receptacle. The annulus is horizontal and the dehiscence median. The prothalli, while resembling those of the *Polypodiaceae*, have points of similarity with those of the preceding groups.

Matoniaceae.—This contains the single genus *Matonia*, two species of which are known from the Eastern Tropics. They are of special interest, since they have been shown to be the surviving forms of a group species of which have been identified from Jurassic and Cretaceous rocks. The living species have a long rhizome, from the upper surface of which the large leaves arise; these are branched in a pedate manner, each branch being pinnate. The structure of the rhizome is complicated, a transverse section showing that the centre may be occupied by a solid stele, outside of which are two tubular steles. The sori are borne on the under surface of the pinnae, each consisting of a single series of large sporangia covered by a coriaceous indusium, which is attached to the central part of the receptacle. The sporangium, which corresponds on the whole to that of the *Gleicheniaceae*, has a somewhat oblique annulus; the dehiscence also is not truly median. The gametophyte is unknown.

Loxsomaceae.—The single genus *Loxsoma* has a tubular stele in its rhizome, which bears leaves resembling those of some *Davallias*. The elongated receptacle of the marginal sori is surrounded by a basal cup-shaped indusium. The sporangia, which arise in basipetal succession on the receptacle, dehisce by a median slit, though the annulus is somewhat oblique; they have resemblances to the *Gleicheniaceae*. When mature, the sporangia are raised above the margin of the indusium by the elongation of the receptacle, thus facilitating the dispersion of the spores. The gametophyte is unknown.

Hymenophyllaceae.—This group, which contains the two genera *Hymenophyllum* and *Trichomanes*, is characterized by the prevalent "filmy" texture of the leaves. Many of the species inhabit situations in which the air is constantly moist, especially in the tropics; some are terrestrial; others epiphytic on tree stems, or, in the case of the smaller species, some of which are very minute, on the leaves of other plants. A single solid central cylinder is found in the rhizome. The sori, which are marginal, have a long receptacle, bearing the sporangia in basipetal succession, and are surrounded by a cup-shaped indusium. The sporangia present a considerable range in size, the largest being found in species of *Hymenophyllum*, the smallest in *Trichomanes*. Each has an almost horizontal annulus resembling that of *Gleichenia*, but the dehiscence is lateral. The gametophyte in *Hymenophyllum* is flat and variously lobed; that of *Trichomanes* may be similar, but in other species is filamentous. The archegonia and antheridia present points of similarity to those of the *Gleicheniaceae*.

Cyatheaceae.—This order includes the majority of existing tree-ferns, as well as some of smaller size. The anatomy of the stem, with its ring of flattened steles, is figured in the article on FERNS. The sorus has a somewhat elongated receptacle, on which the sporangia arise basipetally; the indusium may be cup-shaped, bivalve, or wanting. The dehiscence of the sporangium is almost transverse, as in the *Polypodiaceae*, but the annulus is slightly oblique. The prothalli correspond to those of the next group.

Polypodiaceae.—This group, which contains the remaining Ferns, will doubtless require subdivision as our knowledge of the morphology of the genera classed in it becomes extended. The stem rarely has a tubular stele; for the most part two to many steles, arranged in a ring or in two concentric circles. In a number of genera, which there is reason to regard as relatively primitive, the sporangia show the same regular basipetal succession as in some of the preceding groups; in the great majority, however, the succession is not regular, but those of various ages are intermixed in the sorus. The sporangia dehisce by a transverse slit, the annulus being truly

vertical or, in some of the genera in which they are regularly arranged, very slightly oblique. The prothallus and sexual organs are of the type described in the article on FERNS; some of the more interesting modifications have been referred to above.

A consideration of the *Filicaceæ* as arranged above will show that the several suborders may in general terms be said to form a series between those in which the sorus consists of a single circle of bulky sporangia and those *Polypodiaceæ* in which the numerous small sporangia appear to be grouped without order in the sorus. When the survey is extended to the extinct Ferns of which the fructification is known, those from the more ancient rocks are found to group themselves with the existing suborders with large sporangia, such as the *Marattiaceæ*, *Gleicheniaceæ*, and *Schizæaceæ*; the *Polypodiaceæ*, on the other hand, do not appear until much later. The extinct forms cannot be dealt with in detail here; but it may be pointed out that their order of appearance affords a certain amount of direct evidence that the existing Ferns with a single circle of large sporangia in the sorus are relatively primitive. The series which can be constructed from a study of the sorus is in general supported by the anatomy of the sporophyte, and by the structure and sexual organs of the gametophyte. A more detailed investigation of all the characters of the Ferns will be needed before the course of evolution thus broadly indicated can be traced, but the results obtained by Bower afford a deeper insight into the general method of progression and the selective factors in the process. On the ground mainly of an examination of the sorus and sporangium, Bower has shown that the *Filicaceæ* may be divided into three groups—the *Simplices*, *Gradatæ*, and *Mixtæ*—in which the sporangia arise simultaneously, in basipetal succession, or irregularly in the sorus respectively. The first includes the *Marattiaceæ*, *Osmundaceæ*, *Schizæaceæ*, *Gleicheniaceæ*, and *Matoniaceæ*; the second the *Loxsomaceæ*, *Hymenophyllaceæ*, *Cyatheaceæ*, and the *Dennstædtineæ* (a group including species placed in the *Synopsis Filicum* in *Dicksonia* and *Davallia*); while the remaining *Polypodiaceæ* constitute the *Mixtæ*. The change from the one type of sorus to the other may have taken place in several different lines of descent, some of which have been traced. A consideration of the biology of the sorus gives an insight into the advantages obtained by the one type over the preceding, as regards protection, spore production, and the dispersal of the spores, and thus indicates the way in which natural selection may have acted. The differences in the form and mode of dehiscence of the sporangia (those of the *Simplices* having median dehiscence and a horizontal annulus, those of the *Gradatæ* a more or less oblique position of the annulus and of the plane of dehiscence, while in the *Mixtæ* the annulus is vertical and the dehiscence transverse) stand in relation to the position of the sporangia in the sorus relatively to one another. The application of the important criteria, which Bower has thus pointed out, to the construction of a strictly phylogenetic classification of the *Filicaceæ* cannot be made until the anatomy, the sexual generation, and the palæobotanical evidence have been further examined from this point of view. Though on this account and because, as Dr Bower himself points out, the subdivisions *Simplices*, *Gradatæ*, and *Mixtæ* do not correspond to definite phylogenetic groups, they have not been used in classifying the Ferns above, their importance as an advance towards a natural classification should be fully recognized. It may be added that in the large number of existing forms and the numerous fossil remains of those that have become extinct the *Filicaceæ* offer an opportunity such as is perhaps afforded by no other group for the study of the history of descent.

Hydropterideæ.—The uncertainty which exists as to the exact affinity of the two orders of *Pteridophyta* placed in this group must be associated with the more or less complete aquatic habit of the plants belonging to them. This general characteristic is expressed in the name *Hydropterideæ*, while that of *Rhizocarpæ*, under which they were described in the article FERNS, rests on an early misconception of their morphology. For a general account of the group the article named should be consulted. Since it was written, repeated detailed investigations have resulted in a very complete knowledge of the structure and development of the four genera of this group: space will not allow of a full account being given here, and for this some of the works cited below must be referred to. Mention must, however, be made of the anatomy and the reproductive structures of the sporophyte to indicate the difficulty of deciding the affinity of these orders. The latter are associated by the well-marked heterospory they exhibit; but such a character does not necessarily indicate a natural group, and there is some reason to believe that the nearest relations of the *Salviniaceæ* and *Marsileaceæ* are to be found at different points in the series of Homosporous Ferns. In the *Salviniaceæ*, which contain two genera of small floating plants, *Salvinia* and *Azolla*, the sporangia are associated in sori surrounded by an indusium springing from the base of the receptacle. The sori consist either of microsporangia or megasporangia, which are arranged, except when only one is present, in basipetal succession on the receptacle; this suggests that an affinity may be found with some of the groups placed in the *Gradatæ* by Bower. The complete absence of an annulus from the sporangia prevents the comparison from being carried farther; and the vascular system is so reduced, probably in relation to the aquatic habit, that the anatomy affords no safe guide. The same holds good to some extent for the *Marsileaceæ*; but here the presence of a tubular stele in the forms, with thicker rhizomes, affords an indication, at least, that their affinity is also with the *Gradatæ*. In structure and development the sporocarp is, however, essentially different from the indusiate sorus of the *Salviniaceæ*, and, though its position on the ventral surface of the leaf-stalk presents a difficulty, must probably be regarded as corresponding to a modified leaf-lobe. In the absence of direct evidence from Palæobotany, and bearing in mind the modifications associated with adaptation to an aquatic life in other plants, the recognition of any more definite affinity for these heterosporous Ferns appears to be inadvisable. Further evidence is necessary before they can be removed from such a position of convenience as is assigned to them here, and placed in relation to the series of *Filicaceæ*.

Phylogeny.

The several phyla of *Pteridophyta* having now been briefly described, their relationship to one another remains for consideration. The available evidence does not suffice to solve this question, although certain indications exist. In the earliest land vegetations of which we have any sufficient record specialized forms of *Equisetales*, *Lycopodiales*, *Sphenophyllales*, and *Filicales* existed, so that we are reduced to hypotheses founded on the careful comparison of the recent and extinct members of these groups. In this connexion it may be pointed out that the fuller study of the extinct forms has as yet been of most use in emphasizing the difficulty of the questions at issue. It has thus led to a condition of uncertainty as regards the relationship of the great groups of Vascular Cryptogams, in which, however, lies the hope of an ultimate approach to a satisfactory solution. The study of the *Sphenophyllales*, however, as has been pointed out above, appears to indicate that the *Equisetales* and *Lycopodiales* may be traced back to a common ancestry. As to the relationship of the *Filicales* to the other phyla, evidence from extinct plants appears to be wanting. If, as has been

suggested by Bower, the strobiloid types are relatively primitive, the large-leaved *Pteridophyta* must be supposed to have arisen early from such forms. The question cannot be discussed fully here, but enough has been said above to show that in the light of our present knowledge the main phyla of the Vascular Cryptogams cannot be placed in any serial relationship to one another.

It may even be regarded as an open question whether some of them may not have arisen independently and represent parallel lines of evolution from Bryophytic or Algal forms. This leads us to consider the question whether any indications exist as to the manner in which the *Pteridophyta* arose. It will be evident that no direct record of this evolution can be expected, and recourse must be had to hypotheses founded on the indirect evidence available. There appears to be no reason to doubt that the sexual generation is homologous with the thallus of a Liverwort, or of such an *Alga* as *Coleochæte*. It is with regard to the origin of the spore-bearing generation of the *Pteridophyta* that differences of opinion exist. This, though at first dependent on the prothallus, soon becomes independent. It may be regarded as derived from a wholly dependent sporogonium not unlike that of some of the simpler *Bryophyta;* the latter are assumed to have arisen from primitive Algal forms, in which, as the first step in the interpolation of the second generation in the life cycle, the fertilized ovum gave rise to a group of swarm-spores, each of which developed into a new sexual plant. On this view the origin of the sporophyte is looked for in the gradual development of sterile tissue in the generation arising from the fertilized ovum, and a consequent delay in spore-formation. Certain green *Algæ* (*e.g.*, *Œdogonium*, *Coleochæte*), the *Bryophyta*, and the simpler *Pteridophyta*, such as *Phylloglossum*, are regarded as illustrating the method of progression, though the existing forms may not constitute an actual series. For a discussion of this view, which regards the alternation of generations in Pteridophytes as antithetic and the two generations as not homologous with one another, reference may be made to the works of Celakovsky and Bower. Although the antithetic theory is supported by many facts regarding the life-history and structure of the group of plants under consideration, it must be remembered that it is at least possible that a stage in which the sporophyte was wholly dependent on the gametophyte may not have been passed through in their evolution. The spore-bearing generation may throughout its phylogenetic history have been independent at one part of its life, and have been derived by modification of individuals homologous with those of the sexual generation, not by the progressive sterilization of a structure the whole of which was originally devoted to asexual reproduction. A number of facts regarding the *Algæ*, and also those relating to such deviations from the normal life cycle as apogamy or apospory, may be regarded as lending support to this view, which, in contrast to the theory of antithetic alternation, has been called that of homologous alternation. Without entering farther into the discussion of these alternative theories, for which the literature of the subject must be consulted, it may be pointed out that on the latter view the strobiloid forms of *Pteridophyta* would not necessarily be regarded as primitive relatively to the large-leaved forms, and also that the early stages of the origin of the sporophyte in the two cases may have proceeded on different lines.

Another question of great interest, which can only be touched upon here and may fitly close the consideration of this division of the Vegetable Kingdom, concerns the evidence as to the derivation of higher groups from the *Pteridophyta*. The most important positive evidence on this point appears to indicate that the most ancient Gymnosperms were derived from the *Filicales* rather than from any other phylum of the Vascular Cryptogams. A number of extinct forms are known intermediate between the Ferns and the Cycads, and classed as *Cycadofilices*, some of which, when their reproduction is more fully known, may have to be classed with the *Filicales* rather than with the Gymnosperms. These forms will, however, be found discussed in the articles treating of extinct plants and the Gymnosperms, but their recognition will serve to emphasize, in conclusion, the important position the *Pteridophyta* hold with regard to the existing flora.

Public Health.—Few branches of law have expanded more rapidly than the law of public health. Premising that the Local Government Act, 1894, transferred to urban and rural district councils, elected by ballot by the parochial electors, the powers of the existing urban and rural sanitary authorities, and also conferred on such councils certain powers related to public health (*e.g.*, the execution of the Acts as to petroleum and infant life protection), we may commence with the Public Health Acts Amendment Act, 1890, and the Public Health Act, 1896. The first of these statutes confers enlarged powers on such local authorities as choose to adopt it—the right of adoption being general in the case of urban authorities, and in that of rural authorities limited to certain specified provisions unless it is extended by the Local Government Board. The adoption is effected by a resolution passed at a meeting of the local authority convened by special notice for the purpose, and a copy of the resolution is required to be sent to the Local Government Board, and—where certain parts of the Acts are adopted—to the Board of Trade and the Home Office. After some general provisions, the Act deals successively with (i.) danger or obstruction caused by telegraph, telephone, lighting, railway signalling, and other wires; (ii.) sewers, sanitary conveniences, and similar matters; and (iii.) music and dancing licences. A word may be said in regard to each of these sections in turn. (i.) Urban authorities are empowered to make by-laws for the prevention of danger or obstruction to the public from wires of the class indicated, and any apparatus connected with their erection. Provision may be made for the inspection of such wires, and offenders against by-laws are liable to penalties on conviction by a court of summary jurisdiction, subject to an appeal to quarter sessions; and the court may also order the removal of any wire or apparatus so placed as to constitute a contravention. The by-laws before taking effect must have been submitted to, and confirmed by, the Board of Trade. The Board of Trade may exempt from the operation of such by-laws for a maximum period of five years from their confirmation any wires, &c., already erected. But any danger arising from an exempted wire may be dealt with on application to a court of summary jurisdiction. None of the above provisions applies to wires belonging to the Postmaster-General, or undertakings under the Electric Lighting Acts, or is to interfere with the working of mines lying under or adjacent to any street along or across which wires have been stretched. (ii.) Injurious matters, chemical refuse, waste steam, &c.,

are not to be turned, or allowed to pass into drains; the local authority is enabled to make communications with, or repair drains at the owner's or occupier's expense, and also to make by-laws regulating the provision and maintenance of sanitary conveniences in manufactories and elsewhere; common courts and passages are to be kept clean; medical officers and inspectors of nuisances are empowered to seize, and justices to condemn all unsound "articles intended for the food of man" which are sold, or exposed or being prepared for sale within the district of any local authority, and the licence of the occupier of any slaughter-house who is convicted of the sale of any meat unfit for food may be revoked; hoardings are to be set up during the progress of buildings; cellars under streets are to be kept in good repair, and safe means of ingress to and egress from places of public resort, such as churches, chapels, or theatres, are to be provided. Similar provision is made for the safety of platforms on public occasions, and of whirligigs, swings, and shootings galleries. Urban authorities are enabled to provide refuges in streets, cabmen's shelters, and public clocks. (iii.) Places to be used for public dancing, music, &c., are to be licensed by the licensing authority of the district in which they are carried on. The licences are granted annually in October, except in Middlesex, where, under the Music and Dancing Licences (Middlesex) Act, 1894, they may be granted at any time.

The Public Health Act, 1896, abolishes the old system of quarantine, and empowers the Local Government Board to make regulations as to the landing of infected persons from ships. Elaborate provision has been made for the notification of infectious diseases by the Infectious Diseases (Notification) Acts, 1889 and 1899. The former statute was originally adoptive only, but it has now been extended by the latter to every district in England or Wales —in London notification has been compulsory since 1891. For the purposes of these Acts "infectious disease" means smallpox, cholera, diphtheria, membranous croup, erysipelas, scarlatina or scarlet fever, typhus, typhoid, enteric, relapsing, continued or puerperal fevers, as well as any other infectious disease which, by a resolution duly passed by the local authority, and sanctioned by the Local Government Board, is declared to be included within the definition. When any such disease occurs in any building used for human habitation, or in any ship, boat, tent, van, shed or similar structure (other than Crown buildings, or ships, vessels, or boats belonging to any foreign Government), the fact must be notified to the medical officer of health of the district. The duty of giving this notification is imposed, first on the head of the house to which the patient belongs, failing whom, on the nearest relative present, and on his default on the person in charge of, or in attendance on, the patient, and on his default on the occupier of the building. Any medical practitioner visiting the patient is also bound to give notice. Reference should also be made to the following statutes: the Infectious Disease (Prevention) Act, 1890, provides for the inspection of dairies, and the cleansing and disinfecting of premises, and under the Public Health (Ports) Act, 1896, the Local Government Board may by order assign to any port sanitary authority powers or duties arising under this statute. The Isolation Hospitals Act, 1893, enables county councils to promote the establishment of hospitals for the reception of patients suffering from infectious diseases; the Cleansing of Persons Act, 1897, enables local authorities to permit persons who apply to them, on the ground that they are infested with vermin, to have the gratuitous use of cleansing apparatus; and the Vaccination Act, 1898, profoundly modified the law as to vaccination.

Notification of infectious diseases.

In addition to these statutes, account has to be taken of a large body of legislation which relates indirectly to the law of public health, or at least comes well within its range of operation. It deals with a very great variety of subjects, and only a comparatively slight sketch of its results need be given here. The Factories and Workshops Act, 1895, extended the Factory Acts to laundries and docks, and enlarged the powers of courts of summary jurisdiction to provide for the safety of these establishments, especially as regards protection from fire. The Coal Mines Regulation Act, 1896, aims at the prevention of accidents due to inflammable gas and coal-dust in coal mines. The Merchant Shipping Act, 1894, enabled local authorities to make by-laws providing *inter alia* for the licensing, inspection, and sanitary condition of seamen's lodgings. The Rivers Pollution Prevention (Borders Councils) Act, 1898, enables joint committees of English and Scottish county councils of counties on both sides of the Border (viz., Northumberland and Cumberland in England, and Dumfries, Roxburgh, and Berwick in Scotland) to exercise the powers of the Rivers Pollution Prevention Act, 1876, in relation to any river or tributary which is partly in England and partly in Scotland—an expression including the Tweed. The Dangerous Performances Act, 1897, extends the earlier Act, 1879, which prohibited the employment in dangerous performances of children under 14 years of age, to boys under 16 and girls under 18, and also provides that, except where an accident causing actual bodily harm occurs, no prosecution may be instituted under either of the statutes without the consent in writing of the chief officer of police of the police area in which the offence is committed. The Infant Life Protection Act, 1897, which requires persons retaining for reward more than one infant under five, for nursing or maintenance for more than forty-eight hours, to notify the fact to the local authority, imposes upon local authorities the duty of instituting inquiries whether there are any persons residing within their districts who come within the Act, and empowers them to appoint male or female inspectors for the purpose of enforcing its provisions. Lastly, reference may be made to the Contagious Diseases (Animals) Act, 1894, which consolidated the law on this subject.

London.—Down to the year 1891 London was governed, in matters of public health, by a series of special statutes and by provisions in the general statutes, the scope of which is explained in the article on PUBLIC HEALTH in vol. xx. of this Encyclopædia. The law as to the metropolis was, however, consolidated, and is now regulated by the Public Health (London) Act, 1891. The authorities for the execution of the Act were, for the City of London, the Corporation, the vestries of the larger and the district boards of some of the smaller parishes, and certain boards of guardians. Under the Local Government Act, 1899, the powers of each existing vestry and district board are transferred to the council of the borough comprising the area within the jurisdiction of such vestry and district board; and the borough councils take over certain of the powers of the county council (*e.g.*, as to street obstruction and the registration of dairymen) and exercise concurrent jurisdiction with it in other matters. Provision is made for the appointment of medical officers of health and sanitary inspectors. The medical officer is for some purposes placed on the footing of a district poor-law medical officer, and he cannot be removed without the consent of the Local Government Board. In its structure and substance the Public Health (London) Act, 1891, which consists of 144 sections, closely resembles the general Acts. The principal matters with which it deals are: (i.) nuisances, general and

particular; (ii.) workshops, bakehouses, and dairies; (iii.) removal of refuse; (iv.) water-closets, &c.; (v.) food and water; (vi.) infectious diseases and epidemics; (vii.) hospitals and ambulances; (viii.) mortuaries; (ix.) lodging-tents and underground rooms; (x.) legal proceedings, appeals, and inquiries. On some of these subjects a few notes may be added. (i.) *Nuisances.*—It is the duty of every sanitary authority to inspect its district for nuisances. Certain nuisances, chiefly relating to the insanitary condition of premises, cisterns, closets, &c., may be abated summarily. The authority, on complaint by one of its officers or by any member of the public, if satisfied of the existence of the nuisance, serves a notice to abate it on the person in fault; and if this is not complied with, it may be enforced, under liability to a fine, by a nuisance order made by petty sessions. If the nuisance order includes a prohibition or closing order or requires structural alterations, an appeal lies to quarter sessions. The sanitary authority may also apply to the High Court for abatement of nuisances. Large powers of dealing with particular nuisances are given. (ii.) *Workshops, bakehouses, and dairies.*—The sanitary authority may order lime-washing and cleansing of workshops, other than bakehouses, to which some of the provisions of the Factory Acts are applied. The Local Government Board (in lieu of the Privy Council, 49 and 50 Vict. c. 32, s. 9) may make orders as to dairies. (iii.) *Removal of refuse.*—The sanitary authority is to clean streets and footways (which occupiers and owners are relieved of their duty of sweeping) and also remove house refuse, and any dustman demanding a fee or gratuity for removing dust is liable to a fine of 20s. The sanitary authority is also bound, if required, to remove trade refuse on payment of a reasonable sum. (v.) *Food and water.*—Provision is made for the inspection, seizure, and destruction of unsound food of any description intended for man. An occupied house without proper water supply is deemed a nuisance liable to be dealt with summarily, and if a dwelling-house is deemed unfit for human habitation, new houses are not to be occupied until after the water supply is certified; and a water company on cutting off a consumer's supply is to give notice to the sanitary authority. Petty sessions, on complaint by the sanitary authority, may close polluted wells whether public or private. (vi.) *Infectious diseases and epidemics.*—The provisions as to notification are practically identical with those under the general Acts. Elaborate provision is made for dealing with dangerous infectious diseases. Premises for disinfection, disinfectants, and carriages for removal are to be supplied. The medical officer of health or any medical man may order the disinfection of houses. The sanitary authority must house free of charge persons temporarily removed for disinfection, and pay for unnecessary damage and for articles destroyed. Penalties are imposed for throwing infectious rubbish into ash-pits and for letting an infectious house without proper disinfection. (vii.) *Hospitals and ambulances.*—Sanitary authorities may provide hospitals, recover their costs of maintaining non-infectious patients in them, and, with sanction, provide temporary supplies of medicine and medical assistance to the poorer inhabitants. The Metropolitan Asylums Board may provide landing-places, vessels, ambulances, &c. (viii.) *Mortuaries.*—Every sanitary authority is to provide a mortuary, and may, and if required by the county council must, provide a *post-mortem* room, not at a workhouse. Places for holding inquests and for preserving unidentified dead bodies are also to be provided. (ix.) *Lodging-tents and underground rooms.*—The sanitary authority is to make by-laws as to lodgings, and may make by-laws as to tents and vans, which, if in such a state as to be a nuisance, may be dealt with summarily. Underground rooms are not to be let or occupied as dwellings unless they satisfy certain stringent requirements prescribed by the Act as to height, drainage, ventilation, &c. Provision is made for the enforcement of this prohibition, and, in case of two convictions within three months, the court may order the room to be closed. (x.) *Legal proceedings, appeals, inquiries.*—A general power of entry on premises for the purposes of the Act is given to the sanitary authority. The county council has power to prosecute offenders on default by the sanitary authority; and the Local Government Board, on complaint by the county council, may also interfere. There is a general appeal under the Act from magistrates to quarter sessions, and from notices by or acts of the sanitary authority to the county council. Inquiries by the Local Government Board are to be held under the provisions of the Public Health Act, 1875.

Besides the Public Health (London) Act, 1891, it is necessary to note that the law of public health in London is also affected by a number of later statutes relating to the metropolis alone. Thus the Baths and Wash-houses Act, 1896, allows closed swimming-baths to be used gratuitously for music and dancing in London with the licence of the London County Council. The Canals Protection (London) Act, 1898, empowers the county council to require a canal company to protect dangerous places on its canal.

Scotland.—The various statutes relating to public health in Scotland are now consolidated and amended by the Public Health (Scotland) Act, 1897, which, together with the Infectious Diseases Notification Act, 1889 (*v. sup.*), and the Burgh Police (Scotland) Act, 1892, constitutes the statutory law of Scottish sanitary administration. The central authority is the Local Government Board for Scotland. The local authorities are—(i.) in burghs under the Burgh Police (Scotland) Act, 1892, the town council or burgh commissioners; (ii.) in other burghs, the town council or board of police; (iii.) in districts where the county is divided into districts, the district committee; (iv.) in counties not so divided, the county council. The substantive provisions are similar to those of the English Acts.

Ireland.—Most of the English Acts apply to Ireland with modifications and adaptations. See the following statutes: Infectious Diseases (Notification) Acts, 1889 and 1890; Cleansing of Persons Act, 1897. The collective title, "Public Health (Ireland) Acts, 1878 to 1896," was by the Short Titles Act, 1896 (59 and 60 Vict. c. 14) given to the consolidating Act of 1878, the Act of 1890, and the Act of 1896. See also the Local Government Act, 1898, §§ 32, 105, schedule 5. The most important of these statutes is the Public Health (Ireland) Act, 1896, 59 and 60 Vict. c. 54, which invested rural sanitary authorities with the powers and duties of urban authorities. The Public Health (Ireland) Act, 1900, gives power to the Local Government Board for Ireland to determine the area of charge in respect of certain special expenses.

United States.—It is within the police power of each state to legislate on such subjects as adulteration, contagious diseases, quarantine, vaccination.

(A. W. R.)

Publishing.—Under the description of Bookselling, the earlier volumes of the *Encyclopædia Britannica* (ninth ed., vol. iv. pp. 39, 40) dealt summarily with the early history of what is now known as publishing. It is, however, not quite correct in modern times to speak of publishing and bookselling as identical. The publisher now confines his energies entirely to the production and publication of books, while the bookseller retails them to the public. By this division a larger constituency is reached, as the bookseller's counter is considered the best medium through which a book can be seen and advertised.

A change of system.

Before dealing with the present system of publishing, it will be best, if only for comparison, to sketch briefly some of the methods of publishing which were in vogue during the later part of the 18th and the early part of the 19th century, before the severance of the seller from the producer of books. Formerly, by a system of association, the principal booksellers produced for themselves most of the books they sold, and in many cases they employed the authors to write them. Dr Johnson and Oliver Goldsmith, as well as many other well-known authors, were so engaged. By this system of co-operative publishing, prices were fixed, discounts regulated, and all trade questions easily adjusted. The cost of producing a book was borne by this circle of publisher-booksellers, who were called partners, and the books thus produced were usually of a popular character, such as dictionaries, natural histories, encyclopædias, and general educational literature. The interests in these works were frequently divided and subdivided into lots or shares, which, in the case of an expensive book, or of one for which a large circulation was anticipated, were sometimes very numerous and often formed a complex arithmetical problem. These divisions or shares in a book sometimes consisted of as many as 300 different lots. On the title-page of the first edition of Johnson's *Lives of the Poets* there were the names of thirty-six of these associated booksellers, and on the second edition of the same work, forty-two. The following extract from a trade catalogue sale which was held at the London Coffee House, Ludgate Hill, in 1805, will illustrate this curious custom:—

One 160th Johnson's *Dictionary* sold for £23	5	0
16 7/8 books in 3000 Pope's Works ,,	6	6	0
15 books in 1000 Sterne's Works ,,	11	0	0

And in a division by the partners of Cruden's *Concordance* the fractions of shares into which this once very popular book was divided were as follows:—

$$\frac{3}{52} \quad \frac{21\frac{1}{2}}{1500} \quad \frac{1}{18} \quad \frac{7}{60} \quad \frac{338\ \frac{527}{936}}{1000}$$

This partnership in the copyright of a book led to frequent meetings on the part of the proprietors to discuss new issues and divide profits. These transactions were usually accompanied by a dinner, which in later years developed into a trade usage, every publisher of importance during the last half of the 19th century giving at least one dinner in each year to his customers. This custom was continued until 1897, Messrs R. Bentley & Son being the last publishers to give a trade dinner, a year previous to their incorporation with Messrs Macmillan & Co. in 1898. Mr John Murray's trade sale dinner was discontinued in 1887, and Messrs Longman & Co.'s in 1872. On those occasions books were offered at a considerable reduction from the ordinary cost prices. The invitation to these dinners was always by a sale catalogue, which was sent out to "a select number of booksellers of London and Westminster," and which in its shape and character, for nearly 200 years, showed little change, the earliest known being dated 1704. They were always on thick woven folio paper, with broad margins for figures, with some such formulary as the following printed on the first page:—"Beginning at nine in the morning, when the whole company shall be entertained with a breakfast, and at noon with a good dinner and a glass of wine, and then proceed with the sale, to finish that evening."

From this early period down to the middle of the 19th century the stock sold at these sales consisted largely of miscellaneous books, besides those which the publisher-bookseller himself partly controlled. After that date the shares of most of these partnership books were either bought up by one partner or through the lapse of time became worthless, the old methods gradually died out, and the publisher, as we know him, became the sole producer of the works which the booksellers sold.

There were, however, during the first half of the 19th century several great publishing houses, some of whom still exist, who, with foresight and discretion, issued many of their publications on their own responsibility, notably the house of Longmans, who speculated large sums in the works of Wordsworth, Moore, Macaulay, and also in the issue of the *Edinburgh Review*. This was true also of John Murray, who paid immense sums to Lord Byron, Scott, Crabbe, Irving, Hallam, Southey, and to the writers in the *Quarterly Review*. The same business methods existed in the houses of Blackwood, Colburn, Constable, Rivingtons, A. & C. Black, and others, who displayed great knowledge of the requirements of that age, many of them making large fortunes.

This complete centralization of the publisher's responsibility developed many changes, some of them considerably influencing the relation of the author to the publisher as well as the position of the publisher to the bookseller. There also grew up conditions in these trades which eventually led to the formation of protection societies for the author, the publisher, and the bookseller.

The old-established publishers, being in many instances men of culture and education, gathered round them authors of position and renown, with whom they became on intimate terms. A personal relationship was thus fostered which frequently resulted in business suggestions beneficial to both author and publisher. This is further illustrated in the published lives of the Murrays, the Blackwoods, of Daniel Macmillan, and Adam Black, as well as in the biographies of authors themselves. The great commercial prosperity which was associated with this and a later period induced many men of enterprise and capital to enter the publishing trade, with the result that through the multiplicity of publishers a competition arose for the successful writer, which, although enriching the author, has occasionally severed many pleasant social relationships. There are, however, still many exceptions to this condition of affairs.

Publishers' readers.

The changes which have affected the publishing trade from time to time are well illustrated by the difference in the position of the publishers' readers—those men of letters who assist and advise the publisher in the literary side of his business. In the time of Dr Johnson, when the publisher was practically no more than a bookseller, and publishing mainly consisted in combinations of booksellers to share expenses, there was very little room for independence in the position of their literary advisers. Indeed, at that time the publisher's reader, so far as he existed, was practically the publisher's "hack," engaged in odds and ends of literary work at a very insufficient stipend, and subject at times to actual indignities at the hand of his employer. In some such position Johnson himself served Cave at St John's Gate, Clerkenwell; and most of the booksellers could claim the assistance of a ready man of this description, though rarely, of course, of equal distinction.

Gradually, however, as the business of publishing assumed a different complexion, there was a tendency for each bookseller to act for himself, and little literary cliques were gathered around the different houses, ready to advise and assist. In this way the *Quarterlies* sprang into existence, and rivalry became more direct and more lively between the different houses. Then each house sought to become the exclusive publisher to the best writers of the day, and the duties of the publisher's adviser became more extensive. He was often something of a go-between from publisher to author, and himself a writer of distinction and high reputation. Scott's relation to the Ballantynes and Gifford's to Murray are almost inseparable from many of the associations of the publisher's reader: they read manuscripts and advised upon proposals, consulted with writers, and represented the literary conscience and judgment of the firms, to whom they stood as friendly sponsors. But the development did not stop there. "The mob of gentlemen who write with ease" increased so rapidly in number and pertinacity that it soon became necessary for every house to keep in constant employ at least one, and often several advisers, who should read the manuscripts and report upon their quality. By the beginning of the 'thirties this custom was universal; and the reader was also expected to suggest schemes and help to carry them through. Charles Whitehead, for example, a Bohemian of the old school, was responsible to the firm he served for the suggestion that Charles Dickens should be asked to write *The Pickwick Papers* to accompany a series of projected illustrations by Seymour. In this way the position of "reader" often became a very responsible one, and gave many meritorious but undistinguished men of letters a chance of affording their first opportunity to writers who were soon to outstrip them alike in commercial value and in literary reputation. Thus it was Mr Smith Williams, the reader, who induced Mr George Smith (Smith, Elder & Co.) to publish *Jane Eyre*. Then, as the competition among publishers became more acute, and the business gave wider opportunities for taste and culture, the status of the "reader" naturally advanced *pari passu*. A man of judgment and executive skill was able to indicate to a promising writer faults which might easily be remedied and qualities which should be cultivated; courtesies of this kind made for business, and so there grew up a new rivalry between house and house, who vied with one another in securing the best advice available.

These were the golden days in the history of the publisher's reader, and they were perhaps at their zenith in the middle 'seventies. Then Mr John Morley, for example, advised Messrs Macmillan, and Mr George Meredith Messrs Chapman & Hall; and several of the most distinguished writers of our day bear testimony to the invaluable advice which they received from these gentlemen at the outset of their own careers, advice extending to a detailed examination of their manuscripts, and elaborate suggestions for their improvement and alteration. The recent increase, however, in the number of publishers, and the purely mercantile nature of certain developments in the business, seem not unlikely in the future to undermine the position of the "reader," and to render him once more a mere appanage of the office. This change of front is, no doubt, chiefly attributable to the growing tendency to neglect the old and intimate personal relations between publisher and author, and to entrust the whole of the business arrangements to a literary agent or middleman, who undertakes the entire conduct of a manuscript from the time it leaves the author's hand until the day of its publication, arranges the author's contract, and collects his dues. The result of this innovation, however effectually it may relieve the writer of business anxieties, has undoubtedly been to separate author from publisher, and very often to deprive the author of the advantage of the publisher's experience in the way of advice and direction. In this way the "reader" has lost the better part of his occupation. Instead of being a cultured expert, prompting the writer with suggestions, he tends to become a sharp man of business, acquainted with the "sales" of every successful author, and the sums which it is safe to adventure in advance of publication, and the young and inexperienced writer seems likely to find less and less literary assistance within the walls of a publishing house.

There are naturally several branches of publishing into which this rather illiberal competition cannot enter, and here the more humane functions of the literary adviser are still unimpaired. The fields of *belles lettres*, criticism, bibliography, scientific and (perhaps) educational literature are exempt from the present stress of the market, and it is here that we must look for the preservation of the calmer and more dignified spirit of business. Here the "reader" has still his place and his opportunity. But in the wider field of general publishing his position has almost certainly passed its meridian, and only a complete change in the nature of business methods can restore it to the privileges and satisfactions which it once enjoyed.

The literary agent.

Competition among publishers for the successful author assisted in the establishment about 1880 of the literary agent. The business of these literary agencies, of which there are about ten, is to dispose of an author's MS. to the highest purchaser, to arrange for the serial issue of the work, to negotiate and settle the American and foreign editions, to keep the author's accounts, and to act as the intermediary between him and the publisher, for which he charges a commission. Some publishers resent this interference, and will not consider a MS. coming through these sources; but the demand for the work of a popular writer is always great, and through the prices obtained by means of the literary agent an author is stimulated to give quantity rather than excellence of work, thereby frequently enriching himself at the expense of his reputation.

The Authors' Society.

Growing up about the same time and covering somewhat the same ground as the literary agent is the Society of Authors. This society, which owed its inception mainly to the initiative of Sir Walter Besant, was established in 1883, and from its commencement met with a considerable amount of support from the workers in literature. Lord Tennyson became its first president, and Lord Lytton, Matthew Arnold, Huxley, Tyndall, and Dr Martineau were among its 36 vice-presidents. The registered office of the society is 39 Old Queen Street, Storey's Gate, S.W. Its accredited organ, *The Author*, was established in May 1890, and has a circulation of over 2000 copies; the subscription to the society is £1, 1s. per annum, or 10 guineas for a life membership. In the first year of its existence it had only 68 paying members; it now has over 1300. The main principles of the society are: (1) the maintenance, definition, and defence of literary and musical property; (2) the consolidation and amendment of the law of domestic copyright; (3) the promotion of international copyright. The society has grown with its requirements, and now not only aims at defining and establishing the principles and methods of publishing, but examines agreements and advises authors as to the best publishers for their purpose. It looks through and carefully examines publishers' accounts and estimates for printing and production; it takes action on behalf of its members for the recovery of MSS.; and will for a small fee give a critical report upon the work of young

authors submitted to it. Although not antagonistic to the literary agent, it warns the author who is starting on his career not to enter into contracts or dispose of his MS. before consulting the society, as in his preliminary efforts the advice of the Authors' Society would be found useful. The great work of the society has been its continual insistence on the value of literary property and the right of the author to his share of profit. It has therefore laid down what it considers the heads under which the various methods of publishing should fall; these are as follows: (1) sale outright; (2) limited sale; (3) the half-profits system; (4) the royalty system; (5) publication by commission.

In discussing these proposals of the Authors' Society separately, it must be understood that variations may take place by agreement between author and publisher in any of the several departments, and the various arrangements are here explained rather than suggested as a system to be adopted for publishing. With regard to *sale outright* much might be urged, both for and against. It is not an infrequent occurrence for an author, who has probably put his most original work into his first book, to be unable to find a publisher. Cases might be mentioned where, after many unsuccessful attempts, an author has disposed of the copyright of his book for a nominal sum, and the work has afterwards turned out a surprising success. To the credit of the publishers, this success has generally been recognized by further payments, but legally the author has no further claim. It is therefore suggested that if an author considers his work to be one of merit, he should not dispose of his rights in the book. If, however, the author cannot afford to wait the verdict of the public, he is sometimes compelled to accept the best price offered for his MS. On the other hand, by sale outright the author dispenses with all future trouble, and the loss, if any, falls upon the publisher, who, in order to make his investment a satisfactory one, must do his best to make the book a success by reviews, advertisement, and through trade mediums. These advantages should be a considerable help to a young author.

The method of *limited sales* is not often adopted. It is an arrangement by which an author sells to a publisher the right of producing his book for a limited period for a stated sum, or sells a limited number of copies at an agreed price. Neither of these methods is considered desirable, and should never be undertaken without an agreement.

The *half-profits system* is less objectionable. According to this plan, the publisher produces the book at his own risk, and the net profits are divided in half or on an agreed ratio between author and publisher. Under this system the cost of production and advertising is met before any profit can accrue. This method should not, however, be undertaken unless the author knows well the integrity of the publisher with whom he is dealing, as under this arrangement it is possible for the publisher to take discounts in which the author does not share.

By far the most satisfactory system and the one most generally adopted is the *royalty system*, by which the publisher produces the book at his own cost and pays the author a royalty upon each copy sold. These royalties vary from 10 per cent. to 25 per cent., and in very exceptional cases to 30 per cent., according to the reputation of the author and the anticipated sale of the book. Sometimes by arrangement a royalty is paid upon all copies sold over and above a certain number, or after the cost of production has been covered, but none of these methods should be undertaken without an agreement legally drawn up and duly signed. Most of the leading novelists now publish on the royalty system, as by this they receive a larger return for their literary property. Frequently it is arranged that an author shall receive a large sum on depositing the MS. with the publisher, or on publication, on account of royalties, which in the case of a popular novelist will amount to thousands of pounds.

The method of *publishing on commission* is generally adopted when an author has opportunities for producing his book himself. By this method the work is issued at the expense and risk of the author, and the publisher or agent is paid by a commission on all copies sold, and also on the cost of production, should this be undertaken by the publisher or agent. Provided the book is a successful one, this method is, from a financial point of view, the most satisfactory to an author; for should he have time and opportunity to see the book through the press, he takes all the intermediate profits, and also the commission on production; but it has the objection that a publisher may not throw his energies into the sale of a commission book to the same extent that he would if it were issued upon the royalty system, or if he had himself bought the copyright.

In all these methods of publishing, care should be taken in drawing up agreements, and also, where possible, the copyright should remain in the possession of the author. The success of a book can frequently be traced not only to the effective way a publisher produces it, but also to the way he advertises it, and to the channels through which he causes his advertisements to pass; so that the selection of a publisher is an important matter. It is a fact that the name of a particular publisher on the title-page of a book is a guarantee that the book has been well considered before being issued; this has a great effect with the bookseller who stocks it, and also with the public who buy.

Undoubtedly one of the great factors in publishing, besides an exact knowledge of what to publish, is to bring before the book-buyer the particular character of book that he can use, without undue waste of either money or energy; and this can be done best by judicious advertising, and through the intelligent bookseller.

Remainders. To the author as well as the publisher one of the principal difficulties is the disposal of the books that do *not* sell, that is, to use the usual trade term, of "Remainders." With the consent of the author these are generally either sold by public auction or privately to a trader known as a remainder-buyer. Books so sold fetch a purely nominal sum, sometimes not amounting to the cost of the paper upon which they are printed. Some publishers prefer sending their unsaleable stock back to the paper mills to be repulped, rather than that they should be sold in this unsatisfactory manner. It has sometimes happened that a book sold out in this way has found its real place in a cheaper market, and a fresh and quite unexpected demand for the book has been created. In no case, however, should a book be remaindered until two years after its publication.

Although established after both the Authors' and Booksellers' Association, still, as the predominant partner in the trades coming between the author and the public, it would be right to treat here of the origin and work of the Publishers' Association of Great Britain and Ireland. This association was established in 1896, and had as its first president Mr C. J. Longman. It has a membership of about 70, consisting of all the principal London and provincial publishers. The objects of the association are to promote and protect by all lawful means the interests of the publishers of Great Britain and Ireland. The work undertaken and accomplished has been varied and useful, and in its results has affected the publishers themselves as well as the book trade generally. Amongst the most important questions discussed have been the stopping of colonial piracies, copyright, bibliography, trade terms, and publication agreements.

Publishers' agreement. The following are the principal clauses from a draft agreement between author and publisher drawn up by the association, which has received legal sanction and upon which agreements may be founded for publishing upon the royalty system:—

The publisher shall at his own risk and expense, and with due diligence, produce and publish the work, and use his best endeavours to sell the same.

The author guarantees to the publisher that the said work is in no way whatever a violation of any existing copyright, and that it contains nothing of a libellous or scandalous character, and that he will indemnify the publisher from all suits, claims, and proceedings, damages, and costs which may be made, taken, or incurred by or against him on the ground that the work is an infringement of copyright, or contains anything libellous or scandalous.

The publisher shall, during the legal term of copyright, have the exclusive right of producing and publishing the work in the English language throughout the world. The publisher shall have the entire control of the publication and sale and terms of sale of the book, and the author shall not, during the continuance of this agreement (without the consent of the publisher), publish any abridgment, translation, or dramatized version of the work.

The publisher agrees to pay the author the following royalties on the published price [these by arrangement].

No royalties shall be paid on any copies given away for review or other purposes.

The author agrees to revise the first and, if necessary, to edit and revise every subsequent edition of the work, and from time to time to supply any new matter that may be needful to keep the work up to date.

The author agrees that all costs of corrections and alterations in the proof sheets exceeding 25 per cent. of the cost of composition shall be deducted from the royalties payable to him.

In the event of the author neglecting to revise an edition after due notice shall have been given to him, or in the event of the author being unable to do so by reason of death or otherwise, the expense of revising and preparing each such future edition for press shall be borne by the author, and shall be deducted from the royalties payable to him.

During the continuance of this agreement the copyright of the work shall be vested in the author [or publisher], who may be registered as the proprietor thereof accordingly.

The publisher shall make up the account annually.

If the publisher shall at the end of three years from the date of publication, or at any time thereafter, give notice to the author that in his opinion the demand for the work has ceased, or if the publisher shall for six months after the work is out of print decline or, after due notice, neglect to publish a new edition, then and in either of such cases this agreement shall terminate; and on the determination of this agreement in the above or any other manner, the right to print and publish the work shall revert to the author, and the author, if not then registered, shall be entitled to be registered as the proprietor thereof, and to purchase from the publisher forthwith the plates or moulds and engravings (if any) produced specially for the work, at half cost of production, and whatever copies the publisher may have on hand at cost of production; and if the author does not within three months purchase and pay for the said plates or moulds, engravings, and copies, the publisher may at any time thereafter dispose of such plates or moulds, engravings, and copies, or melt the plates, paying to the author in lieu of royalties a percentage of the net proceeds of such sale.

If any difference shall arise between the author and the publisher touching the meaning of this agreement, or the rights or liabilities of the parties thereunder, the same shall be referred to the arbitration of two persons (one to be named by each party) or their umpire, in accordance with the provisions of the Arbitration Act, 1889.

Much business of an international character has also been undertaken by the association, especially in the important work of organizing the International Congresses of Publishers. The aim of these has been to promote and establish a true international friendship, so that if trade or other differences should arise in any country, they may be settled by the intervention of the publishers in the particular country; and also to extend the advantages of the Bern Convention by securing the adherence of those countries which have not yet joined (see COPYRIGHT). The first of these Congresses was held at Paris in 1896, the second at Brussels in 1897, the third at London in 1899, and the fourth at Leipzig in 1901. At all these Congresses questions were discussed, and in many cases settled, in a spirit which beneficially affected the trade of Great Britain and other countries, and which may go far to remove possible causes of future friction.

The net system.

One of the most important actions of the publishers, and one which has had a material bearing upon the bookselling trade of the United Kingdom, was the adoption and enforcement of what is known as the *Net System*, which means that no bookseller may give a discount to the public off the price at which a book is published when issued under this system. This arrangement was the subject of much discussion between authors, publishers, and booksellers, but eventually a *modus operandi* was arrived at, which was deemed satisfactory to the various interests in question, and on 1st January 1900 the system came into operation: publishers undertaking to discontinue supplying any bookseller who gave a discount off the selling price of net books, and the booksellers, through their association, signing an agreement to fall in with the publishers' proposals and to charge the published price, giving no discount. At the outset some of the discount booksellers took exception to the coercive policy thus introduced, but their opposition gradually died out, owing to the firm stand taken by the publishers; and although some objections are still raised against the system, it is in the main accepted as the best solution of the discount difficulty yet proposed. The publishers have at present refused to take action as to discounts in regard to books published in any other way than on the net system.

Discount.

Many previous attempts had been made to grapple with the discount difficulty. In July 1850 twelve hundred booksellers within 12 miles of the London General Post Office signed a stringent agreement not to sell below a certain price. This agreement was broken almost immediately. Another attempt was made in 1852; but at a meeting of distinguished men of letters resolutions were adopted declaring that the principles of the Booksellers' Association of that period were opposed to free trade, and were tyrannical and vexatious in their operation. The question was eventually referred to a commission, consisting of Lord Campbell, Dean Milman, and George Grote, which decided that the regulations were unreasonable and inexpedient, and contrary to the freedom which ought to prevail in commercial transactions. An attempt was also made in 1869 to impose restrictions upon the retail bookseller; but these also failed, mainly through the want of decided action on the part of the publishers. Later success was undoubtedly due to the unity of purpose which animated all parties, and was made possible through the existence of both a publishers' and booksellers' association, the members of which worked in harmony and towards a definite and settled end.

The 6s. novel.

Besides the discount question, there have been many disturbing elements in the publishing and bookselling trade. Perhaps no greater change ever took place than that which was brought about by the Education Act of 1870, which caused a revolution in educational literature, rendering most of the then existing school-books practically useless, new educational methods taking the place of the old-fashioned system of questions and answers. Another change was brought about by the abolition of the three-volume novel. It had always been the custom to issue works of fiction in several volumes. Richardson's *Clarissa Harlowe* was in 8 volumes, Fielding's *Tom Jones* in 6 volumes, and Sterne's *Tristram Shandy* in 9 volumes; but during nearly the whole of the 19th century, until 1897, three volumes were considered the regulation number for all novels. In 1894 Mudie's and Smith's circulating libraries sent to the publishers a circular suggesting drastic changes in the prices of this mode of issue, which had the effect of gradually reducing the number of novels in this form; and in the last year of their existence, 1897, only four novels were thus published. Up to this time the 6s. volume was reserved for the cheap edition of a work first published in three volumes, but the abolition of the latter opened the flood-gates for the publication of original fiction in one-volume form. The result has been a yearly growth in this department of literature, which now forms the principal stock of the general bookseller. To the popular novelist this change has been beneficial, as he at once appeals to the large majority of readers before the critics have had time to express their opinion, in one sense or another, which was hardly the case in the days of the three-volume novel. As illustrating the large demand created by this form of issue, it may be mentioned that of Miss Corelli's *The Master Christian*, published in 1900, nearly 260,000 copies have been sold; and of Mr Hall Caine's *The Eternal City*, published in September 1901, over 120,000 copies were disposed of in six months in Great Britain alone. Other examples

of large sales might easily be cited. By this one-volume form of issuing novels the colonial bookselling trade has been greatly benefited, as it is now usual to publish simultaneously with the English editions another edition entirely for sale in India and the Colonies. This trade is a very increasing one, and is considered an important factor in the sale of a book.

Cheap books. The increase in the publication of very cheap editions has been a feature of recent years. Enormous numbers of low-priced (even sixpenny) editions of standard works have been issued, and this is notably the case with cheap reprints of books of which the copyright has just expired. New novels of good standing have also been first published in a sixpenny edition. Akin to this is the practice of publishing novels serially in the cheap monthly magazines, such as those which Messrs Harmsworth, Newnes, and Pearson have popularized.

The number of books published in the United Kingdom somewhat declined between 1897 and 1902, the South African War and the death of Queen Victoria naturally affecting the book-market. In 1897 there were issued 6244 new books; in 1898, 6008; in 1899, 5971; in 1900, 5760; and in 1901, 4955. About 1500 in each year were fiction.

Distributing. Coming between the publisher and the retail bookseller is the important distributing agency of the *wholesale bookseller*. It is to him that the retailer looks for his miscellaneous supplies, as it is simply impossible for him to stock one-half of the books published. In Paternoster Row, which has for over a hundred years been the centre of this industry, may be seen the collectors from the shops of the retail booksellers, busily engaged in obtaining the books ordered by the book-buying public. It is also through these agencies that the country bookseller obtains his miscellaneous supplies. At the leading house in this department of bookselling almost any book can be found, or information obtained concerning it. At one of these establishments over 1,000,000 books are constantly kept in stock. It is here that the publisher calls first on showing or "subscribing" a new book, a critical process, for by the number thus subscribed the fate of a book is sometimes determined.

What may be termed the third partner in publishing and its ramification is the *retail bookseller;* and to protect his interests there was established in 1890 a London Booksellers' Society, which had for its object the restriction of discounts to 25 per cent., and also to arrange prices generally and control all details connected with the trade. The society a few years afterwards widened its field of operation so as to include the whole of the United Kingdom, and its designation then became "The Associated Booksellers of Great Britain and Ireland." This association, with the aid of the publishers, established the net system before mentioned, and by unity of action aims at stopping further underselling and the giving of ruinous discounts. Mr H. W. Keay is the president of the association, and the registered offices are 1 Bathurst Street, London, W.

The United States. From the beginning of the 20th century there has been a large influx into England of American literature, especially fiction. Not only has there been a growing appreciation of many American writers, but the attractive "get-up" of American books has made its influence felt upon the British market. Some of the American methods of distribution have also been attempted in Great Britain, but with only partial success. The most successful effort has been the sale of important expensive works through the medium of newspapers. Canvassing, which is a common method of distributing books in the United States, meets with little support in the United Kingdom, although about the middle of the 19th century a large trade was done throughout England and Scotland by canvassers, who sold in numbers and parts such works as Family Bibles, Daily Devotions, Lives of Christ, and Foxe's *Book of Martyrs*. It is, however, an acknowledged fact among publishers that there is still a large British public not reached through the ordinary channels of trade, and how this book-buying public can be touched is a question which is continually exercising the minds of the enterprising producer. The methods of publishing in America are similar to those adopted in Great Britain, but the discount to the booksellers is generally given *pro ratâ* according to the number purchased. It is, however, in respect of the means of distribution that the systems of the two countries differ most. In America the general stores to a considerable extent take the place of the English bookseller, and by their energy and extensive advertising a wider public is served. In the distribution of fiction the American plan of "booming" a book by copious advertising, although expensive, is often the means of inducing a large sale, and of bringing an author's name before the public, but it does not always establish a permanent reputation for him. In 1901 the net system, as adopted in Great Britain, was partially introduced into America.

The Continent. The Continental methods of publishing and distribution, especially in Germany, differ, in many respects very materially, from those of Great Britain. In even the smallest German towns there is a bookseller who receives on sale, immediately upon publication, a supply of such new books as he or the publisher may think suitable to his class of book-buyers. The bookseller submits these books to his customers, and by this method most books issued are at once placed at the disposal of any buyer interested in the particular subject. The large sums spent in other countries upon advertisement are thus saved. At the book fairs held in Leipzig at Easter and Michaelmas the accounts for books sent on sale are made up and paid. In France all books have to be licensed before publication, but the methods of publication differ little from those of other Continental countries.

British Publishing Houses.

The following firms, whose names are well known from the books they published, have ceased to exist:—

Bentley, R., & Son, founded by Richard Bentley in 1832. He started business with H. Colburn in 1829. In 1837 he commenced the issue of *Bentley's Miscellany*, in which Dickens's *Oliver Twist* and Ainsworth's *Guy Fawkes*, illustrated by G. Cruikshank, appeared. At his establishment in New Burlington Street, Richard Bentley and his son George gathered round them a famous band of men of letters; among them was the Rev. R. H. Barham, the celebrated author of *The Ingoldsby Legends*, which was first published in 1840. This firm also published the "Library of Standard Novels" and the "Favourite Novel Library." In the latter Mrs Henry Wood's *East Lynne* appeared. In 1866 the firm took over the publication of *Temple Bar*, founded by G. A. Sala and Edmund Yates; *Bentley's Miscellany* was afterwards incorporated with this magazine. Mr Richard Bentley was the last member of this firm, and he, with his father, Mr George Bentley (1828–95), worthily maintained its historical reputation until its incorporation by Messrs Macmillan & Co. in 1898.

Bohn.—Henry George Bohn, born of German parents in London in 1796, was a man of great literary and business activity. His father was a bookseller, and young Bohn in 1831 started as a dealer in rare books, besides buying up the surplus stock of publishers and selling them at a cheap rate to the retail booksellers. In 1841 he issued his celebrated *Guinea Catalogue*, a monumental work containing 23,208 different items. Bohn was also noted for his book auction sales; one held in 1848 lasted four days, the catalogue comprising twenty folio pages. Printed on this catalogue was the following information: "Dinner at 2 o'clock, dessert at 4, tea at 5, and supper at 10." The name of Bohn is principally remembered by the important "libraries" which he inaugurated; these were commenced in 1846, and comprised such subjects as history, science, classics, theology, archæology, &c., consisting in all of 766 volumes. The libraries were bought in 1864 by Messrs G. Bell & Sons. Bohn died in 1884.

Colburn.—Henry Colburn obtained his earliest experience of bookselling at the establishment of W. Earle, Albemarle Street, and afterwards as an assistant at Mr Morgan's Library, Conduit Street, of which in 1816 he became proprietor. He afterwards removed to New Burlington Street, where he established himself as a publisher, resigning the Conduit Street Library to Messrs Saunders & Otley. In 1814 he originated the *New Monthly Magazine*, of which at various times Thomas Campbell, Bulwer

Lytton, Theodore Hook, and Harrison Ainsworth were editors. Colburn published in 1818 *Evelyn's Diary*, and in 1825 the *Diary of Pepys*, edited by Lord Braybrooke, paying £2200 for the copyright. He also issued Disraeli's first novel, *Vivian Grey*, and a large number of other works by Theodore Hook, G. P. R. James, Marryat, and Bulwer Lytton. In 1830 Mr R. Bentley was taken into partnership; and in 1832 Colburn retired, but set up again soon afterwards independently in Great Marlborough Street; his business was taken over in 1841 by Messrs Hurst & Blackett. Henry Colburn died on 16th August 1855, leaving property to the value of £35,000.

Constable, Archibald, was born on the 24th of February 1776 at Carnbee, in Fifeshire. In 1788 he was apprenticed to Peter Hill, bookseller, of Edinburgh, but started in business for himself in November 1795 as a dealer in rare and curious books. the *Scots Magazine* was acquired by him in 1801, and Leyden, the poet, antiquarian, and Orientalist (d. 1811), became its editor. He introduced Constable to literary circles. In 1802 Constable commenced the *Farmers' Magazine*, and in the same year the *Edinburgh Review* burst upon an astonished world. The first number was issued in November 1802, under the nominal editorship of Sydney Smith; Lord Jeffrey was, however, the guiding spirit of the review, having as his associates Lord Brougham, Sir Walter Scott, Hallam, Playfair, and afterwards that brilliant essayist Lord Macaulay. Constable was also publisher of the *Encyclopædia Britannica*, then in its sixth edition, which passed in 1827 into the hands of Adam Black on Constable's failure. In 1804 A. G. Hunter joined Constable as partner, bringing considerable capital into the firm. In 1805, jointly with Longman & Co., Constable published Scott's *Lay of the Last Minstrel*, the demand for which exceeded anything previously known in the annals of British poetry; he also published, subsequently, *Marmion*. In 1808 a split took place between Constable and Sir Walter Scott, the latter transferring his business to the firm of Ballantyne & Co. In 1811, however, a reconciliation took place between Constable and Scott. Constable again became Scott's publisher; but the Ballantynes maintained their printing establishment, in which Scott was largely interested. In 1814 Constable purchased for £700 the copyright of *Waverley*. This was issued anonymously; but in a short time 12,000 copies were disposed of, Scott's other works following in quick succession. Through over-speculation, complications in Constable's business arose, and in 1826 a crash came. Constable's London agents stopped payment, and he failed for half a million of money, while Ballantyne also went bankrupt for £90,000. Constable began business afresh, but died on the 21st July 1827. After Constable's bankruptcy, Robert Cadell (who had been his partner), in conjunction with Sir Walter Scott, bought from the various publishers in whose hands they were all the novels which had been issued up to that time, and began the issue of the famous forty-eight volume edition, which was published in monthly volumes between 1829 and 1833. It was annotated by the author, who called it his Magnum Opus. The result of its publication was that the debt on Abbotsford was redeemed, and that Cadell bought the estate of Ratho, near Edinburgh, which he owned till his death in 1847. From Cadell's executors the entire copyrights of Scott's works were acquired by Adam and Charles Black in 1851.

Moxon.—Edward Moxon, poet and publisher, published in 1826 his first volume, entitled *The Prospect, and other Poems*, which was received with much favour as containing the germ of better things. In 1830 Moxon was started by Samuel Rogers as a publisher at 34 New Bond Street. The first volume he issued was Charles Lamb's *Album Verses*. In the following year he took over the publication of the *Englishman's Magazine*, which was contributed to by Charles Lamb (whose adopted daughter Moxon afterwards married), Arthur H. Hallam, and Alfred Tennyson. Removing to Dover Street, Piccadilly, Moxon published an illustrated edition of Rogers's *Italy*, £10,000 being spent upon the illustrations. In 1839 he issued the first complete edition of Shelley's poems. Some passages in *Queen Mab* were the cause of a charge of blasphemy being made against Moxon in 1841. The case was tried before Lord Denman. Serjeant Talfourd defended Moxon, but the jury returned a verdict of "Guilty," and the offensive passages were for a time eliminated. In 1840 Browning's *Sordello* was published; and in succeeding years works by Lord Houghton, Tom Hood, Barry Cornwall, Lord Lytton, Browning, and Tennyson appeared. Edward Moxon died on the 3rd of June 1858, his business being continued by Mr J. B. Payne and Mr Arthur Moxon, who in 1865 published Swinburne's *Atalanta in Calydon*; but in 1871 it was taken over by Messrs Ward, Lock & Tyler.

Knight, Charles, born at Windsor on 15th March 1791, was apprenticed to his father, a bookseller in the royal borough. Upon the completion of his indentures he practised journalism and interested himself in several newspaper speculations. He, W. & R. Chambers, and John Cassell were the forerunners of "literature for the people." In 1832, in conjunction with some Eton friends, he started *Knight's Quarterly Magazine*, to which Praed, Derwent Coleridge, and Macaulay contributed, many of the last-named's early poems appearing in its pages. In 1828 he started the *British Almanac* and the *Companion to the Almanac*, and also the "Library of Entertaining Knowledge." In 1832 there appeared the celebrated *Penny Magazine*, which reached a sale of 200,000 in weekly and monthly parts. This was followed by the *Penny Encyclopædia*, which was also a great success. Knight was the publisher of the works issued under the direction of the Society for the Diffusion of Useful Knowledge, with which Lord Brougham, Lord John Russell, and William Tooke were associated. The *Illustrated Bible*, edited by the Rev. Dr Kitto, the *National Encyclopædia*, *The Land We Live In*, *Popular History of England*, *English Encyclopædia*, and *Half-Hours with the Best Authors* were among the many works instituted and carried through by this earnest worker in popularizing good literature. He died at Addlestone, Surrey, 9th March 1873.

Of existing publishing houses, some date back into the early part of the 18th century. Their long and honourable record as leaders in the publishing world is inseparable from that of the literature of their time.

Murray, John.—The founder of this firm was John M'Murray, born at Edinburgh in 1745. In 1762 he was a lieutenant in the navy, but retired in 1768, and was soon engaged in the active business life of London. In 1766 he took over the old-established business of W. Sandby, Fleet Street; and after this period M'Murray found it convenient to drop the Scottish prefix, and called himself plain John Murray (1). In 1780 he issued the *London Mercury*, a volume of annual intelligence; and in 1783 he started the *English Review*. Among his earlier publications were Mitford's *Greece*, Langhorne's *Plutarch's Lives*, and, in 1791, D'Israeli's *Curiosities of Literature*. He died on the 6th November 1793, bequeathing to his only son his copyrights and business. John Murray (2), born in 1778, was only fifteen years of age when his father died. After a year or two, during which the widow nominally managed the business, Mr Highley was admitted a partner, and the firm became "Murray & Highley," the latter to conduct the business until young Murray came of age. In 1803 the partnership was dissolved, Highley taking all the medical publications. Afterwards, in 1812, Murray migrated to Albemarle Street, where, with uncommon gifts and a speculative spirit, he earned for himself the name, given to him by Lord Byron, of "The Anak of Publishers." In 1806 Murray married Miss Elliot, of Edinburgh, shortly afterwards publishing Mrs Rundell's *Domestic Cookery Book*, and in 1807 he took a share with Constable in publishing *Marmion*. Thus began a connexion with Sir Walter Scott, who, through differences arising on political questions with the writers in the *Edinburgh Review*, assisted Murray in launching a Tory periodical, the *Quarterly Review*, with Gifford as its editor, the first number being issued on 1st of February 1809; among the contributors being Scott, Canning, Southey, Barrow, and Hookham Frere. The *Quarterly* at once brought Murray into prominence with the Conservative leaders as well as with literary men. Murray was, jointly with Constable, the publisher of some of Scott's early poems and novels, but, greatly to his distress, he was compelled to break this association on account of the methods which, as he foresaw, ultimately led to disaster. In the spring of 1812 *Childe Harold* was published. This was brought to Murray by Dallas, to whom Byron had presented it, Murray paying £600 for the copyright. In the same year he bought the business and stock-in-trade of Mr Miller, 50 Albemarle Street, and transferred himself there. Literary London flocked to his house, and John Murray became the centre of the publishing world. In his drawing-room, at four o'clock daily, was collected together most of the talent, literature, and art of that time. It was in this room in 1824, after the death of Lord Byron, that the MS. of his autobiography, which he had given to Moore, was destroyed, it being considered by Gifford to be unfit for publication. A lifelong friendship existed between Lord Byron and his publisher, he having paid him nearly £20,000 for his various poems. Murray paid Thomas Moore £4200 for writing the life of Byron, to Crabbe £3000 for his *Tales of the Hall*, all his transactions being of the most generous character. In 1824, however, he lost £27,000 on the failure of his shortlived Conservative daily paper, the *Representative*. Murray was as celebrated for his books of travel as for *belles lettres*. He died on the 29th June 1843, leaving also an only son. John Murray (3), born in 1808, inherited much of his father's business tact and judgment. In early life he took especial pleasure in foreign travel; the famous handbooks for travellers were issued under his personal editorship, some of them being written by himself. In the first year of his accession he issued the "Home and Colonial Library," and in his selection of authors he successfully maintained the reputation of the old firm. One of his most successful books was Campbell's *Lives of the Chancellors*. He also issued books by Hallam, W. E. Gladstone, Lyell, Layard, Dean Stanley, Murchison, Darwin, Livingstone, and Samuel Smiles. He died 2nd April 1892, and was succeeded by

his son. John Murray (4) was born in London in 1851, was the second president of the Publishers' Association, and is an active worker in everything connected with the publishing and bookselling trade. He is associated in his business with his brother A. H. Hallam Murray.

LONGMANS, GREEN & Co.—This firm dates back farther than any other English publishing house. Its founder, Thomas Longman (1), born in 1699, was the son of Ezekiel Longman, described as a gentleman of Bristol, who died in the year 1708. Thomas was apprenticed in June 1716 to John Osborne, bookseller, of Lombard Street, London. At the expiration of his apprenticeship he married Osborne's daughter, and in August 1724 purchased the stock and household goods of William Taylor (the first publisher of *Robinson Crusoe*) for the sum of £2282, 9s. 6d. Taylor's two shops were known as the Black Swan and the Ship, and occupied the same ground in Paternoster Row upon which this famous publishing house now stands. Osborne, who afterwards entered into a partnership with his son-in-law, issued upon the share system, in conjunction with other booksellers, various educational books, and also Ephraim Chambers's *Cyclopœdia*. In 1754, having no son, Thomas Longman took his nephew, who was born in 1731, into partnership, the title of this firm becoming T. & T. Longman. Upon the death of his uncle in 1755, Thomas Longman (2) became the proprietor of all the partnership stock. He maintained the old traditions of the firm, and greatly extended his colonial trade. He married Miss Harris, and by her had three sons. Of these, Thomas Norton Longman (3), born in 1771, followed in 1797 his father in his publishing business. In 1794 Owen Rees became a partner in the firm, and Thomas Brown, who was for many years after 1811 a partner, entered the house as an apprentice. Mr Brown died in 1869 at the age of 92. In 1799 Longman purchased the copyright of Lindley Murray's *English Grammar*, which had an annual sale of about 50,000 copies; he also purchased about 1800 the copyright, from Joseph Cottle, of Bristol, of Southey's *Joan of Arc* and Wordsworth's *Lyrical Ballads*. He also published the works of Wordsworth, Coleridge, Southey, and Scott, and acted as London agent for the *Edinburgh Review*, which was started in 1802. From this period the firm greatly enlarged its business, issuing many works of an important character. In 1804 Mr Hurst and Mr Orme became partners; and in 1824 the title of the firm was changed to Longman, Hurst, Rees, Orme, Brown & Green. In 1814 arrangements were made with Thomas Moore for the publication of *Lalla Rookh*, for which he received £3000; and when the house of Constable, Edinburgh, fell in 1826, Longmans became the proprietors of the *Edinburgh Review*, while the advent of Thomas Babington Macaulay powerfully contributed to the fortune and reputation of the firm. They also issued in 1829 Lardner's *Cabinet Encyclopœdia*, which was contributed to by many of the most conspicuous workers in literature of the day; and in 1832 M'Culloch's *Commercial Dictionary*. Thomas Norton Longman (3) died on 29th August 1842, leaving his two sons, Thomas (4) and William Longman, in control of the gigantic business in Paternoster Row. Their first success was the publication of Macaulay's *Lays of Ancient Rome*, which was followed in 1849 by the issue of the first two volumes of his *History of England*, which in a few years realized a sale of 40,000 copies; the subsequent volumes reaped a still greater success; and a cheque for £20,000, on account of profits, given to Lord Macaulay is a record in payment for authorship. The two brothers were well known for their literary talent; Mr Thomas Longman edited a beautifully illustrated edition of the New Testament, and Mr William Longman was the author of several important books, among them being a *History of the Three Cathedrals dedicated to St Paul*, in which he took a great interest, and a work on the *History of the Life and Times of Edward III.* In 1863 the firm took over the business of Mr J. W. Parker, and with it *Fraser's Magazine*, and the publication of the works of John Stuart Mill and the historian J. A. Froude; while in 1890 they incorporated with their own all the publications of the old firm of Rivingtons, established in 1711, and with it the important works formerly issued by Hatchards, Piccadilly, whose publishing business had previously been bought by Rivingtons. The head of the present firm is Mr Thomas (5) Norton Longman, his brother Mr G. H. Longman, sons of Mr Thomas Longman; Mr C. J. Longman and Mr H. H. Longman, sons of Mr William; and Mr W. E. Green, being also members of the firm.

BLACK, ADAM & CHARLES.—The founder of this firm, Adam Black, was born in Edinburgh on 20th February 1784; he was the son of a builder of that town. After serving his apprenticeship to the bookselling trade, and a few years in London with Lackington, Allen & Co., he began business at 57 South Bridge, Edinburgh, in 1807. In 1826, at the time of Constable's (*q.v.*) failure, he was recognized as one of the principal booksellers in Edinburgh; he was joined in business a few years later by his nephew Charles. The two most important events connected with the firm were the publication of the 7th edition of the *Encyclopædia Britannica* and the purchase of the stock and copyright of the Waverley Novels. The original proprietors of the *Encyclopædia* were Andrew Bell and Colin Macfarquhar; in 1827 the copyright passed into the hands of Adam Black and a few friends, the 7th edition being published by him under the editorship of Professor Macvey Napier; its issue was commenced in monthly parts in March 1830, and finished in 1842. It was in twenty-one quarto volumes, and cost in production £108,766, the number sold being 4500 copies. An 8th and 9th edition were published by Messrs Black. In 1851 A. & C. Black bought the copyright of the Waverley Novels, at a cost of £27,000; and in 1861 they became the proprietors of De Quincey's works.

Adam Black was for some years M.P. for Edinburgh; he retired from business in 1865, and died on 24th January 1874. He was succeeded by his sons, who, finding that London would be more central for publishing, relinquished in 1895 their establishment at Edinburgh, and removed to 4, 5, and 6 Soho Square, London.

MACMILLAN & Co. LIMITED.—The founders of this firm were Daniel and Alexander Macmillan. The former was born in the Isle of Arran in 1813, while his younger brother was born at Irvine on 3rd October 1818. Coming to London, they entered the house of Seeleys in 1839; but Alexander in 1843 commenced business in Aldersgate Street, and in the same year the two brothers purchased the business of Newby, in Cambridge. In 1845 they became the proprietors of the more important business of Stevenson, in Cambridge, when Mr Barclay became a partner, the firm being styled Macmillan, Barclay & Macmillan. In 1850 Barclay's name disappeared from the title-pages of their publications, and the firm became settled in Cambridge. Mr Daniel Macmillan died in 1857, and in the same year an impetus was given to their business by the publication of Kingsley's *Two Years Ago*. A branch office was opened in 1858 at Henrietta Street, London, which led to a large extension of their trade. These premises were surrendered for larger ones in Bedford Street, and in 1897 their magnificent premises in St Martin's Street were opened. Mr Alexander Macmillan died in January 1896. By his great energy and literary associations, and with the aid of his partners, there had been built up in little over half a century one of the most important publishing houses in the world. Besides the issue of many important series of educational and scientific works, they published the works of Kingsley, Huxley, Maurice, Tennyson, Lightfoot, Westcott, J. R. Green, Lord Roberts, Lewis Carroll, with many other authors whose names are well known in literature. In 1898 they took over the old-established publishing house of R. Bentley & Son, and with it the popular works of Mrs Henry Wood, Miss Rhoda Broughton, *The Ingoldsby Legends*, and also *Temple Bar* and *The Argosy*. In 1893 the firm was converted into a limited liability company, with Mr Frederick Macmillan as chairman and Mr G. Macmillan, Mr G. L. Craik, and Mr Maurice Macmillan as directors. There is probably no English house which has such a large connexion in America as Macmillans. Although distinct in its trading, the Macmillan Company of New York has in Mr F. Macmillan one of its most important and experienced members.

RIVINGTON & Co.—Charles Rivington, the originator of this firm in 1711, was a Derbyshire man, who took over the business of Richard Chiswell, and at the sign of the Bible and the Crown carried on a business almost entirely connected with theological and educational literature. Charles Rivington was born at Chesterfield, and at an early age evinced a taste for religious books. He came to London, and was apprenticed to a Mr Matthews; and in 1718, in conjunction with other firms, he published Mason's *Vindication of the Church of England*. He also published one of Whitfield's earliest works, and brought out an edition of the *Imitation of Christ*. In 1736 he became one of the company of booksellers who called themselves the "New Conger." In 1741 he published the first volume of Richardson's *Pamela*, which went through five editions in its first year of publication. Charles Rivington died on 22nd February 1742, and was succeeded by his two sons, John and James. The latter turned to other pursuits, but John pursued his father's policy, and was known as the great Church of England publisher of the day. In 1760 he was appointed publisher to the Society for Promoting Christian Knowledge, retaining the agency for over seventy years. Having admitted his sons Francis and Charles into partnership, they commenced the issue of a standard edition of the works of Shakespeare, Milton, Locke, and other British classics; also Cruden's *Concordance*. John Rivington died on the 16th January 1792. Francis and Charles started in January 1793 the *British Critic*, in two-shilling numbers, which attained a circulation of over 3000 copies. In 1810 John, the eldest son of Francis, was admitted a partner; and in 1819 they took a lease of 3 Waterloo Place, where they remained until the business was sold, in 1890, to Messrs Longmans & Co. In 1827 George and Francis, brothers of John, joined the firm; and by the publication (1833) of *Tracts for the Times*, to which Newman, Pusey, and Keble contributed, the house of Rivingtons was strengthened in its position as High Church publishers. John Rivington died 21st November 1841, his son being admitted a partner in 1836. George Rivington also died in 1842; and in 1859 Francis Rivington retired, leaving the business in the hands of John Rivington and Francis Hansard Rivington.

As before stated, in 1890 the business and the right to trade were bought by Longmans & Co. A business of the same character was, however, carried on from 1889 to 1893 by Mr Septimus Rivington and Mr J. G. Percival, as Percival & Co., 34 King Street, Covent Garden. This was changed in 1893 to Rivington, Percival & Co.; and in 1897 the firm was enabled to revive its previous title of Rivington & Co., maintaining large educational and theological connexions with the Moderate and High Church party.

Smith, Elder & Co.—George Smith (1), the founder of this firm, was born in Scotland in 1789, and died 1846. From Scotland he migrated to London, where he found employment first with Rivingtons, St Paul's Churchyard, and afterwards with J. Murray. In 1816, together with a fellow Scotsman, Alexander Elder, he commenced business at 158 Fenchurch Street as booksellers and stationers; and in 1819 they added publishing to their business. It was here that George Smith (2) was born, on 19th March 1824; and in the same year the business was removed to 65 Cornhill, a house which was afterwards justly celebrated in literary and business circles. At the age of fourteen George Smith (2) came into the business, and shortly afterwards took over the control of the publishing department. His father dying in 1846, the responsibility of the business devolved principally upon his son, and under his management increased by leaps and bounds, multiplying thirteen times in twenty years. A large portion of the business was connected with foreign agencies and banking, especially with India. This was relinquished in 1868 in favour of Messrs H. S. King & Co. Mr Smith removed the publishing business to Waterloo Place. Here the literary side of his career was extended and developed; he exerted considerable influence upon men and letters, encouraging young writers and laying the foundation of lasting friendships. For over thirty years Mr G. Smith (2) was the friend and publisher of John Ruskin, and it was with him that *Jane Eyre* found a publisher in 1847. In 1855 was started the *Overland Mail* and the *Homeward Mail*, journals which still have a large circulation. By this firm were issued works by W. M. Thackeray, Mr and Mrs Browning, Wilkie Collins, Matthew Arnold, Miss Martineau, James Payn, and Mrs Humphry Ward. In 1866 was published Anthony Trollope's *Last Chronicles of Barset*, for which £3000 was paid. In January 1860 the first of the three great ventures connected with Mr Smith was commenced, the *Cornhill Magazine* being issued in that month, under the editorship of W. M. Thackeray, with whom was associated many of the brilliant writers of the period. The second venture was the founding of the *Pall Mall Gazette*, the first number appearing on 7th February 1865, price 2d. The third and most important venture in Mr Smith's career was the publication of *The Dictionary of National Biography*, the first volume being issued in 1882; it was completed in 1901, consisting in all of 66 volumes; and this monumental work was the crowning effort of a successful career. Mr George Smith died on 6th April 1901. In 1894 Mr George Smith's son-in-law, Mr Reginald J. Smith, entered the firm, and afterwards became sole acting partner.

Blackwood, W., & Sons.—The house of Blackwood owes its origin to William Blackwood, who was born of humble parents at Edinburgh on the 20th November 1776. At the age of fourteen he was apprenticed to Bell & Bradfute. In 1797 he entered the employment of Mundell & Co., Glasgow. In 1800 he joined Mr Ross, a bookseller and book auctioneer; but finding the old-book trade more to his liking, he left Edinburgh for London, where he remained three years. Returning to Edinburgh in 1804, he opened an old-book shop in Princes Street, selling old, rare, and curious books. He undertook the Scotch agency for John Murray and other London publishers, and gradually drifted into publishing on his own account. On 1st April 1817 was issued the first number of the *Edinburgh Monthly Magazine*, which on its seventh number bore the name of *Blackwood's* as the leading part of its title, by which it has ever since been known. "Maga," as this magazine soon came to be called, was the organ of the Scottish Tory party, and round it gathered John Wilson ("Christopher North"), Maginn, Lockhart, Lord Neaves, Carlyle, Moir, Lord Lytton, Galt, Aytoun, and Mrs Oliphant. William Blackwood died on the 10th September 1834, and was succeeded by his two sons, Alexander and Robert. In 1829 they removed to the premises they now occupy in George Street; and in 1845 Alexander Blackwood died, and was shortly afterwards followed by his brother Robert. A younger brother, John, who was born in 1818, succeeded to the business; four years later he was joined by Major William Blackwood, who continued in the firm until his death in 1861. In 1862 John Blackwood took into partnership the Major's elder son, William, who, with his uncle, largely developed the business until John's death in 1879. John Blackwood was a man of strong personality and great business discernment; it was he who introduced George Eliot to the world of letters. He also inaugurated the "Ancient Classics for English Readers" and other important series, while the many great writers who had their works issued from this house are too numerous to catalogue. The present head of the firm is Mr William Blackwood, assisted by his two nephews, Mr George W. Blackwood and Mr J. H. Blackwood.

Cassell & Co. Limited.—John Cassell, the founder of this firm, was born at Manchester on 23rd January 1817, and died on 1st April 1865. Starting in humble life, he educated himself, and early gained a considerable knowledge of English literature, and also attained a proficiency in French. In 1836 his energies became centred in the temperance movement, in which he laboured with eloquence and zeal. He started a temperance publishing office in the Strand, and at the same time did a large trade in tea and coffee. A few years after he developed a more influential business in La Belle Sauvage Yard, Ludgate Hill. Messrs Petter and Galpin became partners, and added greatly to the business by the issue of good literature for the working classes, one of the most useful being the *Popular Educator*, which was followed by the *Technical Educator*. The firm also published the *History of Julius Cæsar*, by Napoleon III., and the English edition of the illustrated works of Gustave Doré. The business is now under the control of a limited company, who produce all their own serial and other publications.

Chambers, W. & R.—The elder of the two pioneers of popular literature, William Chambers, was born at Peebles on 16th April 1800, his brother Robert two years later. From the village school they obtained the foundation of an education by which, with industry and perseverance, they were enabled to gain for themselves a knowledge which was almost encyclopædic. Each brother started separately a small shop, with a capital of a few shillings, selling some of their old school-books, doing printing, and producing some of the books they sold. Robert early developed a literary taste, writing in all seventy volumes, besides innumerable articles, among the former being the *Vestiges of the Natural History of Creation*, the authorship of which was not, however, acknowledged until after his death. On the 4th February 1832 appeared the first number of *Chambers's Edinburgh Journal*, which met with immediate success, reaching a circulation of 50,000 copies of its weekly issue. This brought the two brothers together as partners, Robert supervising the literary part of the concern, William being business manager. In 1844 appeared the *Cyclopædia of English Literature*, from 1860 to 1868 the famous *Chambers's Encyclopædia*, and in 1864 that remarkable work, the *Book of Days*. Robert Chambers died at St Andrews on 17th March 1871. His brother William had accepted the offer of a baronetcy, but died on 20th May 1883, before it could be bestowed. The business is now a limited company, and beside educational and general literature, it publishes a large number of books for juveniles.

Chapman & Hall Limited.—This firm commenced business in 1834 at 186 Strand, removing in 1850 to 193 Piccadilly, and in 1881 settled in Henrietta Street, Covent Garden, where it has continued to carry on the business of publishing. Charles Dickens wrote *The Pickwick Papers* for them. They afterwards published many of Dickens's works; but in 1844 they quarrelled, and Dickens transferred his publishing to Bradbury & Evans. This breach was healed in 1859; and at the death of Dickens, Frederick Chapman bought the entire copyright of Dickens's works. This firm also published works by Mr and Mrs Browning, Anthony Trollope, Carlyle, and George Meredith; and in 1865 they started the *Fortnightly Review*, of which G. H. Lewes was the first editor. This magazine was originally issued twice a month, but in 1867 it was changed to a monthly periodical. In 1880 the firm became a limited company under the managership of Mr Frederick Chapman (1823–95), and the business is now continued as general publishers.

Gardner (Wells), Darton & Co.—The head of this firm, Mr Joseph W. Darton, is the successor in a long line of ancestry, all of whom have maintained a high position in the issue of books for children. The first, William Darton (Darton & Harvey, Gracechurch Street), was born in 1755 and died in 1816. He, his son William Darton (2) (1781–1854), and grandson, John Maw Darton (1810–81), were members of the Society of Friends. For over half a century this firm almost monopolized the trade in children's books. Amongst their early publications was the *Original Poems* by Jane and Ann Taylor. They also issued works by Priscilla Wakefield, Maria Hack, Peter Parley, Mrs Sherwood, and William and Mary Howitt. In 1857 Mr J. W. Darton joined the firm of Wells Gardner & Co., who publish *Chatterbox*, *Sunday*, and works in juvenile and devotional literature.

Heinemann, William.—Mr William Heinemann was born at Surbiton on 18th May 1863, and after some years of experience with the late Nicholas Trübner, he established himself as a publisher on 1st January 1890. In 1893 Mr Sydney S. Pawling, a nephew of the late C. E. Mudie, the librarian, joined him in partnership. Mr Heinemann married, in 1899, Magda Stuart-Sindici ("Kassandra Vivaria"). He is himself the author of several plays, and, besides issuing the later works by Mr Hall Caine and other popular novelists, he has introduced into England translations of many important and artistic works from the Continent.

Low (Sampson), Marston & Co. Limited.—Sampson Low, the founder of this firm, was born in London in November 1797. He was the son of Sampson Low, printer and bookseller, Soho Square, was apprenticed at a circulating library in Bond Street, and afterwards entered the employ of Longmans & Co. In 1819 he

commenced business at 42 Lamb's Conduit Street as a bookseller and stationer. In connexion with Mr William Longman and other publishers, he started in 1837 *The Publishers' Circular*, which became Low's property in 1867. In this journal a list of new books is printed, and from these lists the *Annual Catalogue* of books is issued, the first volume appearing in 1839. From these volumes the *British Catalogue* was compiled, followed by the *English Catalogue of Books*, the only bibliographical work of reference for new books. In 1848 Low opened a publishing office in Red Lion Court, which in 1852 was removed to Ludgate Hill, where he greatly developed his publishing business, and also added to it a depôt for the sale of American books. He died on 5th March 1871. In 1856 Mr Edward Marston became a partner; in 1867 the firm removed to Fleet Street, and finally to St Dunstan's House, Fetter Lane, in 1887. This firm has a large American and continental agency; they are the publishers of the *Nineteenth Century and After*, and books in various branches of literature.

ROUTLEDGE, GEORGE, & SONS LIMITED.—George Routledge, a native of Cumberland, was apprenticed at Carlisle, came to London, and found employment at the house of Baldwin, Cradock & Joy. He afterwards obtained a subordinate position under the Government, and opened a small shop in Ryder's Court, Leicester Square. In 1845 Routledge moved to Soho Square; and in 1848 he was joined in partnership by his brother-in-law, Mr William Warne, and afterwards by Mr F. Warne. The firm then removed to Farringdon Street, where they successfully developed a business in issuing cheap literature, giving Lord Lytton £20,000 for the right to issue a cheap edition of his works for a term of ten years. They also issued the works of G. P. R. James, Harrison Ainsworth, Mayne Reid, and James Grant. Among the various "libraries" they started were the "Railway" and the "Popular." In 1865 Mr F. Warne terminated his partnership and established a fresh business in Bedford Street. Mr Routledge's business was removed to the Broadway, where his two sons, Robert and Edmund, were associated with him. Mr George Routledge died 13th December 1888, Mr Robert Routledge 23rd July 1899, and Mr Edmund Routledge on 25th August 1899.

BELL, GEORGE, & SONS.—This business was founded by George Bell in 1840, as a publisher of works in educational, classical, and general literature. Upon the retirement of Mr H. G. Bohn they purchased from him his various "libraries" of standard, classical, and other branches of literature, numbering in all 766 volumes. During recent years great attention has been given by this firm to fine art publications and to the production of artistically illustrated works.

ALLEN, GEORGE.—When John Ruskin decided to sever his connexion with Messrs Smith, Elder & Co., he selected his lifelong friend, Mr George Allen, of Orpington, Kent, to sell his books to those who wanted them. It was a strange campaign against the publisher and bookseller, but by this action Ruskin added one more to the long list of publishers. It was in 1873 that this country publishing business was inaugurated; and from that time a gradual development took place, until it was found desirable to remove Mr Allen's establishment to London. Here the business has greatly increased; and besides the works of Ruskin, books in all departments of literature have been issued.

BLACKIE & SON LIMITED.—This firm, which was founded in 1809 by John Blackie, has been largely engaged in the canvassing trade, but during recent years has developed an important publishing business in books for boys and girls, issuing annually a large number of books by G. A. Henty and others.

VIRTUE, H., & CO. LIMITED.—George Virtue, one of the leaders in the book-canvassing business, was born at Coldstream, Berwickshire, in 1793, but early in life came to London, and in 1820 was established as a religious book-remainder buyer near the Houses of Parliament. He frequently reissued these books in parts for canvassers, who made calls upon people at their houses who subscribed for the books thus issued. On the 15th July 1821 he was given an interest in Pierce Egan's *Life in London, or the Adventures of Tom and Jerry*, illustrated by I. R. and G. Cruikshank. This work caused great excitement, and was freely bought and imitated. In 1831 he moved to Paternoster Row, where he issued for canvassers Fletcher's *Guide to Family Devotion*, of which 30,000 copies were sold. Virtue also arranged with W. H. Bartlett to produce a series of fine art works descriptive of various countries of the world. The first issued was *Switzerland*, of which 20,000 copies were sold. He also produced *Scotland*, at a cost of £40,000. In 1849 the *Art Union* passed into his hands; the title of this magazine he changed to *The Art Journal*, which to this day maintains a high reputation for artistic merit. George Virtue died on the 8th December 1868: but some years before his death the business had been transferred to his son, Mr J. S. Virtue. The firm is now a limited company, under the chairmanship of Mr Herbert Virtue, and has important and extensive printing and binding premises in the City Road, London.

CAMBRIDGE UNIVERSITY PRESS.—The London business of this press was established at 17 Paternoster Row in 1873. Previous to that period it had confined its energies to producing books which were sold through the various bookselling agencies. One of their most important undertakings was the issue, in connexion with the Oxford University Press, of the Revised Version of the New Testament in 1881, and the Old Testament in 1885. They also issue an important collection of classical works in the "Pitt Press Series." This term was given to the series from the building at Cambridge erected by money subscribed to perpetuate the memory of William Pitt. The business was formerly under the management of Mr C. J. Clay, and is now conducted by his two sons, Messrs J. & C. F. Clay.

CHATTO & WINDUS.—John Camden Hotten, the originator of this firm, was born in 1832. He was a man of considerable literary ability, compiling a *Slang Dictionary* and various works on topography and family history. In 1854 he commenced business in Piccadilly as a publisher and seller of rare and curious books. Hotten died in 1873, and was succeeded by Mr Andrew Chatto. He, with his partners, have developed an important publishing business, especially in fiction and *belles lettres*.

OXFORD UNIVERSITY PRESS.—This press trades under three different imprints, namely: 1. *Oxford, printed at the University*, for Bibles, prayer-books, &c; 2. *Henry Frowde, Oxford University Press Warehouse*, for miscellaneous works not issued under the authority of the delegates; 3. *The Clarendon Press*, for classical and especially erudite works. The Clarendon Press publications were formerly issued through the agency of Macmillan & Co., but in 1874 a London business was opened under the management of Mr Henry Frowde. Besides a large and important trade in the United Kingdom and in America in Bibles, prayer and other books in handsome and rare bindings, they publish a large number of educational and classical works. The Clarendon Press holds the perpetual copyright of Clarendon's *History of the Rebellion*; the profits from this book were the means by which a part of the Clarendon Press buildings at Oxford were erected.

HURST & BLACKETT LIMITED succeeded, about 1840, to the business established by Henry Colburn in 1807. The principal trade of this firm has been the issue of fiction in three-volume form. These works were formerly sold to fiction distributors, who bound them and sold them to the libraries. Upon the establishment of Mudie's Library in 1842 this system broke down, since Mr C. E. Mudie arranged to buy the sheets himself and bind them up according to the demand. Publishers then adopted the method of issuing novels bound up in cloth. The firm is now known for its cheap and well-selected fiction.

NELSON, THOMAS, & SONS.—Thomas Nelson was born at Throsk, in Scotland, in 1780; he received his business training in London, but returned to Edinburgh, where he opened a shop, selling such works as Baxter's *Saints' Rest*, Booth's *Reign of Grace*; and in connexion with Peter Brown published the works of Paley, Romaine, and Newton. The business was greatly increased by the exertions of his two sons, William and Thomas, who were admitted as partners. Among their successes were the issue of popular juvenile literature, especially by A. L. O. E. and R. M. Ballantyne. Thomas Nelson died on 23rd March 1861. Messrs Nelson & Sons have a large and important printing and binding establishment in Edinburgh, but the publishing business is mainly carried on in Paternoster Row. Mr G. M. Brown, M.P., who married the daughter of Thomas Nelson (2), is now the acting partner.

NISBET, JAMES, & CO. LIMITED.—James Nisbet, the son of a Scottish farmer, was born on 3rd February 1785. Early in his career he came to London, and commenced business in Castle Street in 1809, where he was interested in the issue of many religious works, by Edward Irving, Dr Hamilton, and Dr MacDuff. He died on 8th November 1854. Mr James Murray succeeded to the management of the business, and he was followed by Mr Watson. The business is now a limited company, publishing works in all branches of literature.

SIMPKIN, MARSHALL, HAMILTON, KENT & CO. LIMITED.—The founder of this large publishing and distributing agency was Benjamin Crosby. He relinquished business in 1814 in favour of his two assistants, W. Simpkin and R. Marshall. In 1828 Simpkin retired, and Mr John Miles took the financial management of the concern. This firm were the London agents for Tennyson's first poems, publishing in 1827 *Poems by Two Brothers*. Marshall died on 17th November 1863, and the business remained entirely in the hands of Mr Miles's sons, under whose management it greatly developed. The firm published, among other works, O'Meara's *Napoleon at St Helena*, and *Dame Europa's School*; but their business is principally as distributing agents for the supply of miscellaneous books to the booksellers of town and country. In 1889 an amalgamation was effected between Simpkin, Marshall & Co., Hamilton, Adams & Co., and Kent & Co., being converted into a limited company, to which in 1891 was added a large wholesale newspaper distributing agency.

DENT, J. M., & CO.—As a pioneer of cheap but tastefully produced reprints in all classes of literature this firm is pre-eminent. Mr Dent was born at Darlington, and at eighteen came to London,

where he commenced business as a bookbinder. With the instincts of a true book-lover, he felt the want of cheap but well-edited books, and this induced him to commence the publishing business which he has carried on with such marked success. The "Temple" Bible, Shakespeare, and classics have had immense sales. The business was started at Great Eastern Street, but is now carried on at 29 Bedford Street, W.C., the premises once occupied by Macmillan & Co. With Mr J. M. Dent is associated his son Mr Hugh Dent.

LANE, JOHN (The Bodley Head, Vigo Street). Mr John Lane originally started publishing with Mr Elkin Mathews during the 'eighties, and by degrees their devotion to *belles lettres*, and particularly their successful discernment in encouraging the young poets of the day, made their establishment famous. The "Bodley Head" became identified with this new generation of literature, and with such writers as Mr William Watson, Mr Richard Le Gallienne, and Mr John Davidson. In 1898 the partnership was dissolved, and Mr Lane continued to carry out the same publishing policy on his own account.

CLARK, T. & T. (38 George Street, Edinburgh), originally founded by Thomas Clark in 1821, publishers of works in theology, philosophy, and general literature.—HODDER & STOUGHTON (27 Paternoster Row), publishers of theological, devotional, and general literature; also *The Bookman, The British Weekly, Expositor*, &c.—HUTCHINSON & Co. (34 Paternoster Row), with a large export and colonial trade. Publish principally fiction, biography, and travel.—METHUEN & Co. (36 Essex Street, Strand), founded 1889; principal publications, fiction, poetry, and biography.—NUTT, DAVID (57–59 Long Acre), founded 1829, dealer in foreign, classical, and general literature; publishes works in philology, folk-lore, &c.—PAUL (KEGAN), TRENCH, TRÜBNER & Co. LIMITED (20 and 22 Charing Cross Road), exporters and dealers in scientific and general literature, and publishers of works in various branches of science. This firm succeeded to the business of Nicholas Trübner and Kegan Paul, Trench & Co.—RICHARDS, GRANT (Leicester Square), founded 1897, publisher of fiction, juvenile, and most departments of literature.—SONNENSCHEIN (SWAN) & Co. LIMITED (6 White Hart Street, Paternoster Square), founded 1878, educational, scientific, and general publishers.—STANFORD, EDWARD (12, 13, and 14 Long Acre), founded 1852, military and geographical publishers, agents for the Geological Survey maps.—UNWIN, T. FISHER (11 Paternoster Buildings), founded 1883, publisher of "The Story of the Nations," and works in fiction and general literature. WARD, LOCK & Co. LIMITED (Salisbury Square), founded 1861, publishers of cheap and miscellaneous literature. With this firm is incorporated Moxon & Co., S. O. Beeton, and A. D. Innes & Co.—ARNOLD, EDWARD (37 Bedford Street, Strand), publisher of fiction and general educational literature.—BRADBURY, AGNEW & Co. LIMITED (Bouverie Street, Fleet Street), publishers of sporting and general literature; also proprietors and publishers of *Punch*.—CONSTABLE (ARCHIBALD) & Co. LIMITED (2 Whitehall Gardens), publishers of the Victorian County Histories, fiction, and other works in general literature. — WARNE (FREDERICK) & Co. (Bedford Street, Strand), founded 1865, publishers of fiction, poetry, and cheap reprints.—CHURCHILL, J. & A. (7 Great Marlborough Street, W.), the oldest publishing house which deals exclusively with medical books; it was established in 1825 by John Churchill.

AMERICAN PUBLISHERS.

APPLETON, D., & Co., was founded in 1825 by Daniel Appleton, who opened a small store in Exchange Place, New York, for the importation of foreign publications. His son, William H. Appleton, became a partner in 1838. In 1831 they published their first book, entitled *Daily Crumbs from the Master's Table*, of which they sold 2000 copies. In 1835 Mr William H. Appleton went abroad as the representative of the firm. He was entertained in England by John Murray, of whom he became a lifelong friend, and by Thomas Norton Longman. In Germany he met Baron Tauchnitz. In 1838 the firm assumed the familiar title of "D. Appleton & Co.," which it has borne ever since. In 1848 Daniel Appleton retired, dying the following year. The firm was reorganized by his sons, with William H. Appleton at its head. Under his direction several important enterprises were undertaken: the publication of the *New American Cyclopædia*, under the editorship of George Ripley and Charles A. Dana; and the publication of scientific and educational books, which has since been a feature of the house. William H. Appleton died in 1899, being the last of the second generation. The business, a large one, is now conducted by his son, William W., and the sons of his brothers, John A. and Daniel Sydney. Their growing business caused many removals, until they entered their present quarters in Fifth Avenue in 1902. Their most noted publication of recent times has been *David Harum*, which has been through nearly 100 editions, reaching the enormous total of over 650,000 copies. A branch house is maintained in London.

CENTURY CO., THE.—In 1870 Mr Roswell Smith and Dr J. G. Holland united with Charles Scribner & Co. to found *Scribner's Monthly*, Dr Holland being the editor. In 1873 *St Nicholas*, an illustrated magazine for children, was started, with Mrs Mary Mapes Dodge as editor. In 1881 the Scribner interest was bought out, a new company (The Century Co.) formed, and the name of *Scribner's Monthly* changed to *The Century Magazine*. The most notable series of articles that have appeared in the magazine are: the "Civil War Series," contributions by the surviving officers of the war, including several by General Grant; Mr Kennan's articles on "Siberia and the Exile System"; and the "Life of Abraham Lincoln," by his private secretaries Nicolay and Hay. The business of the Century Co. has steadily grown since its founding. Its best known publications are: *The Century Dictionary* (1888–91), the cost of which was nearly $1,000,000; *The Century Cyclopædia of Names, The Century Atlas*, and the series of hymn-books prepared by Dr Robinson. In 1892 the first president of the company, Mr Roswell Smith, died. His successor, Mr Frank H. Scott, is still president.

DODD, MEAD & Co. was established in New York in 1839 by M. W. Dodd and John S. Taylor, in the old Brick Church Chapel, a building then standing on what is now the site of the *New York Times*, and in that year published Cruden's *Concordance*. Various changes have occurred in the personnel of the firm, which, when it assumed its present title in 1876, included Frank H. Dodd, Edward S. Mead, and Bleecker van Wagoner. Mr Mead died in 1894. Notable publications of the house are E. P. Roe's books, *The International Cyclopædia* (1885), and *The Bookman*, started in 1895.

HARPER & BROTHERS was established in New York in 1817 by John and James Harper, under the name of J. & J. Harper. In 1825 their two younger brothers, John Wesley and Fletcher Harper, were admitted to partnership, and in 1833 the firm name was changed to Harper & Brothers. In 1840 their mechanical establishment occupied several buildings on both sides of Cliff Street, just behind their present quarters on Franklin Square; and in 1850 they erected in Franklin Square a large and commodious structure, which was connected with the Cliff Street buildings. In 1853 the entire establishment was destroyed by fire. It was at once rebuilt, with increased facilities, on the same site, and is still occupied. For many years the business was carried on as a partnership, the members of the firm being the sons and grandsons of the original founders. Their best known publications are: *Harper's Magazine, Harper's Bazaar*, and *Harper's Weekly*. In 1893 the firm was incorporated as a stock company, and so continued until its reorganization in 1901, when the control and the presidency was turned over to Colonel George Harvey, editor and proprietor of the *North American Review*. The house has a London branch.

HOUGHTON, MIFFLIN & Co.—The publishing firm of Hurd & Houghton was established in 1864, consisting of Melanchthon M. Hurd of New York and Henry Oscar Houghton of Boston. Mr Houghton already owned the "Riverside Press" in Cambridge, Mass., which he had established in 1849, and in which the manufacture of books published by the firm has since been carried on. In 1866 Albert G. Houghton, elder brother of the founder, was admitted to the firm; and in 1872 Horace E. Scudder and George H. Mifflin became members, the former retiring after three years. In 1873 the house bought *The Atlantic Monthly*. In 1878 Albert G. Houghton and Mr Hurd retired, and the firm was consolidated with James R. Osgood & Co., successors to Ticknor & Fields, and the name changed to Houghton, Osgood & Co. Two years later Mr Osgood retired, and the firm became Houghton, Mifflin & Co. In 1895 H. O. Houghton, the founder, died. As now constituted, Mr Mifflin is senior partner, and has associated with him sons of Henry O. and Albert G. Houghton, James Murray Kay, and L. H. Valentine. The manufacturing business at the "Riverside Press" is carried on under the name of H. O. Houghton & Co., although identical with the publishing firm. Among the publications of the firm are the works of Emerson, Lowell, Holmes, Longfellow, Whittier, Hawthorne, and Fiske. They also published the *Narrative and Critical History of America*.

LEE & SHEPARD.—A partnership between William Lee and Charles A. B. Shepard was formed in Boston in 1861. Beginning as booksellers, they developed into a publishing business. Mr Shepard died in 1889, and Mr Lee continued as sole partner until 1897, when he sold his entire business, including the firm name, to E. Fleming & Co., bookbinders. Mr Lee continued with the firm until 1898.

LIPPINCOTT Co., J. B.—In 1794 Jacob Johnson opened a small book-store in Market Street, Philadelphia. Later, as Johnson & Warner, Warner & Grigg, and Grigg, Elliot & Co., the business was successively and successfully carried on until 1850, when it was purchased by Joshua B. Lippincott and became known as Lippincott, Grambo & Co. A large building was erected at Market and Filbert Streets during the Civil War. In 1885 a

joint-stock company, capitalized at $1,000,000, was formed and given the present name. In January of the following year Mr Lippincott died. In 1899 a fire destroyed not only the Market Street building, but also a large stock of books and plates. In 1901 the company built and equipped a new five-storey building at Locust and Sixth Streets. *Chambers's Encyclopædia* and *Lippincott's Magazine* are two of their important publications.

LITTLE, BROWN & Co. was founded in 1784 in Boston by E. Batelle. He was succeeded by Benjamin Guild, Samuel Cabot, William T. and Samuel Blake. In 1806 William Andrews succeeded to the business, and later, Jacob A. Cummings and William Hilliard. In 1821 the firm became Carter, Hilliard & Co. In 1827 a new firm was formed, under the title of Hilliard, Gray & Co., the company being Charles C. Little. The name for a time was Hilliard, Gray, Little & Wilkins. In 1837 Mr Little and James Brown became the proprietors, under the name of Charles C. Little & James Brown. In 1847 Augustus Flagg was admitted to the firm. Mr Little died in 1869, and Mr Brown in 1855. Mr Flagg continued as managing partner until his retirement in 1884. The present firm consists of John Murray Brown, Charles W. Allen, Hulings C. Brown, and James W. M'Intyre. Besides law-books, the firm has published several standard works both of American and of foreign authors.

PUTNAM'S SONS, G. P.—In 1836 George Palmer Putnam became a partner in the firm of Wiley & Long, which a year later became Wiley & Putnam. In 1849 he established the first American bookselling house in London. In 1848 he separated from Mr Wiley and instituted the firm of G. P. Putnam & Co. In 1853 *Putnam's Monthly* was established, which in 1872, after the death of Mr Putnam, was transferred to Scribner's, and was an important factor in the foundation of the first *Scribner's Monthly* (now *The Century Magazine*). In 1866 the firm became G. P. Putnam & Son. In 1841 Mr George Haven Putnam organized the first of the committees charged with the work of securing an American international copyright law. In 1872 the firm became G. P. Putnam's Sons, the additional partners being John Bishop Putnam and Irving Putnam. In 1879 they reinstituted a branch in London, and their publications have since borne the imprint "New York and London." In 1893 they established, at New Rochelle, New York, the "Knickerbocker Press." In 1896 they assumed the publication of the literary monthly *The Critic*. The present head of the house is George Haven Putnam.

SCRIBNER'S SONS, CHARLES, was established in New York City in 1846 by Charles Scribner, sen., and Isaac D. Baker, as Baker & Scribner. Mr Baker retired after a few years, and Charles Scribner continued the business until 1857, when he united with Charles Welford. This partnership, under the name of Scribner & Welford, was separate from the main house, and was organized for the purpose only of importing books. On the death of Mr Welford in 1885 the two departments were combined. In 1864 Mr Scribner admitted to partnership Andrew C. Armstrong, and in 1869 Edward Seymour. Mr Scribner died in 1871, and was succeeded by his eldest son, John Blair Scribner, and the firm now became Scribner, Armstrong & Co., and that of the importing house Scribner, Welford & Armstrong. Mr Seymour died in 1877, and a year later John Blair Scribner and Charles Scribner, his younger brother, purchased the interest of Mr Armstrong, and the present firm name was adopted. The death of John Blair in the next year left Charles the only partner until 1884, when his brother Arthur H. joined him. In 1894 the firm erected a handsome edifice in Fifth Avenue, which it now occupies. In 1881 they sold their interest in *Scribner's Monthly*, the name of which was changed to *The Century Magazine*, the Scribners agreeing to abstain for five years from the publication of a similar magazine. In 1887 the present *Scribner's Magazine* was started. Among the notable achievements of the house was the importation and sale of the *Encyclopædia Britannica* (9th edition).

Other important American publishing houses are: LOTHROP PUBLISHING Co., which succeeded D. Lothrop & Co., founded by Daniel Lothrop in 1850.—DOUBLEDAY, PAGE & Co. succeeded Doubleday, M'Clure & Co. The firm consists of F. N. Doubleday, Walter H. Page (formerly editor of *The Atlantic Monthly*), Henry W. Lanier, J. Leslie Thompson, and S. A. Everitt. Their publications include books by Kipling, Crockett, Anthony Hope, and others, and two monthly magazines—*The World's Work* and *Country Life in America*.—E. P. DUTTON & Co., established in Boston in 1852, but removed to New York in 1869. Their publications are largely of a religious nature.—A. C. M'CLURG & Co., a Chicago firm, established in 1848 by S. C. Griggs, which developed, after several changes, into the present firm. The guiding spirit for nearly forty years was General A. C. M'Clurg, who died in 1899. The firm suffered from three great fires, the last in 1899, after which the present corporation was formed. They are the largest publishers in the West.—At the head of educational publishers stand THE AMERICAN BOOK Co., incorporated under the laws of the state of New Jersey in 1890, with a capital of $5,000,000. It purchased the school and college text-books previously owned by Ivison, Blakeman & Co., A. S. Barnes & Co., Van Antwerp, Bragg, & Co., D. Appleton & Co., and the common school-books owned by Harper & Brothers. Two of these firms closed their business, and the new corporation started with stockholders, directors, and officers largely made up from the partners in the former houses. They now publish various series of school-books, which are most widely used throughout the United States, and have issued many new books that have met with wonderful success. Their annual output approximates ten million volumes. The main offices of the company are at New York, Chicago, and Cincinnati, with distributing centres at other important points.—D. C. HEATH & Co., Boston, established in 1886, publish a considerable number of educational works.—MAYNARD, MERRILL & Co. are publishers of school and college text-books.

FOREIGN FIRMS.

TAUCHNITZ, BERNHARD (Leipzig).—The founder of this famous house, Baron Christian Bernhard von Tauchnitz, was born in 1816, the nephew of the noted German printer and bookseller, Karl C. T. Tauchnitz. His establishment at Leipzig was founded by him in 1837, and his name is associated with the Library of British Authors, now numbering between 2000 and 3000 volumes. In 1860 he was ennobled, and in 1877 was made a life member of the Saxon Upper Chamber. He held for many years (1866–95) the office of British Consul-General for the kingdom and duchies of Saxony. He died on the 13th of August 1895, and the publishing business is carried on by his son, Baron Christian Karl von Tauchnitz, Dr. Juris., who is likewise British Consul-General.

BROCKHAUS, F. A. (Leipzig).—The founder, Friedrich Arnold Brockhaus, was born in 1772 and died in 1823. This business was first started at Altenburg in 1811, but removed to Leipzig in 1818. It is now under the management of Messrs Albert (president of the Publishers' Association, 1901) and Rudolf Brockhaus, who carry on an immense publishing and manufacturing business. They issue *Ersch and Gruber's Encyclopædia*, the important *Konversations-Lexikon*, and many historical and bibliographical works.

Other important German houses are:—TEUBNER, BAEDEKER, MEYER, TRÜBNER, and BREITKOPF & HÄRTEL.

DIDOT (Paris).—This house was founded by François Didot, who was born in 1689 and died 1757, being succeeded by his sons F. A. and P. F. Didot, who greatly distinguished themselves by the improvement they made in printing. The house has a long and distinguished history, and is associated with bookselling, paper-making, and bookbinding in all its branches.

HACHETTE & Co. (79 Boulevard St Germain, Paris, and 18 King William Street, W.C.).—Established in 1826 by Louis Hachette, born 5th May 1800 and died 31st July 1864. He founded several series of works, including the notable "Bibliothèque Populaire," the "Bibliothèque Variée," and many others. M. René Fouret is the present (1902) head of this firm.

The following are also important French houses:—A. COLIN & CIE (Paris), CH. DELAGRAVE (Paris), CALMANN LÉVY (Paris), G. MASSON (Paris), HETZEL & CIE (Paris), DESCLÉE DE BROUWER ET CIE (Paris, Lille, Brussels, and Tournai), A. MAINE & FILS (Tours).

Pudsey, a municipal borough of Yorkshire, England, in the Pudsey parliamentary division of the West Riding, 6 miles south-west of Leeds, on the Great Northern Railway. Since 1894 it has been controlled by an urban district council. Recent buildings include Baptist, Free, and Primitive Methodist chapels. A small public park was opened in 1889. Part of the parish, Tyersall, is in the borough of Bradford. Population (1881), 12,314; (1891), 13,444; (1901), 14,907.

Pudukota, a state of southern India, in subordination to Madras, lying between the British districts of Tanjore and Madura. Area, 1101 square miles. Population (1881), 302,127; (1891), 373,096, showing an increase of 23 per cent.; average density, 339 persons per square mile. In 1901 the population was 380,582, showing an increase of 2 per cent.

The chief, whose title is Tondaman, is of the Kallar or robber caste. His ancestor received a grant of territory for loyal services during the wars in the Carnatic at the end of the 18th century. The present raja, aged twenty-three, has been educated by an English tutor, and visited England in 1898. Estimated gross revenue, Rs.10,00,000, exclusive of land revenue granted to junior branches of the family, to Brahmans, and to temples; no tribute. In 1897–98 the expenditure on public works was Rs.1,18,000; number of schools, 368. The town of PUDUKOTA is situated in 10° 23′ N. and 78° 52′ E. Population (1891), 16,885.

Puebla, a town of Spain, island of Majorca, on the north coast, with a railway station. The population was 5681 in 1887, and 5877 in 1897. It is a clean, well built town. In the neighbourhood there are marshes, lagoons, and flat alluvial plains that afford excellent grazing ground for live stock. Puebla has a parish church and several convents.

Puebla, a state of Mexico, bounded on the N. and E. by Vera Cruz, on the S. by Oaxaca and Guerrero, on the W. by Morelos, Mexico, and Hidalgo. Area, 12,207 square miles. Population (1879), 784,466; (1900), 1,024,446. Agriculture is the principal industry; the chief products are cereals, sugar-cane, coffee, vanilla, and a variety of fruits. The value of the cereals produced in 1897 is given as $8,746,999 (Mexican currency), and of sugar-cane, $786,307. The state is divided into twenty-one districts. The capital, PUEBLA, or Puebla de los Angeles, with a population of 88,684, is one of the oldest and most important cities of Mexico, possessing many handsome buildings, among others the cathedral, and the state college with a large library, the palace of justice, school of medicine with the Palafoxiana Library of over 100,000 volumes. It is an important commercial and industrial centre, with numerous cotton and woollen mills, glass factories, foundries, and other establishments. The Mexican Railway and the Inter-Oceanic Railway pass through it. Among the chief towns are: Teziutlan (9776), Tlatlauquitepec (8754), Atlixco (7698), Tehuacan (7275), Matamoros (7184), Zautla (7053), Cholula (7031), Chalchicomula (6913), Ixtamaxtitlan (6699), Zacatlan (6226), Acatlan (5883), San Juan de los Llanos (5742), Cuetzalan (5176).

Pueblo, a city of Colorado, U.S.A., capital of Pueblo county, on both sides of the Arkansas river, at the mouth of Fountain creek, south-east of the centre of the state, at an altitude of 4656 feet. It is regularly laid out, mainly in the level bottom land of the river, is divided into eight wards, has Holly system waterworks, owned by the city, and is sewered. It is, next to Denver, the largest city in the state, and is an important railway centre, being entered by the Atchison, Topeka, and Santa Fé, the Chicago, Rock Island, and Pacific, the Denver and Rio Grande, the Colorado and Southern, and the Missouri Pacific. In 1900 it contained 241 manufacturing establishments, with a total capital of $12,374,248. They employed on an average 4911 wage-earners, and the product was valued at $30,795,481. Pueblo is the largest smelting point west of Missouri river, and besides smelters and blast furnaces, contains rolling and other mills for the manufacture of iron and brass. The assessed valuation of real estate was, in 1898, $7,980,327, and the net debt was $1,108,052. Population (1880), 3217; (1890), 24,558; (1900), 28,157, of whom 4705 were foreign-born and 1213 negroes.

Pueblo Nuevo del Mar, a seaport of Spain, in the province of Valencia, on the Mediterranean coast to the north of the mouth of the river Guadalaviar, near the Valencia and Tarragona Railway. It has straight, regular, well-built streets, divided in two by the little river Rinet. There is a lighthouse installed in a tower of the church of Los Angeles. The theatre and casino are only used in summer, when the Valencians come down. Population (1887), 11,291; (1897), 13,100, but these figures are much increased from June to September.

Puenteareas, a town of Spain, province of Pontevedra, south-east of Vigo, on the river Tea, in a hilly country abounding in vines, hemp, wheat, rye, oats, oranges, and fruit, where live stock is extensively reared. The industries are porcelain manufactures, tanning, and distilling. The town has a large, handsome square, well-built streets, good shops, and an old parish church. Close by are the ruins of the castle of Sobroso, that played an important part in mediæval civil wars. Population (1887), 13,286; (1897), 13,342.

Puente Genil, a town of Spain, in the province of Cordoba, on the banks of the Genil. It is on the Cordoba-Malaga line, and is the starting-point of the line to Linares. A bridge joins the lower part of Puente Genil with the higher, built on rising ground extending to the olive groves above. The principal industry is the manufacture of olive oil in eighty mills. There are also flour-mills and linen factories. The *alhondiga* or permanent market is always well stocked with grain, vegetables, and live stock. The streets and squares are all regular and well built. The suburbs extend far into the country. There are two large parish churches and several convents, schools for primary and higher education, hospitals, a municipal library, and a theatre. Population (1887), 11,406; (1897), 11,645.

Puerto Cabello, a town of Venezuela, the third port of the republic, situated on the Caribbean Sea, about 45 miles from Valencia by rail and 65 miles from La Guaira. Population, over 15,000. There are some handsome buildings, among others the custom-house, the city hall, the theatre, the hospital, the railway station, and two churches. In 1900 the port was visited by 267 ships, of 218,788 tons burden. The value of the imports for the same year was £340,693, and the exports were: coffee, 12,994 tons; cacao, 455 tons; hides and skins, 1276 tons; and lumber, 274 tons.

Puerto de Santa Maria, a seaport and town of Spain, in the province of Cadiz, on the right bank of the river Guadalete, with a station on the railway from Cadiz to Seville. The most important industry is the wine trade, and there are modern glass, liqueur, alcohol, starch, and soap manufactures. There is a bull-ring accommodating 12,000 persons, large markets, town-hall, an iron bridge across the river, and several hospitals. The primary and higher schools are in the hands of the Jesuits. The parish church, begun in the 13th century, was completed in the 17th. It resembles the Seville Cathedral. Population (1877), 22,125; (1897), 20,630.

Puerto Principe, the chief interior town of the province of Camaguey, in Cuba. It was founded by Velasquez, lieutenant of Diego Columbus, governor of Hispaniola, in 1515, and claims to be the most creole of Cuban towns. It stands upon a plain about midway between two coasts, and is connected by rail with Nuevitas to the north-east. Population (1899), 25,102.

Puerto Real, a town of Spain, province of Cadiz, to the north of San Fernando, at the end of the Bay of Cadiz, with a station on the line from Seville to Cadiz. It is a bathing resort in summer. The port has good quays, a dry dock of the Spanish Transatlantic Company, connected with their important works, and safe anchorage close to the wharves for the largest steamers. The town has fine squares, and broad, well-built streets, a noble town-hall, many schools, a bull-ring, fine promenades, several convents, and a parish church that is a good specimen of architecture of the 16th century, with three naves and a remarkable atrium. The industries are important, and there is an active trade in wine and oils. Puerto Real was founded in 1488 by Ferdinand and Isabella. Population (1897), 9772.

Puket, known to the Chinese as TONGKA, the capital town of the island of Junkseylon and the chief Siamese

port on the west coast of the Malay Peninsula. It is situated on the eastern side of the island, in 7° 54′ N. and 98° 24′ E. It is the residence of the chief commissioner of the west coast, and has a population, chiefly Chinese, of about 20,000. The town may be briefly described as a gigantic tin-mine. The output declined, owing to a variety of causes, during the 'nineties, and may be stated at from 2000 to 3000 tons annually. The improvement in the price of tin and the lowering of the royalty demanded by the Siamese Government, assisted by the establishment of a branch office of the Mining Department in the place, should all tend to restore the former prosperity of the port.

Pulkovo (PULKOWA), a village of Russia, in the province and 10 miles from the city of St Petersburg. It contains the Pulkovo Observatory, on a hill 248 feet high, consisting of a main building, with several towers for various instruments, and a special small observatory for the officers of the Geodetical Section of the General Staff Academy. (See OBSERVATORY in the ninth edition of this work for an account of the instruments.) Attached to the university there is a library of 15,000 volumes and 20,000 pamphlets. Sixteen volumes of "Observations" and about 500 separate works have been published by the Observatory since its foundation.

Pulley Block.—Pulley blocks are now very generally made of metal, the block being built up of light steel or wrought iron stampings bolted together, and the sheaves being of cast iron or steel, or of bronze in the smaller sizes.

In order that the sheaves may turn freely on the pin and not become set hard by corrosion, they should, if made of iron or steel, have an inner bearing surface or "bush" of bronze. Although hempen rope may be and is used with metal pulley blocks, steel wire rope frequently takes its place, and this conduces to a further reduction in the weight of the block. Hempen ropes are, however, generally used when hand power is applied directly to the rope, as wire rope is not suitable for handling. A very effective pulley tackle is known as the differential pulley or "Weston's pulley." It depends for its efficiency on the mechanical principle involved in the old Chinese windlass. Chains are necessarily used with this tackle in place of rope, both for the sake of handling and to prevent the chain from slipping and the load from falling. The sheaves of the upper and lower blocks are recessed to suit the links of the chain. The two sheaves of the upper block are fixed together and turn as one; these sheaves slightly differ in diameter, so that one sheave may have one more recess for a link than the other. The chain, passing over the larger sheave of the upper block, is led through the sheave of the lower block, returned in the opposite direction over the smaller sheave of the upper block, and the free ends connected together. From this arrangement it results, that if by means of the free end of the chain the sheaves of the upper blocks are revolved once, the chain is wound on the large sheave and off the small sheave, the load at the same time being lifted an amount equal to half the difference. This pulley block is largely used in factories and workshops, and generally for lifting loads of a few tons. Its chief defect lies in the tendency of the chains to kink and jam the pulleys, and this has led to the introduction of other devices for weight lifting. Conspicuous among these is an arrangement of tackle in which the upper sheave is rotated by a worm and worm wheel, the lifting chain passing from an upper sheave to the pulley block below, from which it is returned and made fast to the upper block. The worm of the worm wheel is turned by a hanging chain which passes loosely over a wheel in the worm shaft. Tackle of this kind sometimes has the upper sheaves actuated by an epicyclic train of toothed wheels. All the above devices possess the great advantage of holding the load in suspension, but in consequence they necessarily work with much frictional loss. (G. H. BA.)

Pullman, formerly a town of Cook county, Illinois, U.S.A., now a part of Chicago. It was built entirely by the Pullman Car Company, and was composed of the car-shops and homes of the employés. The company owns all the property, and formerly exercised jurisdiction over it. In many respects it was a model town, with excellent municipal institutions. The population has never been separately returned by the census.

Pulszky, Franz Aurel (1814–1897), Hungarian politician and author, was born on the 17th of September 1814, at Eperjes. After studying law and philosophy at the high schools of his native town and Miskolcz, he travelled abroad. England particularly attracted him, and his fascinating book, *Aus dem Tagebach eines in Grossbritannien reisenden Ungarns* (Pesth, 1837) gained for him the membership of the Hungarian Academy. Elected to the Reichstag of 1840, he was in 1848 appointed to a financial post in the Hungarian Government, and was transferred in like capacity to Vienna under Esterhazy. Suspected of intriguing with the revolutionists, Pulszky fled to Budapest to avoid arrest. Here he became an active member of the Committee of National Defence, and when obliged to fly the country he joined Kossuth in England and with him made a tour in the United States of America. He was condemned to death (1852) *in contumaciam* by a council of war. In 1860 he went to Italy, took part in Garibaldi's expedition to Aspromonte (1862), and was interned as a prisoner of war in Naples. Amnestied by the Emperor of Austria in 1866, he returned home and re-entered public life; was from 1867–76, and again in 1884, a member of the Hungarian Reichstag, joining the Déak party. In addition to his political activity, he was president of the literary section of the Hungarian Academy, and director of the National Museum at Budapest, where he became distinguished for his archæological researches. He employed his great influence to promote both art and science and Liberal views in his native country. He died on the 9th of September 1897. Among his literary works must be mentioned *Die Jacobiner in Ungarn* (1887), *Ideen zur Philosophie der Geschichte Ungarns* and *Eletem és Levrom* (4 vols., 1882).

Pułtusk, a town of Russian Poland, in the government of Warsaw, 56 miles south-west of Łomża and 36 miles from Ostrolenka railway station, on the right bank of the Narew. It is well built, and has woollen, linen, and hosiery mills, copper works, and potteries. Population (1897), 15,878.

Punjab, The (*panj-ab* = "five rivers"), a province of British India, under the administration of a lieutenant-governor. It includes three classes of native states: (1) a number of old rajput principalities in the Himalaya, some of which are very small; (2) a collection of scattered states in the eastern plains, mostly under Sikh rulers; and (3) the Mahommedan state of Bahawalpur, running along between the river Sutlej and Rajputana. Kashmir is excluded from the Punjab, as being in direct political relations with the Governor-General. Total area (including native states), 148,966 square miles. Total population (1891), 25,130,127; (1901), 26,888,300. The capital is Lahore. In November 1901 the area of the Punjab was reduced by the creation of the North-West Frontier province.

Population.—The table on next page gives the area and population of the Punjab, according to the census of 1891 and that of 1901. Between 1881 and 1891 the rate of increase was 10·71 per cent. for British districts and 10·42 for native states, and between 1891 and 1901, 7·6 per cent. for British districts and 4·1 per cent. for the native states. In both cases the highest rate of increase was to be found in the western plains and in the submontane tracts, where irrigation has been most extended. In the eastern plains, where population is already dense, the increase has been less. The average density in British districts is 173 persons per square mile, ranging from 633 in Jullundur and 620 in Amritsar to only 74 in the Derajat. Classified according to religion, in British districts only, Mahommedans in 1891 numbered 11,634,192, or 55·8 per cent. of the population, being proportion-

ately more numerous than in any other part of India except Sind and Kashmir. They are found chiefly along the valley of the Indus, where they represent immigration from Afghanistan. In the neighbourhood of the old Moghul capital of Delhi they form only 23 per cent. Hindus numbered 7,743,477, or 37 per cent., being most numerous in the hills and along the Jumna. In the native states the proportion rises to 58 per cent. Sikhs numbered 1,389,934, or 6·6 per cent., being most numerous in the neighbourhood of Amritsar and Ferozepore, but they nowhere form as much as one-third of the inhabitants. Since 1881 they have increased more rapidly than the general population, except in the native states, where they show an actual decrease. But the distinction between a Sikh and a Hindu Jat is not very easy to determine. Buddhist and Jains numbered 45,245, or ·2 per cent., of whom the Buddhists are to be found almost entirely in Kangra, and the Jains in the eastern plains. Christians numbered 53,587, or ·3 per cent., of whom 30,839 were Europeans and 3111 Eurasians, leaving 19,637 for native converts, chiefly in the districts of Sialkot, Gujranwala, and Gurdaspur. "Others" numbered only 412, aborigines not being distinguished in the Punjab census.

Agriculture.—Out of a total area of 70,718,720 acres, the area assessed to land revenue is 49,598,193 acres, at the average rate of a little more than 8 annas (say 8d.) per acre. In 1897–98 the total cultivated area was 18,515,957 acres, of which 8,720,408 acres were irrigated from canals and wells in almost equal proportions. The principal crops are wheat, millet, pulse, barley, maize, oil-seeds, rice, cotton, and sugar-cane. In 1897–98 the area under indigo was 94,615 acres, chiefly in Multan and Muzaffargarh; the area under tea was 10,064 acres, almost entirely in Kangra. Irrigation has been greatly extended. Perhaps the most important work of this kind in India is the Chenab canal, which has altogether changed the face of the Rechna Doab, a thirsty upland tract between the Chenab and the Ravi. An elaborate system of colonization has been successfully introduced, and rail-

way extension has proceeded at the same time. During the five years between 1893 and 1898 the area irrigated from the Chenab canal rose from 157,197 to 810,000 acres. A new district has thus been created, with its headquarters at Lyallpur, called after a late lieutenant-governor. The entire canal system of the Punjab consists of 3323 miles of main channels and 8089 miles of distributaries, upon which Rs.8,90,93,390 has been expended, yielding a net revenue of Rs.95,29,130, or 10·7 per cent. on the capital outlay.

Industries.—The Punjab possesses no great industries, like the cotton of Bombay or the jute of Bengal. There are four cotton mills, at Delhi and Lahore, with 406 looms and 46,932 spindles, employing 2014 persons, of whom 1656 are adult males. The out-turn in 1897–98 was more than 6 million ℔ of yarn, chiefly of counts between Nos. 11 and 17, and 1 million ℔ of woven goods, chiefly *dhutis*, T-cloths, and grey goods. There is also one woollen mill at Dhariwal, with 128 looms and 4320 spindles, employing 834 persons, and producing 700,000 ℔ of goods, valued at Rs.813,550. There are seven breweries, mostly at hill stations, the oldest of which dates from 1852, with a total out-turn of about 2¼ million gallons of beer. Coal is mined for railway purposes at two places in the salt range in Jhelum district. In 1898 the total output was 85,862 tons, valued at Rs.7,18,950, and the number of persons employed was 1803. The development of both collieries is hindered by the difficulty of procuring labour. Factories for cleaning and pressing cotton are numerous. There are flour-mills at Delhi, carpet factories at Amritsar, and a sugar factory at Gurdaspur. The Punjab is well supplied with railways, which have their central terminus at Delhi. One main line of the North-Western runs from Umballa through Lahore and Rawalpindi to Peshawar, on the extreme frontier; another main line runs from Lahore to Multan, and thence to the sea at Karachi; while a third will run along the left bank of the Indus, from Attock southwards. From Delhi to Umballa there are two lines, one of the North-Western through Meerut and Saharanpur in the North-West Provinces, and a more direct one of a company, which is continued to Kalka, at the foot of the hills, whence a further continuation to Simla is under construction. The south-east of the province is served by two branches of the Rajputana system, which have their termini at Delhi and Ferozepore; and also by the Southern Punjab, which runs from Delhi to Bhawalpur. The total length of railways in British districts is about 2000 miles.

The *foreign trade* is registered with six countries—Tirah, Kabul, Bajaor, Kashmir, Ladakh, and Chinese Tibet. The total value of both imports and exports is about Rs.2,50,00,000, of which more than half belongs to Kashmir. The chief imports are *ghi* (clarified butter), timber, wool, *charas* (an intoxicating preparation of hemp), fruits, rice, and skins. The chief exports are cotton piece-goods, cotton twist and yarn, sugar, tea, salt, indigo, brass, and copper. The internal trade with other provinces of India is valued at about Rs.12,00,00,000 for imports and Rs.8,00,00,000 for exports. Almost the whole of this is conducted by rail, the river-borne trade on the Indus having dwindled to only Rs.10,00,000 for imports and Rs 40,00,000 for exports. The wheat trade is almost entirely conducted by rail with Karachi, and depends upon the demand in Europe. It is liable to great fluctuations, the quantity exported in 1897–98 being more than double that in the preceding year.

The *administration* is conducted by a lieutenant-governor, who is appointed by the governor-general, subject to the approval of the Crown. The secretariat consists of a secretary, a junior secretary, and two under secretaries. Two financial commissioners take the place of the board of revenue in most other provinces. A survival of the "non-regulation" system is to be found in the title of deputy-commissioner for the district officer elsewhere called collector. The highest judicial authority is styled the chief court, now consisting of six members, which corresponds to the high court elsewhere. A legislative council of nine nominated members, of whom four are natives of India, was created in 1897; but the privileges of interpellation and of discussing the financial statement have not yet been extended to the council. The province is distributed into six divisions or commissionerships and thirty-one districts. Most of the commissioners also exercise political functions over the native states within their jurisdiction. In 1897 the total number of police of all kinds was 19,506, of whom just half were provided with fire-arms. The number employed on police duty proper was 7938, being one policeman to every 13·9 square miles of area and to every 2628 of population.

In 1897–98 the total *revenue* of the province amounted to Rx.3,916,031, of which Rx.2,438,671 was derived from land. The total civil expenditure amounted to Rx.2,023,821, the whole of which was covered by profits from railways and irrigation. Since the reorganization of the Indian army in 1894 the Punjab has formed an independent command, under a lieutenant-general, with headquarters at Murree, a hill sanitarium not far from the great military station of Rawalpindi. The command consists of three first-class districts (including the Punjab frontier force) and two second-class districts. The Punjab frontier force is composed of five batteries of artillery, four regiments of cavalry, and nine regiments of infantry—all natives. The remaining native regiments retain their former numbers in the Bengal army. In 1898 the Punjab command consisted of 20,337 British and 46,232 native troops: total, 66,569. In addition, there were three battalions of volunteer rifles, with an enrolled strength of 2020.

The total number of *municipalities* is 148, with an aggregate population of 2,120,372 (1891). In the majority of these at least two-thirds of the municipal committee are elected by the ratepayers, who take considerable interest in the privilege. At the contested elections in 1897 more than half the ratepayers voted. The total number of members is 1671, of whom 1546 are Indians, and 815 are elected. In 1897–98 the aggregate municipal income was Rs.44,22,324, of which Rs.31,41,078 was derived from taxation, chiefly octroi, the average incidence of taxation being R.1.7.6 per head. The aggregate expenditure was Rs.43,96,972, of which Rs.18,76,462 was devoted to public health and convenience, Rs.6,71,420 to public safety, and Rs.5,98,499 to education. The aggregate amount of debt outstanding was Rs.37,14,738, chiefly raised by the four municipalities of Lahore, Delhi, Simla, and Dera Ghazi Khan. In every district except Simla there is a district board, and in most of the districts there are also subordinate local boards; out of a total of 2494 members, 1153 are elected. The district boards, on the whole, work satisfactorily; but the local boards are of little use. In 1897–98 the total local fund income was Rs.31,23,315, of which Rs.24,09,900 was derived from provincial rates. The total expenditure was Rs.31,12,528, of which Rs.8,57,438 was devoted to public works, Rs.6,64,651 to education, and Rs.4,03,418 to medical and sanitary charges.

Education.—The following table gives the chief statistics of education for the two years 1886–87 and 1896–97:—

Class of Institution.	1886–87.		1896–97.	
	Schools.	Pupils.	Schools.	Pupils.
Colleges . . .	5	509	10	1,409
Secondary schools . .	245	44,808	346	61,128
Primary schools . .	1,934	89,702	2770	119,046
Special schools . .	19	995	18	2,155
Private institutions .	16,527	145,145	5363	82,184
Total .	18,730	281,159	8507	265,922

The totals in this table are misleading, for they include private institutions, such as Koran schools attached to mosques, which are specially numerous, but cannot be said to give any valuable instruction. As a matter of fact, schools under the Education Department, and particularly those which teach English, have progressed more rapidly than in any other province. The pupils in them have increased during the five years ending 1897 by no less than 31 per cent., while students in arts colleges have nearly doubled. Including private institutions, the proportion of male pupils to the estimated male population of school-going age (15 per cent. of the total male population) is 14·5 per cent., compared with 22·3 per cent. for India generally. The proportion of female pupils is 1·5 per cent., compared with 2·3 per cent. for India generally.

The following table gives the expenditure on education according to sources for the same two years:—

Source of Revenue.	1886–87.	1896–97.
	Rs.	Rs.
Provincial revenues	7,47,746	7,27,394
Local funds	4,89,269	6,41,001
Municipal funds	3,06,270	3,37,203
Fees	2,48,951	7,98,590
Other sources	4,64,927	5,68,526
Total . .	22,57,163	30,72,714

The increase in expenditure has fairly kept pace with the increase in pupils; but during the last few years almost the whole of the increase has been borne by fees, which now contribute no less than 26 per cent. of the total. In secondary schools alone the proportion rises to 60 per cent., and in colleges to 43 per cent. This is another indication of the extent to which English education has been accepted by the people. The Punjab University, which was founded in 1882, differs from other Indian

universities in being more than a merely examining body. It is responsible for the management of the Oriental College at Lahore, and it takes a part in the improvement of vernacular literature. It also conducts Oriental examinations side by side with those in English, and has been the first to introduce a series of examinations in science from matriculation to the degree, as well as a final school examination in clerical and commercial subjects. During the five years ending 1897 the total number of students who matriculated was 4397; 437 graduated B.A. and 51 M.A., while 34 passed examinations in law and 181 in medicine.

The Punjab has not altogether escaped recent visitations of plague and famine. Plague, fortunately, never spreads in an epidemic form, being almost entirely confined to a few villages in Jullundur district, where it persisted for more than a year. The total number of deaths from plague throughout the province from October 1897 to April 1899 was 1920. In the winter of 1901–02 a severe outbreak of plague occurred, causing as many as 2000 deaths in a week. The famine of 1896–97 was most severely felt in the Delhi division, and especially in Hissar district adjoining the desert of Rajputana, where at one time 15 per cent. of the inhabitants were in receipt of relief. For the province generally the maximum number on relief was 127,758 in the middle of March 1897. The total expenditure was Rs.22,34,004. The famine of 1899–1900 was more widely spread, but was again most severe in Hissar, where the cattle died in hundreds through scarcity of fodder. The maximum number on relief in May 1900 was 180,000 in British districts and 50,000 in native states.

(J. S. CO)

Punta Arenas, a town of Chile, capital of the territory of Magallanes, situated in 53° 10′ S. and 70° 54′ W. Population (1895), 3227. The estimated population in 1900 was 6419. It is the only free port in Chile. It has grown with phenomenal rapidity; a few years ago a poor village, it has now fine buildings, broad streets, is lighted by electricity, and bids fair to become a large city. Its principal commerce is in wool, skins, beef (salted and dried), lard, and tallow. Numerous steamers belonging to European lines touch there monthly. A highroad 170 kilometres in length joins the town to the Argentine colonies of Gallegos and Santa Cruz.

Puri, or JAGANNATH, a town and district of British India, in the Orissa division of Bengal. The town is on the seacoast, and has a railway station. Population (1881), 22,095; (1891), 28,794. As containing the world-famous shrine of Jagannath, Puri is perhaps the most holy and most frequented of all Hindu places of pilgrimage. Sanitation is effected by the Puri Lodging-House Act, which provides for the appointment of a special health officer, and for the licensing of lodging-houses both in the town and along the pilgrims' route. It has a high school, with 159 pupils, a literary club, and a students' association.

The district of PURI has an area of 2473 square miles; population (1881), 888,592; (1891), 944,998; (1901), 1,017,286, showing an increase of 6 per cent. between 1881 and 1891, and of 7·6 between 1891 and 1901; average density, 411 persons per square mile. Classified according to religion, Hindus in 1891 numbered 927,514; Mahommedans, 15,597; Christians, 841, of whom 41 were Europeans; "others," 1046. Land revenue and rates (1897–98) were Rs.6,58,325; number of police, 388; boys at school (1896–97), 22,310, being 31·3 per cent. of the male population of school-going age; registered death-rate (1897), 39 per thousand. In the Orissa famine of 1866 more than one-third of the population of Puri is said to have perished. The district suffered from drought in 1897, but it is now protected by the East Coast Railway, which was opened throughout from Calcutta to Madras in 1891, with a branch to Puri town.

Purnea, a town and district of British India, in the Bhagalpur division of Bengal. The town is on the left bank of the little river Saura, with a railway station. Population (1881), 15,016; (1891), 14,555. It has a bad reputation for fever. The high school had 249 pupils in 1896–97, and there is a technical school with 15 pupils.

The district of PURNEA has an area of 4993 square miles. Population (1881), 1,849,073; (1891), 1,944,658; (1901), 1,877,072, showing an increase of 5 per cent. between 1881 and 1891, but a decrease of 3·5 per cent. between 1891 and 1901; average density, 376 persons per square mile. Classified according to religion, Hindus in 1891 numbered 1,138,738; Mahommedans, 805,267; Christians, 387, of whom 114 were Europeans; "others," 266. Land revenue and rates (1897–98) were Rs.12,80,230; number of police, 570; boys at school (1896–97), 20,035, being 13·4 per cent. of the male population of school-going age, compared with 28·3 per cent. for Bengal generally; registered death-rate (1897), 32 per thousand. Jute is grown to some extent, but the principal industry is indigo. There are 7 indigo concerns and 14 factories, with a capital of Rs.13,45,000, employing 8000 persons, with an out-turn of 5000 maunds, valued at Rs.9,00,000. The district is traversed by two branches of the Eastern Bengal Railway, running out north, and a third branch, parallel to the Ganges, is under construction.

Purulia, a town of British India, headquarters of Manbhum district in Bengal, situated in 23° 19′ N. and 86° 24′ E., with a station on the Bengal–Nagpur Railway. Population (1881), 9805; (1891), 12,128. It is a growing centre of trade, with large imports of rice during the scarcity of 1896–97, and has a high school, with 339 pupils in 1896–97.

Purus. See AMAZON.

Putnam, a town and included city of Windham county, Connecticut, U.S.A. It has an area of 27 square miles of hilly country, situated in the north-eastern part of the state. The city of Putnam is on the Quinebaug river, at the intersection of two branches of the New York, New Haven, and Hartford Railway, and at an altitude of 287 feet. In 1900 it contained 93 manufacturing establishments, with a capital of $2,019,685, 1631 employés, and products valued at $1,928,803. Population of the town (1880), 5827; (1890), 6512; (1900), 7348: of the city in 1900, 6667, of whom 2012 were foreign-born and 81 negroes.

Putney, a district in the county of London, in the borough of Wandsworth (to which parliamentary division it has since 1885 belonged), on the right bank of the Thames about 8 miles above London Bridge by river, with a station on the South-Western Railway. In 1890 a new cemetery was opened to meet the needs of the district. Population (1881), 13,221; (1891), 17,771; (1901), 24,139.

Putumayo. See AMAZON.

Puvis de Chavannes, Pierre Cécile (1824–1898), French painter, was born at Lyons, 14th December 1824. His father was a mining engineer, the descendant of an old family of Burgundy. Pierre Puvis was educated at the Lyons College and at the Lycée Henri IV. in Paris, and was intending to follow his father's profession when a serious illness interrupted his studies. A journey to Italy opened his mind to fresh ideas, and on his return to France he announced his intention of becoming a painter, and went to study first under Henri Scheffer, and then under Couture. On leaving this master in 1852, he established himself in a studio in the Place Pigalle (which he did not give up till 1897), and there organized a sort of academy for a group of fellow-students who wished to work from the living model. Puvis first exhibited in the Salon of 1850 a "Pietà," and in the same year he painted "Mademoiselle de Sombreuil drinking a glass of blood to save her father," and "Jean Cavalier by his Mother's Deathbed," besides an "Ecce Homo," now in the church of Champagnat (Saône-et-Loire). In 1852 and in the two following years Puvis's pictures were rejected by the Salon, and were sent to a private exhibition in the Galeries Bonne-Nouvelle. The public laughed at his work as loudly as at that of Courbet, but the young painter was none the less warmly defended by Théophile Gautier, and Banville. For nine years Puvis was excluded from the Salons. In 1857 he had painted a "Martyrdom of St Sebastian," "Meditation," "Village Firemen," "Julie," "Herodias," and "Saint

St Geneviève Watching over Sleeping Paris. By Puvis de Chavannes.

(In the Pantheon, Paris.)

Camilla" — compositions showing a great variety of impulse, still undecided in style and reflecting the influence of the Italian masters as well as of Delacroix and Couture. In 1859 Puvis reappeared in the Salon with the "Return from Hunting" (now in the Marseilles Gallery). But not till he produced "Peace" and "War" did he really impress his critics, inaugurating a vast series of decorative paintings. For these two works a second-class medal was awarded to him, and the State offered to purchase the "Peace." Puvis, not choosing to part the pair, made a gift of "War" to the State. He then set to work again, and in 1864 exhibited "Autumn" and "Sleep," but found no purchasers. One of these pictures is now in the Lyons Museum, and the other at Lille. "Peace" and "War" were placed in the great gallery of the Museum at Amiens, where Puvis completed their effect by painting four panels: a "Standard-Bearer," "Woman Weeping over the Ruins of her Home," a "Reaper," and a "Woman Spinning." These works were so much admired that further decorations were ordered for the same building, and the artist presented to the city of Amiens "Labour" and "Repose," for which the municipality could not afford to pay. At their request Puvis undertook another work, intended for the upper landing of the staircase, and in 1865 a composition entitled "Ave Picardia Nutrix," allegorical of the fertility of the province, was added to the collection. In 1879 the city wished to complete the decoration of the building, and the painter, again at his own expense, executed the cartoon of "Ludus pro Patria," exhibited in the Salon of 1881 and purchased by the State, which at the same time gave him a commission for the finished work, which gained for the artist in the following year the first-class medal of the Society of French Artists. While toiling at these large works, Puvis de Chavannes rested himself by painting easel pictures. To the Salon of 1870 he had sent a picture called "Harvest," a work introductory to his paintings in the Picardy Gallery; the "Beheading of John the Baptist" figured in the Great Exhibition of 1889; a "Magdalen" is in the collection of M. Chéramy (Paris). Then followed "Hope" (1872), the "Family of Fisher-Folk" (1875), and "Women on the Seashore" (1879). Still, these canvases, however interesting, are not to be named by the side of his grand decorative works. Among these must be noted those in the Palais Longchamp at Marseilles. These two paintings, ordered in 1867, represent "Marseilles as a Greek Colony" and "Marseilles, the Emporium of the East." After these, Puvis executed for the town-hall of Poitiers two decorative paintings of historical subjects: "Radegund, in seclusion at the convent of Sainte-Croix, affords a refuge to poets," and "Charles Martel, in the year 732, saves Christendom by defeating the Saracens at Poitiers." The Pantheon in Paris also possesses a decorative work of great interest by this painter: "The Life of Saint Geneviève," treated in three panels. In the first we see the saint's childhood, and in the second and third her life as a shepherdess, the two being surmounted by a frieze, also divided into two subjects. In 1876 the Department of Fine Arts in Paris gave the artist a commission to paint "Saint Geneviève giving Food to Paris" and "Saint Geneviève watching over Sleeping Paris" (see Plate), in which he gave to the saint the features of Princess Cantacuzene, his wife, who died not long before he did. At the time of his death—24th October 1898—the work was almost finished. After completing the first paintings in the Pantheon, which occupied him for three years and eight months, Puvis de Chavannes undertook to paint the staircase leading to the gallery of fine arts in the Lyons Museum, and took for his subjects the "Vision of the Antique," a procession of youths on horseback, which a female figure standing on a knoll points out to Pheidias; the "Sacred Grove"; and two allegorical figures of "The Rhône" and "The Saône." It was in the same mood of inspiration by the antique that he painted the hemicycle at the Sorbonne, an allegory of "Science, Art, and Letters," a work of great extent, for which he was paid 35,000 francs (=£1400). In this he has symbolized Eloquence, Philosophy, History, Geology, Mineralogy, and Physics with wonderful artistic feeling and sense of decorative treatment. At the Hôtel de Ville in Paris, again, Puvis decorated the grand staircase and the first reception-room. These works employed him from 1889 till 1893. In the reception-room he painted two panels: "Winter" and "Summer," the mural paintings on the staircase, which had previously been placed in the hands of Baudry and of Delaunay, are devoted to the glory of the attributes of the city of Paris; "Patriotism," "Charity," "Artistic Gifts," "Learning," "Wit," "Fancy," "Beauty," "Courage," "The Worship of the Past," "Industry," "Urbanity," and "Poetry." On the ceiling we see Victor Hugo offering his lyre to the city of Paris. The pictures in the Rouen Museum (1890–92) show a different vein, and the artist's power of conceiving and setting forth a plastic scheme enabling him to decorate a public building with beautiful human figures and the finest lines of landscape. He took for his theme the three sections of the museum: "Antiquities," "Ceramics," and "The Fine Arts," entitling his allegory "Inter Artes et Naturam." We see here toilers raising a colossal monolith, part of some ancient monument, to add it to other architectural pieces; then the busy scene of a pottery; and finally artists painting in the open air. Puvis, as a rule, adhered to the presentment of the nude or of the lightest drapery; here, however, in response to some critical remarks, he has clad his figures exclusively in modern dress. The importance given to the landscape in this work is also worthy of note; it is broadly treated, and in a purely decorative manner. Nor was it for France alone that Puvis de Chavannes executed decorative works. After prolonged negotiations, begun so early as in 1891, with the trustees of the Boston Library, U.S.A., he accepted a commission to paint nine large panels for that building, to be inserted in separate compartments, three facing the door, three to the right, and three to the left. These pictures, begun in 1895, were finished in 1898. For the centre panel, to which the others are subsidiary, he chose as the title "The Inspiring Muses hailing the Herald Genius of Light." In the eight others we find "Bucolic Poetry," "Dramatic Poetry," "Epic Poetry," "History," "Astronomy," "Physics," and "Chemistry." In these works of his latest period Puvis de Chavannes soars boldly above realistic vision. In the figures which people the walls with poetic images he endeavours to achieve originality of the embodying forms, and at the same time a plastic expression of ideas born of a mind whose conceptions grew ever loftier, while yet the artist would not abandon the severe study of nature. Such works as the great paintings at Amiens, Rouen, Marseilles, the Pantheon, the Sorbonne, and the Hôtel de Ville are among the most important productions of French art in the 19th century. Puvis de Chavannes was president of the National Society of Fine Arts (the New Salon). His principal pupils and followers are Ary Renan (died 1900), Baudouin, J. F. Auburtin, and Cottet.

(H. Fr.)

Puy, Le, or Puy-en-Velay, chief town of department Haute-Loire, France, 313 miles south-south-east of Paris,

on the railway to St Étienne. It contains the Montredon asylum for the departments of Loire and Haute-Loire, an institution for deaf mutes, municipal industrial schools of drawing, architecture, and mathematics applied to arts and industries, and schools of lace-making for poor children. About ninety establishments are engaged in the manufacture of lace and guipure, and there is a noted distillery. Electric tramways connect the town with Brives-Charensac and Espalay-St-Mareil. Population (1881), 15,459; (1891), 16,640; (1901), 20,570.

Puy-de-Dôme, a department of central France, traversed by the mountains Dore, Dôme, and Du Forez, and watered by the Allier.

Area, 3090 square miles. The population, 566,064 in 1881, had decreased to 529,181 in 1901. Births in 1899, 9821, of which 396 were illegitimate; deaths, 10,785; marriages, 3872. There were, in 1896, 1371 primary schools, with 79,000 pupils, there being 4 per cent. of the population illiterate. Out of 1,672,190 acres of land cultivated in 1896, 834,860 acres were plough-land and 106,210 acres vineyards. Of the rest two-sevenths were wood land and five-sevenths grass land. The department in 1899 produced wheat valued at £780,000; rye, £520,000; barley, £166,000; oats, £278,000; potatoes, £544,000; mangold-wurzel, £96,000; beetroot, £72,000; vines, £304,000. Its live stock included 15,910 horses, 265,110 head of cattle, 352,040 sheep, 132,100 pigs, and 18,580 goats. Mining in 1898 turned out 384,000 metric tons of coal, valued at £160,000; 750 tons of peat, 1324 tons of lead and copper, and 10,000 tons of alum and bitumen. The metallurgic industry is, however, in a backward state. The well-known cutlery of Thiers employs (1896) 12,000 workmen. Much is done in sugar-refining at Billom, and there is a busy industry in caoutchouc around Clermont-Ferrand, the capital (52,017 in 1901).

Pwllheli, municipal and contributory parliamentary borough (Carnarvon district), seaport, and market-town of Carnarvonshire, Wales, 20 miles south of Carnarvon, on the shore of Tremadoc Bay, with a terminal station on the Cambrian Railway. It has a sandy beach 4 miles in extent. There is a promenade near the sea, and the scenery around is very picturesque. Stone obtained from Gimlet Rock is worked into setts and shipped to various ports. Population (1891), 3231; (1901), 3675.

Pyrenees, a range of mountains in south-west Europe, separating the Iberian peninsula from France. The more careful examination of the chain by members of the English and French Alpine Clubs has considerably modified our views with respect to its general character, the southern versant having been shown to be the more important of the two. It has been recognized, as shown in the maps of MM. Schrader, de St Sand, and Wallon, that, taken as a whole, the range must be regarded, not as formed on the analogy of a fern-frond or fish-bone, with the lateral ridges running down to the two opposite plains, but rather as a swelling of the earth's crust, the culminating portion of which is composed of a series of primitive chains, which do not coincide with the line of partition of the water, but cross it obliquely, as if the ground had experienced a sidewise thrust at the time when the earth's crust was ridged up into the long chain under the influence of contraction. Both the orderly arrangement of these diagonal chains and the agreement which exists between the tectonic and geological phenomena are well shown in the geological and hypsometrical maps published in the *Annuaire du Club Alpin français* for 1891 and 1892 by MM. Schrader and de Margerie. The primitive formations of the range, of which little beyond the French portions had previously been studied, are shown to be almost all continued diagonally on the Spanish side, and the central ridge thus presents the appearance of a series of wrinkles with an inclination (from north-west to south-east) greater than that of the chain as a whole. Other less pronounced wrinkles run from south-west to north-east and intersect the former series at certain points, so that it is by alternate digressions from one to the other series that the irregular crest of the Pyrenees acquires its general direction. Far from having impressed its own direction on the orientation of the chain at large, this crest is merely the resultant of secondary agencies by which the primitive mass has been eroded and lessened in bulk; and though its importance from a hydrographic point of view is still considerable, its geological significance is practically *nil*.

In their primitive state the Pyrenees were composed of synclinal and anticlinal folds, slightly inclined, as a rule, to the general direction of the range, and to be distinguished even at the present day in a long series of valleys which follow each other in a longitudinal direction. But the waters, in their descent from the higher ground in a north and south direction to the plains of France and Spain, have attacked these folds successively, forming, in course of time, transverse watercourses which, broadly speaking, follow the line of greatest inclination in their descent. These watercourses, which must originally have been formed of a chain of lakes and swamps at varying altitudes, united by cascades, have gradually worn down the sills which obstructed their passage, and made their way to the plains by valleys which have become more and more deep and regular. This is how, at least on the French side, the mountains eventually acquired the character of transverse chains running down from a central dividing crest. In Spain, where the lesser humidity of the atmosphere has allowed the primitive folds to retain more of their original form, these may be traced, in spite of the fluvial erosion, to right and left of the principal valleys, which have been merely cut by running water, as by a saw, across the mass of the range.

This mass of ancient formations, with the associated Silurian rocks, constitutes almost the whole of the slopes on the side of France, where the ridges pushed farthest into the plain have lost all importance, or in certain cases have entirely disappeared under the action of erosion. The case is quite different in Spain. On this southern slope the central mass is separated from the plains by two very distinct lines of high ground, which are a characteristic feature of the Pyrenean structure. These are the zone of plateaux and that of the sierras which separate the central mass of the range from the plains at its foot. The zone of plateaux forms a sort of basement, which fringes and supports the more elevated portions. Its maximum elevation scarcely exceeds 1000 metres (3280 feet), and it presents a succession of broad synclinal depressions, in which Tertiary (Miocene and Oligocene) formations, the most recent of the whole range, occupy the surface. This zone does not sink directly towards the plains. It is bordered on the outer side by high chains of sierras with anticlinal strata, which rise at certain points to a height of over 6500 feet, and which enclose the whole Pyrenean region with no further break than the narrow clefts which give passage to the running waters. The plateaux region—completely unknown but a few years ago—thus presents the appearance of a great longitudinal lake, whose waters have been drained off by a series of breaches in the outer wall.

In the zone of the sierras denudation has continued to act until it has exposed on the summits the most ancient rocks, which have been shorn of their Tertiary covering. They have, however, retained their character of longitudinal folds, parallel to the direction of the central mountains. Those which extend farthest towards the plain have been tilted up so that they rise above the latter in a steep escarpment. Originally the French side had also its plateaux and sierras, but the only traces which remain are in the region of the Corbières and the Lesser Pyrenees of the Ariège, the more active denudation nearer the ocean having removed them entirely down to the level of the plains, from before the western Pyrenees.

The arrangement of the Pyrenees in chains, gently inclined near the centre but longitudinal everywhere else, is brought out better still by observing the courses of the streams which flow down towards Spain. On the French side most of the longitudinal valleys have disappeared; and this is why the range has so long been described as sending out transverse spurs, the more important slope remaining unknown. It is, however, still possible to distinguish some traces of this formation towards the east, where atmospheric denudation has been less active. On the south the principal streams, after cutting their way through the highest zone at right angles to the general direction of the range, become involved half-way to the plains in great longitudinal folds, from which they make their escape only after traversing long distances without finding an outlet.

The unexpected importance shown by recent investigations to attach to the Spanish versant has greatly modified the values assigned only a few years back to the area and mean elevation of the Pyrenees. Instead of the 13,440 square miles formerly put down for the former, M. Schrader has obtained a value of 21,044 square miles in the light of our later knowledge. Of this total

6390 square miles fall to the northern slope and 14,654 square miles—*i.e.*, more than double—to the southern, the difference being mainly due to the zone of plateaux and sierras. The mean elevation, estimated by Élie de Beaumont at 1500 metres (4900 feet), has been sensibly diminished by the addition of that zone to the system, and we must now put it at only 1200 metres (3930 feet) for the range as a whole. We thus see the important part played by the above-mentioned plateaux of small elevation in a chain whose highest summit reaches 11,167 feet, while the passes show a greater altitude than those of the Alps. (F. SCH.)

Pyrénées-Basses, a department in the extreme south-west of France, traversed by the Pyrenees, which separate it from Spain, and washed by the Atlantic.

Area, 2978 square miles. The population, 434,366 in 1881, had decreased to 423,164 in 1901, a decrease due to emigration. In 1899 the births numbered 9542, of which 590 were illegitimate; deaths, 7988; marriages, 2738. There were in 1896, 1168 schools, with 59,000 pupils, as many as 9 per cent. of the population being illiterate. The area under cultivation in 1896 comprised 1,113,970 acres, of which only 380,380 acres were laid out in plough-land and 49,400 in vines. The wheat grown in 1899 was valued at £536,000; maize, £600,000; potatoes, £56,000; natural pastures, £444,000; vines, £372,000; chestnuts, £78,000. The live stock numbered in 1899, 25,240 horses, 14,530 asses, 155,800 head of cattle, 410,960 sheep, 130,700 pigs, and 14,300 goats. The department in 1898 raised 720 metric tons of peat, 1920 tons of copper and iron, and 16,750 tons of rock-salt. The alimentary industries are especially developed. Pau, the capital, had in 1901, 34,692 inhabitants; Bayonne, 27,601.

Pyrénées-Hautes, a department of south-western France, traversed by the Pyrenees, which divide it from Spain, and watered by the Adour and the Gave de Pau.

Area, 1750 square miles. The population, 236,474 in 1881, had declined to 212,173 in 1901. Births in 1899, 3969, of which 290 were illegitimate; deaths, 4342; marriages, 1406. There were in 1896, 856 primary schools, with 30,000 pupils, 3 per cent. of the population being illiterate. Out of a total of 674,310 acres cultivated in 1896, 271,700 acres were plough-land and 34,580 acres vineyards. The wheat grown in 1899 was valued at £308,000; meslin, £64,000; oats, £56,000; maize, £144,000; potatoes, £88,000; natural pastures, £440,000; vines, £106,000; walnuts, £24,000. The live stock included (1899) 17,400 horses, 13,000 asses, 121,770 cattle, 364,800 sheep, and 81,000 pigs. Peat is cut, and there are marble quarries. Industry is in a backward state. Tarbes, the capital, had in 1901, 26,055 inhabitants.

Pyrénées-Orientales, a department of the south of France, resting on the chain of the Pyrenees, and washed by the Mediterranean.

Area, 1599 square miles. The population, 208,585 in 1881, was 209,447 in 1901. Births in 1899, 4864, of which 211 were illegitimate; deaths, 4195; marriages, 1670. There were in 1896, 479 schools, with 33,000 pupils, 4 per cent. of the population being illiterate. The area under cultivation in 1896 amounted to 537,405 acres, of which 154,552 acres were arable and 131,594 acres were in vines. The department in 1899 raised wheat valued at £64,000; rye, £108,000; oats, £56,000; maize, £48,000; potatoes, £164,000. The vintage of 1899 was valued at £2,250,000. The department also raised in 1898, 489 cwts. of silkworm cocoons. Its live stock (1899) included 11,270 horses, 23,020 cattle, 364,800 sheep, 81,000 pigs, and 7000 goats. The mining of 1898 turned out 1750 tons of lignite and 32,000 tons of iron. The industries in metals produced 125 metric tons of cast-iron and 208 tons of iron, totalling the value of £4000. Perpignan, the capital, had in 1901, 36,157 inhabitants.

Pyrgos, a town of Greece, in the province of Elis and Achaia, 43 miles south-south-west of Patras. It is the second town in importance in the Peloponnesus, and is connected with its harbour, Katakolon, 7½ miles distant, and also with Patras and Olympia, by rail. It has frequently been injured by earthquakes. Population (1896), 12,705.

Pyrites.—Mineralogically this word is used to denote either a group of metallic sulphides or else cubic iron pyrites; miners use the term rather loosely to indicate mineral matter the bulk of which consists of sulphide of iron, which may be either true iron pyrites, FeS_2, or magnetic pyrites, Fe_7S_8, or both. Iron pyrites is one of the most widely distributed of metallic minerals, and occurs in deposits of all kinds; it is sometimes, *e.g.*, in coal seams, an injurious impurity, whilst in other cases it may be the main object of exploitation. Pyrites is largely worked for the sake of the sulphur it contains, and is used in sulphuric acid manufacture. The material thus employed may be a pure iron pyrites in the sense of containing no other metal except iron, its value then depending wholly on the proportion of sulphur it contains. Pyrites low in sulphur is incapable of sustaining its own combustion without the aid of an external source of heat, and 45 per cent. of sulphur is, for economic reasons, usually looked upon as the lowest admissible for sulphuric acid manufacture. It is also important for this purpose that the ore should be as free as possible from arsenic.

The world's annual production of iron pyrites (that is, of pyrites valuable mainly as a source of sulphur) is about 1,000,000 tons. The largest producer is France, with over 300,000 tons; the greater part of this (about 250,000 tons) comes from the Sain Bel mines in the department of the Rhone, not far from the historic copper mines of Chessy, where the deposits are in the form of large veins and of beds of mica schist highly impregnated with pyrites. Spain produces annually about 200,000 tons of iron pyrites, used merely as a source of sulphur, while the mines in the famous Huelva district produce chiefly copper pyrites—*i.e.*, iron pyrites containing a small amount of copper, the latter probably existing as disseminated chalcopyrite. Pyritic ore free from copper is also exported from the same region; for example, the Aguas Tenidas pyrites is practically free from copper, and is especially valuable on account of its freedom also from arsenic. Germany produces about 135,000 tons of iron pyrites, by far the greater part of which is derived from mines near Meggen on the river Lenne, where the ore occurs in lenticular veins intercalated between Upper Devonian shales. In many of the deposits of cupriferous pyrites in various parts of the world, certain portions which are found to be too poor to be worth treating for copper are sold as ordinary pyrites, in spite of their containing small amounts of copper. Great Britain produces about 12,000 tons of pyrites annually.

A most important group of deposits widely distributed throughout the world is that of cupriferous iron pyrites, usually spoken of commercially as copper pyrites; these are characterized by consisting mainly of iron pyrites with notable amounts of copper, sometimes silver and gold, and frequently the sulphides of lead and zinc in small proportions. The form of the deposits is generally lenticular, and they usually occur in or near the contacts of various eruptive rocks with schists or slates: there is much reason for supposing that the presence of the eruptive rocks is in some way connected genetically with the existence of these deposits. Among the best known are those already mentioned in the Huelva district of the south-west of Spain, extending also into Portugal, of which the Rio Tinto mines are the most famous, including also Tharsis, Catania, Santo Domingo (in Portugal), &c.; the Rammelsberg mines in the Harz Mountains; Agordo and Montecatini in Italy; Szomolnok in Hungary; Röros, Vigsnäs, and Sulitjelma in Norway; Falun in Sweden; Betts Cove, Tilt Cove, and Little Bay in Newfoundland; Ducktown in Tennessee; Sudbury in Canada, where the deposit is remarkable for containing a large proportion of magnetic pyrites and for its richness in nickel; and Mount Lyell in Tasmania. The products of these deposits are treated for the most part as ores of copper, no attempt being made in many cases to utilize their sulphur contents. At Rio Tinto the ore is divided into three classes:—(1) The poorest, containing 2 per cent.

of copper, averaging, say, $1\frac{1}{2}$ per cent., is treated locally by leaching with water and liquor containing ferric sulphate; by this means the copper is gradually dissolved, and is precipitated by means of pig iron; the residue is exported and sold as ordinary iron pyrites. (2) Export ore, containing between 2 and 5 per cent. of copper, in which the sulphur, copper, precious metals, and iron are all utilized, the residual oxide of iron after extraction of the other ingredients being sold under the name of "purple ore." (3) Smelting ore, which averages about 6 per cent. of copper, and is smelted after partial calcination, producing a matte with 30 to 35 per cent. of copper.

In some places the modern process of pyritic smelting is being introduced; it consists of smelting pyrites in a shaft furnace by means of a heated air blast, little or no carbonaceous fuel being used. The heat evolved by the oxidation of the greater portion of the iron and sulphur is sufficient to smelt the remaining iron, sulphur, and copper to a matte, whilst the oxide of iron formed combines with silica to form a slag. (For the further treatment of the matte so formed see COPPER.)

Pyritz, a town of Prussia, province of Pomerania, 16 miles south-south-west of Stargard by the railway to Küstrin. It is still surrounded by a mediæval wall with towers, and has two parish churches. Close by is the fountain (1824) in which Otto, bishop of Bamberg, baptized the first Pomeranian converts to Christianity in 1124. Excellent wheat is grown in the vicinity. Population (1900), 8188.

Pyrometry. See THERMOMETRY.

Quain, Sir Richard, 1st BARONET (1816–1898), Irish physician, was born at Mallow-on-the-Blackwater, Co. Cork, on 30th October 1816. He received his early education at Cloyne, and was then apprenticed to a doctor in Limerick. In 1837 he entered University College, London, where he graduated with high honours as M.B. in 1840, and as M.D. (gold medal) in 1842. Six years later he was chosen an assistant physician to the Brompton Hospital for Diseases of the Chest, and with that institution he retained his connexion until his death, first as full physician (1855) and subsequently as consultant. He became a fellow of the Royal College of Physicians in 1851, and filled almost every post of honour it could offer except the presidency, in the contest for which he was beaten by Sir Andrew Clark in 1888. He became physician-extraordinary to Queen Victoria in 1890, and was created a baronet in the following year. He died in London on 13th March 1898. Quain, who was elected a fellow of the Royal Society in 1871, was the author of several memoirs, dealing for the most part with disorders of the heart, but his name will be best remembered by the *Dictionary of Medicine*, the preparation of which occupied him from 1875 to 1882 (2nd edition, 1894; 3rd, 1902). He sat on the Royal Commission on Rinderpest (cattle plague) in 1865. He was a cousin of Jones Quain (1796–1865), the author of *Quain's Elements of Anatomy*, and of Richard Quain, F.R.S. (1800–1887), who was president of the Royal College of Surgeons in 1868, and left £75,000 to University College, London, with which the Quain professorships of botany, English language and literature, law, and physics were endowed. A half-brother of the two last, the Hon. Sir John Richard Quain (1816–1876), was appointed a judge of the Queen's Bench in 1871.

Quakers.—Since 1886 the Society of Friends has increased in numbers and has shown many signs of vigorous life. In constitution there has been little change, save in the position of women, who are now accorded an equal rank with men at all deliberative meetings. The society has been actively interested in questions of peace, slavery, and temperance, and has been ready to express its interest by financial help, as in the case of the Doukhobors. Foreign missionary work has grown apace, and the Home Mission Committee (established 1882, and now consisting of 96 members) is actively engaged in evangelistic labour in England. The Quakers' interest in careful religious education is as strong as ever, and the secular training in their schools is well abreast of modern requirements. In 1895 a conference was held at Manchester, for the discussion of Biblical criticism and kindred topics, and has been followed by "Summer Schools" in theology. On the whole, this period has been one of growing interest in evangelization and in the conditions of modern life and culture.

In 1900 there were in *Great Britain* 17,153 members and 7921 adherents; in *Ireland*, 2609 members; in *U.S.A.*, 93,000 "Friends"; in *Australasia*, about 500; in *Europe*, about 200.

There are 79 *missionaries* (men and women) in India, Syria, China, Ceylon, Madagascar; *members*, 3149; *adherents*, 14,377; *children in schools*, 21,145; *medical patients* treated, 24,299. Madagascar had in 1898 about 400 churches and stations, while India came next with about 23. (G. E. N.)

Quarantine.—The last vestige of the British quarantine law was removed by the Public Health Act, 1896, which repealed the Quarantine Act, 1825 (with dependent clauses of other Acts), and transferred from the Privy Council to the Local Government Board the powers to deal with ships arriving infected with yellow fever or plague, the powers to deal with cholera ships having been already transferred by the Act of 1875. The last incident under the old law was in June 1889, when the s.s. *Neva* arrived at Southampton from Brazil, having had two deaths from yellow fever on the voyage: the ship, crew, and numerous passengers were detained at the Motherbank for six days. There had been no case of a plague ship for many years; but, by a singular coincidence, two or more cases of plague arrived in the Thames (and died in hospital near the docks) in the very weeks of 1896 in which the change to the new system was impending. The great endemic centre of plague in Bombay, which has arisen since 1896, has brought that disease once more to the front as the principal object of quarantine measures. The existing regulations are those of 9th November 1896, issued by the Local Government Board under § 130 of the Public Health Act of 1875 (extended and amended); they apply to yellow fever, plague, and cholera. Officers of the Customs, as well as of Coast Guard and Board of Trade (for signalling), are empowered under Acts of 1889 and 1896 to take the initial steps. They certify in writing the master of a supposed infected ship, and detain the vessel provisionally for not more than twelve hours, giving notice meanwhile to the port sanitary authority. The medical officer of the port boards the ship and examines every person in it. Every person found infected is certified of

the fact, removed to a hospital provided (if his condition allow), and kept under the orders of the medical officer. If the sick cannot be removed, the vessel remains under his orders. Every person suspected (owing to his or her immediate attendance on the sick) may be detained on board forty-eight hours, or removed to the hospital for a like period. All others are free to land on giving the addresses of their destinations to be sent to the respective local authorities, so that the dispersed passengers and crew may be kept individually under observation for a few days. The ship is disinfected, dead bodies buried at sea, infected clothing, bedding, &c., destroyed or disinfected, and bilge-water and water-ballast (subject to exceptions) pumped out at a suitable distance before the ship enters a dock or basin. Mails are subject to no detention. A stricken ship within 3 miles of the shore must fly at the main a yellow and black flag borne quarterly from sunrise to sunset. In 1895 thirty-one vessels arrived infected with cholera at three British ports, from none of which did disease spread ashore. In 1897 a troopship with plague on board arrived at Portsmouth, and landed her 1200 troops according to the above rules without any infection being conveyed by their dispersal.

International Conventions. — Since 1852 eight conferences have been held between delegates of the Powers (see Hygiene), with a view to uniform action in keeping out infection from the East and preventing its spread within Europe; all but the last of these (1897) were occupied with cholera. No result came of the four earlier (Paris 1852, Constantinople 1866, Vienna 1874, and Rome 1885), but each of the subsequent four has been followed by an international convention on the part of nearly one-half of the Powers represented. The general effect has been an abandonment of the high quarantine doctrine of "constructive infection" of a ship as coming from a scheduled port, and an approximation to the principles advocated by Great Britain for many years. The principal States which retain the old system are Spain, Portugal, Turkey, Greece, and Russia (the British possessions Gibraltar, Malta, and Cyprus being under the same influence). The aim of each international sanitary convention has been to bind the Powers to a uniform minimum of preventive action, with further restrictions permissible to individual States. The minimum is now very nearly the same as the British practice, which has been in turn adapted to Continental opinion in the matter of the importation of rags. The Venice convention of 1892 is on cholera by the Suez Canal route; that of Dresden, 1893, on cholera within European countries; that of Paris, 1894, on cholera by the pilgrim traffic; and that of Venice, 1897, on plague from the East, both by the ordinary traffic and by the pilgrim traffic.

The international agreement as it now stands may be summarized as follows:—

General Traffic from the East.—Ships arriving at Suez are classified *indemnes, suspects,* or *infectés,* according as they have had no cases (cholera or plague) on the voyage, or have had such cases, or have such on arrival. All arrivals from an infected port are detained for an examination to be made within forty-eight hours. In practice the difference between *indemne* and *suspect* is not clearly drawn. Ships which have had cases on the voyage enter the Canal "in quarantine," *i.e.*, with guards on board to prevent communication with the shore, and under restrictions as to piloting and coaling; they remain in the state of "quarantine" ten days from the last case (being the incubation period of plague, that of cholera being five days), and may be detained in actual quarantine at Brindisi, Naples, Marseilles, Plymouth, &c., if the ten days have not run out on the voyage thither. Ships with actual cases on board at Suez are treated like suspect ships, after landing their sick and those who had been in immediate attendance on them, the period "in quarantine" counting from the time the sick were put ashore. The crew and passengers of a ship in any of these classes are subject further to a "quarantine of observation" at the port of arrival; but instead of this the British practice of taking the addresses of dispersing passengers and crews is admissible as a minimum, and has been adopted at Marseilles in the case of clean ships from infected ports.

Pilgrim Traffic.—There is now an inspection at the port of departure. Under the convention this should be done among the pilgrims on shore, but it is not usually practicable until they are on board. The cubic space for each pilgrim on the main covered deck is increased to 16 square feet. The ship is to report the state of health on arrival at Aden, where the British Government has provided for the landing of sick pilgrims. Turkey has reduced the period of detention for all pilgrim ships at Camaran to three days, whether infected or not, and has improved the buildings for the reception of parties of pilgrims that must be landed as infected or suspected.

Merchandise.—The return of plague has revived the old doctrine of susceptible articles. Under the Venice convention of 1897 it is forbidden to send from an infected country articles of clothing by parcel post. All other postal matter passes unhindered. There is a schedule of articles which may or may not be prohibited from entering, including old and worn clothing and used bedding (but not if they are the passengers' effects), rags, carpets, sacks, human hair, untanned skins and hides, unmanufactured hair and bristles, wools, claws, hoofs, &c. Most of the signatories have used their option to exclude some or all of these articles. The question arose with Great Britain of excluding wool (a large annual shipment) from Bombay and Kurachee, but it was answered in the negative by the Local Government Board. Where goods are not shut out absolutely they may be subjected to disinfection according to modern methods, which are much more expeditious than the exposures and airings for days or weeks under the old quarantine laws. Much that passes under the name of disinfection is mere formality.

Land Quarantine.—This is abolished for Europe under the convention of 1897. The practice in India since the outbreak of plague in 1896 has been tentative and various as regards railway and other land traffic.

In the United States and the Australian states there has been no recent change. The committee of the U.S. Senate on Public Health and National Quarantine, 1898, while approving the system of the marine hospital service by the several states, considers that infection would be kept out more certainly if the exclusive ultimate control were given to one authority, namely, a federal department. Towards the end of the 19th century a project was discussed of federal quarantine for the Australian continent, with suggested stations at Thursday Island, Albany, Adelaide, and Palmerston.

Literature.—The arguments in support of the British practice were ably restated by the late Sir R. Thorne Thorne in *Report (Medical) of Local Government Board*, xxiv. 1892-93. The same writer reports on the Dresden conference in App. 20 of the *Report*, 1893-94, p. 449. (C. C.)

Quaregnon, a town of Belgium, in the province of Hainaut, 4 miles west of Mons by rail. There are important coal-mines in the vicinity, and foundries, forges, and tobacco factories in the town. Population (1890), 14,361; (1900), 16,033.

Quarrying.—Quarrying is the art of winning or obtaining from the earth's crust the various kinds of stone used in construction, the operation being in most cases conducted in open workings. The term in its primary significance implies the production of material with quadrilateral or rectangular faces, as usually is necessary with building stone, and it is for the extraction of this material that quarrying operations are exclusively conducted. The art was necessarily developed at a remote period of human history; and the immense blocks of stone which may be seen in the early monuments of Egypt show that, in results, the ancient inhabitants of that country achieved great success, though their methods were slow and involved much manual labour. In modern times, and especially in countries where manual labour is costly, machinery has been devised to minimize expense.

According to their composition, building stones are broadly classed as granites, sandstones, limestones, and slates. Under the first of these heads is included a number of crystalline rock species, such as granite, syenite,

gneiss, &c., which to the geologist are quite distinct, but which in commerce are all spoken of as granite. They are chiefly composed of one or more minerals of the feldspar group, mingled with one or more of the micas or with hornblende, and usually contain quartz. Occasionally rocks without quartz, such as diabase, are known commercially as granite. Sandstones are chiefly composed of fragments of quartz cemented into solid rock by silica and oxide of iron. They are always stratified, and in commerce include many varieties, as well as flagstone used for foot-pavements. Limestones consist principally of carbonate of lime, and are usually stratified. Their chief variations are the crystalline form known as marble and the deposit from mineral springs known as Mexican onyx. Slates are mudstones or shales hardened by heat and pressure, and rendered fissile by the latter agent. Chemically they consist chiefly of hydrous silicate of alumina. Gneiss is usually a crystalline rock which, by metamorphism under the influence of heat and pressure, has developed a foliated or schistose structure. Its most manifest character is that the component minerals are arranged in parallel planes or warped surfaces, so that wherever the rock is exposed it presents a striped or banded appearance. Some gneisses are impure sandstones in which, through metamorphism, the mineral fragments have been recrystallized, the stratified arrangement being to some extent retained. These are known as sedimentary gneisses. Many of the gneisses used for building in the United States are foliated granites. Theoretically granites are massive, and have no bedding or stratification, like sandstones and limestones; but actually all rock masses are found to be more or less shattered by the movements of the earth's crust, which occur as a result of its constant readjustment to the cooling and shrinking interior, so that all rocks are divided by cracks or fissures, which are commonly known as joints. In the massive granites these joints, which usually occur in two or more planes at right angles to one another, are of the greatest importance to the quarryman, as they enable him to separate masses of stone with approximately parallel faces. In gneisses the parallel arrangement of the minerals usually coincides with a direction of easy cleavage, known to quarrymen as the "rift"; at right angles to this direction is usually one less easy parting, known as the "grain." Sandstones and limestones are stratified rocks which have been formed as sediments in bodies of water; and whether their beds are found in the normal position of horizontality, or whether they have been tilted and folded by earth movements, the direction of easiest separation is coincident with the original planes of sedimentation and parallel to them. This is therefore called the "rift," while the "grain" is at right angles to it. In gneisses, sandstones, and limestones joints also occur; and while frequently convenient for the division of the beds into masses of useful size, they may be a detriment, as when they occur within the limits of a block available for commercial purposes. In commerce the various kinds of building stone are usually designated by the name of the locality or region in which the quarry is situated. In the case of the more important varieties this geographical name usually conveys to the architect or builder full information concerning the colour, texture, and other properties of the material. For example, the names Hallowell or Quincy granite, Medina or Berea sandstone, and Vermont or Tennessee marble convey in the United States full information to those interested.

Kinds of stone quarried.

The methods of quarrying vary with the composition and hardness of the rocks, their structure, cleavage, and other physical properties; also with the position and character of the deposits or rock-masses. The general purpose of the work is to separate the material from its bed in masses of form and size adapted to the intended use. The work of cutting the stone to accurate dimensions, dressing, rubbing, and polishing are subsequent operations not involved in quarrying. The practice of quarrying consists in uncovering a sufficient surface of the rock by removing superficial soil, sand, or clay, or by sinking a shaft or stope, and then with proper tools and, when necessary, with explosives, detaching blocks of form and size adapted to the purpose in view. Frequently the outer surface of the rock has been affected by the action of the weather and other atmospheric agencies, so that it has become discoloured or softened by decay. The weathered outcrop of a rock is usually a good index of its future behaviour when used as a building stone; for one which yields quickly to the action of the sun, rain, and frost in its original mass, cannot be expected to endure when used in construction, unless it is employed solely for interior work. A quarry should, if possible, be opened on a hillside, for in this case it is usually much easier to dispose of the water which necessarily collects in any deep excavation, and which, if drainage by gravity is not afforded, must be removed by pumping, at considerable expense. As it is generally most convenient to operate on a vertical face of rock, the preliminary work of opening a quarry is usually directed toward the production of this result; but its accomplishment involves the waste of a certain amount of stone, which must be broken into irregular and useless pieces. The separation of blocks of building stone is effected ordinarily by drilling holes along the outlines of the block to be removed, and then, by exploding blasting-powder in the holes, or by driving wedges into them, exerting sufficient force to overcome the cohesion of the rock and rend it asunder. In many quarries it is found most convenient to separate a large mass and afterwards divide it into blocks of the required size. When the rock is stratified, or has an easily determined "rift," the holes are drilled at right angles to the plane of separation. When there is no stratification or "rift," or these natural planes of separation are too far apart, or when the position of the joints is not advantageous, a row of horizontal holes must be drilled into the face or "breast" of the quarry, along which separation is effected by the use of wedges. Again, in thinly-bedded sandstones, where vertical joints are frequent, it is often possible to separate the desired slabs and flagstones with crowbars and wedges, without drilling or the use of explosives. When blasting is necessary, some form of gunpowder is generally used, rather than a violent explosive like dynamite, in order to avoid shattering the rock. This, however, applies only to dimension stone. When the production of broken stone for road-making, concrete, or similar purposes is the sole end in view, violent explosives are preferred. In limestones and marbles and in the softer sandstones, channelling machines, driven by steam, are employed, by which vertical or oblique grooves can be cut with great rapidity to a depth of several feet. A level bed of rock is cleared, and on this are laid rails, along which the machine moves. After the channels are cut, a row of holes is bored perpendicular to the former at the desired distance below the surface of the bed, and by driving wedges into these the required blocks are separated. When the beds of stone to be quarried are thin, and when to remove the whole of the overlying mass of earth or rock would be too expensive, it is found convenient to treat the quarry as if it were a mine, and to rely upon methods similar to those practised in mining. A horizontal bed of rock is usually opened at its outcrop on some hillside. If this is impracticable, a shaft or stope is excavated to reach it; and if dimension

Methods employed.

stone is required, a deep horizontal groove is cut near the top or the bottom of the bed. The quarry face is then divided into blocks by saw-cuts, channels, or rows of drill-holes, and the blocks are separated by wedging or blasting. As the excavation progresses, portions of the rock are left in place as pillars to support the roof. In many localities in Europe where roofing slate is quarried, it is found in beds dipping more or less from the horizontal. These deposits are worked by stopes which follow the inclination of the bed, from which, at convenient intervals, levels are driven across, to take advantage of the cleavage of the slate. As in other subterranean quarries, pillars of rock are left to support the roof, since artificial supports would be more expensive. At some of the marble quarries in Vermont, U.S.A., where the strata are very nearly vertical, the beds are worked to a great depth with a comparatively small surface opening.

HERRMAN. *Steinbruchindustrie und Steinbruchgeologie.* Berlin, 1899. (F. J. H. M.)

Quatrefages de Bréau, Jean Louis Armand de (1810–1892), an eminent French naturalist, whose work ranges over the whole field of zoology from the annelids and other low organisms to the anthropoids and man. Son of a Protestant farmer who had settled in Holland before the Revolution, but returned to France on the outbreak of the war between the two countries, he was born at Berthezène, near Vallerangue (Gard), on 10th February 1810, and died at Paris on 12th January 1892; studied medicine at Strasburg, where he took the double degree of M.D. and D.Sc., one of his theses being a *Théorie d'un Coup de Canon* (November 1829); next year he published a book, *Sur les Aérolithes*, and in 1832 a treatise on *L'extraversion de la Vessie.* Removing to Toulouse, he practised medicine for a short time, without neglecting the natural sciences, and there contributed various memoirs to the local *Journal de Médecine* and to the *Annales des Sciences Naturelles* (1834–36). But being unable to continue his researches in the provinces, he resigned the chair of zoology, to which he had been appointed by the minister, de Salvandy, and in 1839 settled in Paris, where he found in Milne-Edwards a patron and a friend. Elected professor of natural history at the Lycée Napoléon in 1850, he became a member of the Academy of Sciences in 1852, and in 1855 was called to the chair of anthropology and ethnography at the Musée d'Histoire Naturelle. Other distinctions followed rapidly, and continued to the end of his otherwise uneventful career, the more important being honorary member of the Royal Society of London (June 1879), member of the Institute and of the Académie de Médecine, and commander of the Legion of Honour (1881).

De Quatrefages was an indefatigable worker in all branches of his favourite studies, and amid his professional duties and extensive original research he found time to contribute numerous essays to several scientific periodicals, besides some bulky volumes on various branches of zoology and anthropology, between the years 1840 and 1889. Of these, the more important were: *Considérations sur les caractères zoologiques des rongeurs* (1840); "De l'Organisation des animaux sans vertèbres des Côtes de la Manche" (*Annales des Sc. Nat.*, 1844); "Recherches sur le Système nerveux, l'Embryogénie, les Organs des Sens, et la Circulation des Annélides" (*ibid.*, 1844–50); "Sur les Affinités et les Analogies des Lombries et des Sangsues" (*ibid.*); "Sur l'Histoire Naturelle des Tarets" (*ibid.*, 1848–49). Then there is the vast series issued under the general title of "Etudes sur les Types Inférieurs de l'Embranchement des Annelés," and the results of several scientific expeditions to the Atlantic and Mediterranean coastlands, Italy, and Sicily, forming a series of articles in the *Revue des Deux Mondes*, or embodied in the *Souvenirs d'un Naturaliste*, 2 vols. (1854). These were followed in quick succession by the *Physiologie Comparée*, *Metamorphose de l'Homme et des Animaux* (1862); *Les Polynésiens et leurs Migrations* (1866); *Histoire Naturelle des Annelés Marins et de l'eau douce*, 2 vols. (1866); *La Rochelle et ses Environs* (1866); *Rapport sur les Progrès de l'Anthropologie* (1867); *Ch. Darwin et ses Précurseurs français* (1870), a study of evolution in which the writer takes somewhat the same attitude as A. R. Wallace, combating the Darwinian doctrine in its application to man; *La Race Prusienne* (1871); *Crania Ethnica*, jointly with Dr Hamy, 2 vols., with 100 plates (1875–82), a classical work based on French and foreign anthropological data, analogous to the *Crania Britannica* of Thurnam and Davis, and to Morton's *Crania Americana* and *Crania Ægyptiaca*; *L'Espèce Humaine* (1877); *Nouvelles Études sur la Distribution Géographique des Négritos* (1882); *Hommes Fossiles et Hommes Sauvages* (1884); *Histoire Générale des Races Humaines*, 2 vols. (1886–89), the first volume being introductory, while the second attempts a complete classification of mankind.

De Quatrefages was an accurate observer and unwearied collector of zoological materials, gifted with remarkable descriptive power, and possessed of a clear, vigorous style, but somewhat deficient in deep philosophic insight. Hence his serious studies on the anatomical characters of the lower and higher organisms, man included, will retain their value, while many of his theories and generalizations, especially in the department of ethnology, are already forgotten. Even his fellow-worker, Dr Hamy, has given up the view that the cradle of mankind is to be sought in the Arctic regions; and the astonishing expansion given to the primitive Negrito peoples and to the Norse element in North America are no longer taken seriously. Indeed, his whole scheme of classification must be regarded as a failure, and has not been accepted by any leading systematist. (A. H. K.)

Quebec, a province of Canada, bounded on the E. by Labrador and the Gulf of St Lawrence; on the S. by Chaleur Bay, New Brunswick, and the United States; on the S.W. and W. by the Ottawa river and Ontario; and on the N. by Ungava district.

Rivers.—The principal river is the St Lawrence, which flows through the entire length of the province. Its largest tributary—the Ottawa—730 miles long, forms the boundary between Ontario and Quebec from the head of Lake Temiskaming to Point Fortune, and receives several large branches from the Quebec side. There are many affluents of the St Lawrence from the right bank. The Cape Chat, Ste Anne (de Monts), Magdalen, and York fall into the Gulf of St Lawrence; the Bonaventure, Cascapedia, Matapedia, and Patapedia, into Chaleur Bay; and the Peribonka, 280 miles, Mistassini, 225 miles, Ashwapmuchuan, Ouiatchuan, and Metabetchouan, into Lake St John. North of the Height-of-Land, the Harricanaw, Nottaway, 450 miles long, with its tributaries the Megiskun, Waswanipi, and Broadback, the Rupert, 260 miles, and East Main, 420 miles, discharge their waters into James Bay, and the Hamilton, 630 miles long, with its southern affluents the Ashuanipi, Attikonak, and Kenamou, into Hamilton inlet.

Lakes.—The principal lakes south of the St Lawrence are Champlain, Memphremagog, Megantic, Temiscouata, and Matapedia; between the St Lawrence and the Height-of-Land, Temiskaming, Des Quinze, Expanse, Victoria, Dumoine, Kippewa, Kakabonga, Thirtyone-miles, Whitefish, Piscatong, Simon, Nomining, Nemikachi, Kempt, St John, Pipmaukin, Manuan, Pletipi, Ishimanikuagan; north of the Height-of-Land, Mistassini, 98 miles long and 10 wide and at an elevation of 1350 feet above the sea, Abitibi, Mattagami, Waswanipi, Chibougamau, Obatagamau, Ashuanipi, Attikonak, Menihek, Dyke, and Ossokmanuan.

Climate.—The climate varies from the cold but bracing winters and the long warm summers of the St Lawrence and Ottawa valleys, to the long cold winters and short cool summers of the portion to the north of the Height-of-Land. The following table gives the average temperature and precipitation at a number of places in the southern portion of the province :—

	Latitude.	Longitude.	Altitude.	Mean Temperature.			Precipitation.
				Summer.	Winter.	Year.	
			ft.	°	°	°	in.
Anticosti, W. pt.	49° 52′	64° 32′	15	55·4	12·9	36·9	41·32
Bird Rocks .	47° 51′	61° 08′	106	57·2	18·4	...	27·51
Chicoutimi .	48° 25′	71° 05′	159	58·0	9·8	36·5	30·33
Quebec . .	46° 48′	71° 13′	315	61·6	14·6	38·7	42·96
Cranbourne .	46° 20′	70° 43′	...	58·2	12·6	...	46·77
Montreal . .	45° 30′	73° 35′	187	64·8	17·1	42·3	40·20

The normal percentage of bright sunshine at Montreal is 46, a higher average than northern Europe.

Area and Population.—The original area included within the limits of the province—228,900 square miles—has been increased to 339,360 square miles by the extension of the northern boundary. By Order in Council of 8th July 1896 the boundary-line is traced from the intersection of the then western boundary—produced due north—with the shores of James Bay, along the shores of the bay to the mouth of the East Main river, thence by this river to its source in Patamisk Lake in approximate 52° 55′ N. and 70° 42′ W., thence by a due east line to the Ashuanipi river, and thence by the Ashuanipi and Hamilton rivers and the undefined western boundary of Labrador to the point of intersection of a meridian line from Anse au Sablon with the 52nd parallel. The population (1881) was 1,359,027; (1891), 1,488,535; (1901), 1,648,898 (824,454 males and 824,444 females), or 4·9 per square mile. The urban population increased from 19·5 per cent. in 1871 to 22·8 per cent. in 1881 ; to 29·2 per cent. in 1891 ; and to 39·8 per cent. in 1901. In 1891 there were 212,094 engaged in agricultural pursuits ; mining, 1534 ; fishermen, 3433 ; trade and transportation, 50,588 ; manufacturing and mechanical pursuits, 93,206 ; domestic and personal services, 73,307 ; professional avocations, 16,342 ; and in the non-productive class, 26,396. The chief towns are : Quebec, the capital, population, 68,840 in 1901 ; Montreal, the commercial metropolis of Canada, 267,730 (1901) ; St Henri, 21,192 ; Hull, 13,993 (1901) ; Sherbrooke, 11,765 (1901) ; St Hyacinthe, 9210 ; Three Rivers, 9981 ; Valleyfield, 11,055 ; St Louis de Mile End, 10,933 ; St Cunegonde, 10,912 ; Westmount, 8856 ; Sorel, 7057 ; Levis, 7783 ; Lachine, 5561 ; St Johns, 4030 ; St Jerome, 4132 ; Fraserville, 4569 ; Joliette, 4220 ; Lauzon, 3416 ; and Maisonneuve, 3958.

The following table shows the birth-places of the inhabitants of the province in 1901 :— Canada, 1,560,190 ; England, 20,726 ; Ireland, 14,275 ; Scotland, 7338 ; other British possessions, 2907 : total, 1,605,436. United States, 28,405 ; France, 3181 ; Germany, 1543 ; Russia and Poland, 2670 ; other foreign countries, 7663 : total foreign countries, 43,462. There were 9123 Indians in the province in 1901, as compared with 11,649 in 1892.

Vital Statistics.—The table below gives vital statistics of the province for the period 1871–1900 :—

	1871.	1881.	1891.	1900.
Births . . .	46,286	53,013	55,811	53,815
Deaths . . .	20,873	25,930	28,154	32,778
Marriages . . .	Statistics not collected.			10,103
Still-born, number .	,,	,,	,,	1,606
,, ,, percentage	,,	,,	,,	4·9%

Administration.—The affairs of the province are administered by a lieutenant-governor and an executive council of seven members, with portfolios, the latter being responsible to the Legislative Assembly, which consists of seventy-four members, and to the Legislative Council of twenty-four councillors.

Religion.—The Roman Catholic Church, the adherents of which form 86·7 per cent. of the population, has nine dioceses, namely, the archbishoprics of Quebec and Montreal, and the bishoprics of St Hyacinthe, Sherbrooke, Valleyfield, Chicoutimi, Nicolet, Rimouski, and Three Rivers. The Church of England has two dioceses, namely, Montreal and Quebec. In 1891 the religious denominations were as follows :— Roman Catholics, 1,429,260 ; Church of England, 81,563 ; Presbyterians, 58,013 ; Methodists, 42,014 ; Baptists, 8480 ; Congregationalists, 5173 ; Adventists, 3079 ; Jews, 7498 ; other denominations, 11,692 ; not specified, 2126.

Education.—In 1901 the Roman Catholic committee controlled 4322 elementary schools, 511 model schools, 139 academies, 2 normal schools, 19 classical colleges, 1 university—Laval, in Quebec, with a teaching branch at Montreal—and 3 schools for deaf-mutes and the blind. The Protestant committee controlled 876 elementary schools, 46 model schools, 29 academies, 1 normal school, 3 colleges, 2 universities—McGill, in Montreal, and Bishops College, Lennoxville—and a school for deaf-mutes and the blind. In addition, there were 7 schools of arts and manufactures and 4 of agriculture and dairy-farming. The number of pupils in the Roman Catholic elementary schools was 174,613, and average attendance 119,884 ; in Protestant elementary schools, 26,511 pupils and average attendance, 18,903 ; pupils in schools of all kinds, 326,507. There were 1344 school municipalities ; 5595 schoolhouses ; 7087 lay teachers (791 men and 6296 women) ; 4285 teachers in religious orders (1535 males and 2748 nuns). The local contributions amounted to $2,999,804, supplemented by a Government grant of $241,948 ; total, $3,241,752.

Finance.—The principal sources of revenue are the subsidy from the Dominion Government and moneys received from the sale of timber limits, fees for liquor licences, &c. The principal items of revenue and expenditure for the year ending 30th June 1901 were as follows :—

Revenue.		Expenditure	
Dominion subsidies .	$1,278,987	Interest on debt .	$1,436,510
Woods and forests .	1,471,004	Justice, administration	531,648
Liquor licences .	661,968	Charities and asylums	389,571
Succession duties .	163,511	Education . .	451,590
Law stamps . .	187,724	Civil government .	278,307
Miscellaneous . .	800,238	Miscellaneous . .	1,428,632
Total revenue .	$4,563,432	Total expenditure	$4,516,258

The gross debt in 1901 was $36,146,873, of which $2,549,214 has been assumed by the Dominion ; other assets, not including public buildings, aggregate $11,364,132, leaving a net debt of $22,233,527.

Minerals and Mining.—Gold-washing has been carried on in a desultory manner on the Chaudière river and its tributaries for upwards of sixty years, but the total product only amounts to about $2,000,000. Copper is obtained as a by-product from the pyrites mined in the Capelton district for the production of sulphuric acid. Copper ore has been mined at a number of places in the south-eastern portion of the province, notably at the Harvey Hill and Acton mines. Iron was mined as far back as the latter part of the 17th century. Magnetite and hæmatite, bog and titanic iron ores are found at many points throughout the province. The production of apatite (phosphate), which in 1891 amounted to 26,591 tons, has dwindled to a few tons. Asbestos of excellent quality is mined in the Thetford, Coleraine, and Danville districts. The total value of the mineral production for 1901 was $3,640,000, copper and asbestos being the most important.

Agriculture.—General agricultural instruction is given at agricultural schools at Oka, Notre Dame du Lac, Compton, and Ste Anne de la Pocatiere ; and there is also a housekeeping school for farmers' daughters at Roberval. Two veterinary schools, attached to McGill and Laval universities respectively, and eleven societies for the improvement of horticulture, receive grants. Subventions are given to the dairy association for the inspection of butter and cheese factories, and to the St Hyacinthe dairy school. There were 452 creameries and 1841 cheese factories in the province in 1901. In 1891 the total acreage occupied was 15,961,763 acres ; improved, 8,670,946 acres ; under crop, 5,542,780 ; in pasture, 3,054,539 ; gardens and orchards, 73,627 ; and woodland and forest, 7,290,817. There were 174,996 occupiers of lands, of whom 154,227 were proprietors, 19,479 tenants, and 1290 employés. In 1899 the total acreage assessed was 17,110,770 ; value of taxable real estate, $274,719,408 ; value of non-taxable real estate, $37,390,957.

The following are statistics of live stock in the province in 1891 :—Horses, 345,789 ; working oxen, 49,608 ; milch cows, 546,986 ; sheep, 722,025 ; swine, 348,397.

Fisheries.—The fisheries yielded in 1881 a product valued at $2,751,962 ; 1891, $2,008,679 ; 1900, $1,989,279 ; and in the latter year gave employment to 13,097 men, in 29 vessels and 1483 boats ; capital invested in boats, nets, &c., $830,869 ; fish exported, $515,427. The value of the lobster catch in 1900 was $204,821.

Manufactures.—The following table gives statistics of the principal manufacturing industries of the province for the year 1891 :—

	Number of Factories.	Number of Employés.	Value of Product.
Saw-mills . .	1815	13,241	$10,082,891
Leather manufactures	2270	11,863	12,533,551
Flour and grist mills	871	1,628	8,697,483
Tanneries . . .	354	1,956	5,815,532
Foundries . .	161	4,107	5,755,124
Cotton mills . .	6	3,792	3,656,170

There were 23,037 industrial establishments, with a total fixed capital of $58,449,404; working capital, $59,841,711; hands employed, 117,389; wages per annum, $30,699,115; raw material used, $85,630,496; and a total product valued at $153,255,583.

Exports and Imports.—The following table gives statistics of exports and imports for the period 1879–99:—

	Exports.	Imports.	Duty.
1879 . . .	$29,740,512	$30,924,842	$4,733,249
1889 . . .	37,223,605	49,272,475	10,408,008
1899 . . .	70,311,571	72,230,739	10,002,839

On 1st January 1902 there were 1265 vessels, with a tonnage of 142,664 tons, on the registry books of the province.

Railways.—In 1901 the total length of the steam railways in the province was 3544 miles, 19·4 per cent. of the railway mileage of the Dominion. The principal railway systems in Quebec are the Canadian Pacific, 1017 miles; Grand Trunk, 446; Intercolonial, 452; and Quebec and Lake St John, 241. There are 206 miles of electric railways in the province, principally in Montreal and Quebec. (J. WH*.)

Quebec, the capital of the province of the same name and the third city of Canada, situated on the north bank of the river St Lawrence, in 71° 12′ 19″·5 W. and 46° 48′ 17″·3 N. It is the terminus of the Great Northern, Quebec and Lake St John, Quebec, Montmorency, and Charlevoix, and Canadian Pacific railways; and the projected bridge to Lévis, on the south shore, will also admit the Intercolonial, Grand Trunk, and Quebec Central railways. The harbour is spacious and capable of accommodating ships of the largest tonnage, and, with the Louise basin and Lorne graving-dock—the latter on the opposite shore at Lévis—forms one of the best harbours in America. The Louise basin consists of twin wet-docks and tidal harbours, with areas of 40 and 20 acres respectively, and a minimum depth of 26 feet. The Parliament and departmental building, completed in 1887 at a cost of nearly $2,000,000, is one of the finest buildings in Canada. It forms a perfect square, each side of which is 300 feet in length, with towers at each angle: statues of Wolfe, Montcalm, Frontenac, de Salaberry, de Lévis, Lord Elgin, and other prominent actors in Quebec history occupy recesses in the front façade. It contains an excellent library, and in its vaults are nearly all the original archives of New France prior to the conquest in 1760. The new city hall is a fine building in the Norman style of architecture, and accommodates, in addition to the mayor and civic officials, the recorder's court and central fire and police station. An electric railway affords rapid communication with all parts of the city and vicinity. The total tonnage of shipping entered inwards during the year 1900–01 was 1,326,987 tons; exports, $5,055,336; imports, $6,324,991. Population (1891), 63,090; (1901), 68,840. (J. WH*.)

Quedlinburg, a town of Prussia, province of Saxony, at the north foot of the Harz Mountains, 12 miles by rail south-east of Halberstadt. The municipal museum contains collections of bronze and iron objects, urns, arms, &c. Here is a monument of the war of 1870–71 (1895), also an allegorical group of peace (1898). Ritter, the geographer (1779–1859), was born in Quedlinburg. The abbey church was in part rebuilt in 1882. The town is famous for its nurseries and seed farms. Population (1885), 19,323; (1900), 23,378.

Queenborough, a municipal borough and parish in the Faversham parliamentary division of Kent, England, on the Isle of Sheppey, 2 miles south of Sheerness. On the site of the present town stood a town-castle and free borough which Edward III. named Queenborough in honour of his consort, Philippa of Hainault. Before the Reform Act (1832) the town returned two members to Parliament for a population of 786. By that Act it was disfranchised. In 1890 Portland cement works were built, and there is a large trade in timber. The South-Eastern and Chatham Railway Company have laid down a branch line for their Continental traffic *viâ* Flushing. Continental mails leave twice daily. Population of municipal borough (1901), 1546.

Queen Charlotte Islands.—This compact group lies off the northern part of the coast of British Columbia, and forms part of that province of Canada. It occupies a position similar to that held by Vancouver Island, farther to the south, in regard to the mainland coast and its immediately adjacent islands, but is separated by a somewhat wider sea from that coast. Although the islands promise to become important in the future, because of their excellent harbours, the discovery of good seams of bituminous coal (besides the anthracite already known), their abundant timber of certain kinds, and their prolific fisheries, but little settlement or occupation has as yet taken place. The wonderfully productive halibut fisheries of Hecate Strait, separating these islands from the mainland and its adjacent islands, have attracted the attention of fishing companies, and great quantities of this fish are being taken regularly and shipped across the continent in cold storage. The natives, the Haida people, constituted with little doubt the finest race, and that most advanced in the arts, of the entire west coast of North America. They had developed in its highest degree the peculiar conventional art of the north-west coast Indians, which is found in decreasing importance among the Tshimpsians on the west, the Thlinkeets to the north, and the Kwakiools and other tribes farther south on the Pacific seaboard. The carved totem-posts of the Haida, standing in front of the heavily-framed houses, or at a little distance from them, and constituting mortuary posts upon which the dead were placed, generally exhibited designs treated in a bold and original manner, highly conventionalized, but always recognizable in their purport by any one familiar with the distinctive marks of the animal forms portrayed. These primitive monuments are now, however, rapidly falling to decay, and the people who erected them are becoming reduced in number and spirit. Native population of the islands, less than 700.

Queen's County, an inland county of Ireland, province of Leinster.

Population.—The area of the administrative county in 1900 was 424,690 acres, of which 127,305 were tillage, 228,397 pasture, 147 fallow, 10,685 plantation, 18,914 turf bog, 4338 marsh, 17,009 barren mountain, and 17,895 water, roads, fences, &c. The new administrative county under the Local Government (Ireland) Act, 1898, does not include the portion of the town of Carlow formerly situated in Queen's County. The population in 1881 was 73,124, in 1891, 64,883, and in 1901, 57,226, of whom 29,523 were males and 27,703 females, divided as follows among the different religions:—Roman Catholics, 50,461; Protestant Episcopalians, 5946; Presbyterians, 274; Methodists, 411; and other denominations, 134. The decrease of population between 1881 and 1891 was 11·27 per cent., and between 1891 and 1901 10·4 per cent. In 1891 the average number of persons to an acre was ·15, and of the total population, 57,142 persons inhabited the rural districts, being an average of 104 persons to each square mile under crops and pasture. The following table gives the degree of education in 1891:—

	Males.	Females.	Total.	Percentage.			
				R. C.	Pr. Ep.	Pres.	Meth.
Read and write	22,463	21,775	44,238	72·5	91·1	92·0	94·3
Read only .	3,193	3,409	6,602	12·1	4·6	2·3	2·2
Illiterate .	4,552	3,755	8,307	15·4	4·3	5·7	3·5

The percentage of illiterates among Roman Catholics in 1881 was 22·4. In 1891 there were 10 superior schools, with 360 pupils (Roman Catholics 259 and Protestants 101), and 135 primary schools, with 8811 pupils (Roman Catholics 7648 and Protestants 1163). The number of pupils on the rolls of the National schools on 31st December 1900 was 8825, of whom 7817 were Roman Catholics and 1008 Protestants. The following table gives the number of births, deaths, and marriages in the years specified :—

	Births.	Deaths.	Marriages.
1881 . .	1327	966	219
1891 . .	1311	1024	232
1900 . .	1119	1077	221

In 1900 the birth-rate per 1000 was 9·6, and the death-rate 8·8; the rate of illegitimacy was 1·9 per cent. of the total births. The total number of emigrants who left the county between 1st May 1887 and 31st December 1900 was 56,641, of whom 28,380 were males and 28,261 females. The chief towns in the county, with their populations in 1901, are Maryborough, 2953; Mountmellick, 2751; Mountrath, 1304.

Administration.—The county is divided into two parliamentary divisions, Leix and Ossory, the number of registered electors in 1901 being respectively 6553 and 6613. The rateable value in 1900 was £257,111. By the Local Government (Ireland) Act, 1898, the fiscal and administrative duties of the grand jury were transferred to a county council, urban and rural district councils were established, and under that Act the county now comprises 2 urban and 5 rural sanitary districts.

Agriculture.—The following tables show the acreage under crops, including meadow and clover, and the amount of live stock in 1881, 1891, 1895, and 1900. The figures for 1900 are for the new administrative county.

	Wheat.	Oats.	Barley, Rye, Beans, &c.	Potatoes.	Turnips.	Other Green Crops.	Meadow and Clover.	Total.
1881 .	4419	23,614	21,402	16,656	11,745	3497	58,498	130,831
1891 .	618	21,566	22,592	15,162	12,412	3257	55,941	131,548
1895 .	23	22,670	20,525	14,033	12,496	3188	61,102	134,037
1900 .	206	21,487	19,708	13,189	12,016	3634	57,065	127,305

In 1900 the total value of the cereal and other crops was estimated at £728,912. The number of acres under pasture in 1881 was 212,281; in 1891, 222,241; and in 1900, 227,305.

	Horses & Mules.	Asses.	Cattle.	Sheep.	Pigs.	Goats.	Poultry.
1881 .	14,824	5533	74,277	74,344	28,021	5162	256,324
1891 .	15,624	6318	86,184	95,095	34,350	6250	288,369
1895 .	17,151	5961	79,590	69,685	31,320	5014	287,893
1900 .	14,400	5913	84,420	74,182	30,053	4577	325,444

The number of milch cows in 1891 was 21,156, and in 1900, 19,888. It was estimated that the total value of cattle, sheep, and pigs for 1900 was £1,266,949. In 1900 the number of holdings not exceeding 1 acre was 1695; between 1 and 5, 1600; between 5 and 15, 2238; between 15 and 30, 2004; between 30 and 50, 1322; between 50 and 100, 1213; between 100 and 200, 600; between 200 and 500, 257; and above 500, 36: total, 10,965. The number of loans issued (the number being the same as that of tenants) under the Land Purchase Acts, 1885, 1891, and 1896, up to 31st March 1901, was 1126, amounting to £526,031. The number of loans for agricultural improvements sanctioned under section 31 of the Land Act, 1881, between 1882 and 1901, was 188, and the amount issued was £14,193. The total amount issued on loan for all classes of works under the Land Improvement Acts, from the commencement of operations in 1847 to 31st March 1901, was £164,473.

QUEENSLAND.

I. Physical Characteristics and Statistics.

QUEENSLAND, originally a British colony, and now a state of the Australian Commonwealth, occupies the whole of the north-eastern portion of the Australian continent, and comprises also the islands in Torres Strait. It lies between 10° and 29° S., and is bounded on the N. by Torres Strait, on the N.W. by the Gulf of Carpentaria, on the W. by the Northern Territory of South Australia, on the S. by New South Wales, and on the E. by the Pacific Ocean and Coral Sea. It has an area of 668,497 square miles, a coast-line of 2500 miles, is 1250 miles long, and 950 miles wide at its widest part.

Climate.—The rainfall varies greatly in different parts, Geraldton on the Johnstone river standing first with an average of 150 inches for the year, Brisbane totalling 51 inches. The smallest occurs in the extreme west, with an average at Winton of 18 inches and at Birdsville of 6 inches. Rain usually falls from December to March, the monsoons producing a wet season during these months with great regularity in the north, and irregularly throughout the rest of the year, according to locality. The central, say from south of Mackay to north of Bundaberg, is drier than the north, whilst from Bundaberg southwards the rainfall is precipitated at more regular intervals throughout the year. West of the coast range the rainfall diminishes rapidly and droughts are frequent; the absence of dew in the western country allows the sun's heat to convert the native grasses into hay, their nutritive qualities being preserved long after all sign of moisture has left. Sheep and cattle live and keep their condition on such food, provided they get abundance of water. The fertility of the soil is such that two or three good thunderstorms will provide abundance of green grass in a few days. The heaviest losses in stock occur after bush fires have swept off the dry grass. The summer heat is not greater in North Queensland than in the south, but is more constant and lasts longer. West of the coast range the air is dry and hot, and the thermometer rises to 106°; east of that it rarely exceeds 96° in the shade. The monsoons play an important part in cooling the atmosphere near the coast, and are very regular in the north. The winter climate is perfection, especially in the north, but frosts are frequent and regular west of the coast range. Ice is commonly seen at Herberton, 17° S., during winter, and the surrounding highlands are looked upon as the sanatorium of the north. On the Darling Downs frosts are of nightly occurrence. The heat is oppressive during the rains of summer, but manual labour is carried on by miners, timber-getters, stockmen, and labourers of all classes in every part throughout the whole day. Adelaide, Melbourne, and Sydney often show higher temperatures than even the north, and frequently suffer from hot winds, which are almost unknown in Queensland. The diseases which cause the greatest number of deaths are miasmatic, constitutional, digestive, and respiratory, in the order named, the death-rate for the state for 1900 being 11·72 per 1000 inhabitants. The deaths from phthisis are steadily decreasing, and a large sanatorium has been erected at Dalby for the treatment of consumptives, the air there being peculiarly beneficial to such patients. The following are the death-rates per 1000 inhabitants of the principal cities of Australia :—Brisbane, 12·00; Sydney, 12·74; Adelaide, 15·20; Perth, 16·36; Hobart, 14·03; Melbourne, 15·39.

Geology.—Queensland may be divided geologically into two great portions, occupying nearly equal areas, and possessing very different physical features. The one extends along the eastern coast from the New South Wales border northwards to the 12th parallel of latitude, with an average width of about 200 miles from east to west. This division also comprises a large area in the north-west portion of the state. In this district occur the loftiest mountain ranges, the remnants of what was once a high tableland. The rainfall is comparatively large, and the country is well watered and timbered, and in places where the soil is good it is covered with dense scrubs. The drainage is eastwards into the Pacific Ocean. This region contains stratified rocks of different ages from the oldest Palæozoic, the exact relation of the older of which has not yet been determined, up to those of recent origin. There are also granites, porphyries, and syenites, partly of plutonic and partly of metamorphic origin, as well as other intrusive and interbedded igneous rocks. It is in this division that most of the mineral wealth exists. The other large area is what is known as the Western Interior, consisting almost entirely of the Lower Cretaceous rocks, known as the Rolling Downs formation, overlaid unconformably in places by the Desert Sandstone. This presents a vast area of almost treeless plains, though here and there dense Gidia scrubs exist. The rainfall over this area, more especially in the south-western districts, is very small, and consequently the

river beds are generally dry. The want of water renders it impossible to stock to anything like its full extent some of the very best pastoral land in the state. But this difficulty has been largely overcome in recent years by the tapping of the vast supplies of artesian water contained in these beds. The rivers north of the high open downs about 21° 50′ S. flow north into the Gulf of Carpentaria, while to the south they flow southwards towards the Great Australian Bight.

In the *Palæozoic* rocks many of the most important gold, silver, tin, and copper fields are situated, amongst which may be mentioned the Croydon, Etheridge, Eidsvold, Charters Towers, and Cape River goldfields; Kangaroo Hills and Running Creek silver and tin fields; the Herberton, Annan, and Bloomfield tin fields; and the Chillagoe, Mount Perry, and Peak Downs copper fields.

Silurian rocks extend westwards from Cloncurry to the western border, southwards to below Boulia, and right away to the extreme north-west, with the exception of a mass of strata north and east of Camooweal mapped as Devonian (?). In this area are situated the Cloncurry, M'Kinlay, and Leichhardt goldfields; the Cloncurry and Lawn Hill copper fields; and the rich ironstone deposits of Mount Leviathan and other hills in the neighbourhood of Cloncurry.

The principal area of *Middle Devonian* is in the Upper Burdekin, including the Fanning river, Burdekin Downs, and Broken river. Rocks of this age also occur at Chillagoe; Reid's Gap on the Townsville–Charters Towers Railway; south of Clermont; and at Raglan, and in the neighbourhood of Olsen's Caves, north of Rockhampton. The argentine silver field occurs in a series of slates and schists, &c., supposed to belong to this formation.

The *Permo-Carboniferous* system includes five formations, namely, the Gympie, Star, and the Lower, Middle, and Upper Bowen formations. The Gympie formation occupies large areas in the south-eastern and north-eastern portions of the state, and consists of sandstones, grits, conglomerates, shales, and slates, which in parts have undergone considerable alteration, together with bedded volcanic rocks. Interbedded volcanic rocks are especially numerous in the type district. The rocks generally dip at a high angle of inclination. They contain a very scant flora represented by *Calamites*, *Lepidodendron*, and fossil wood; but they have produced the largest fauna of any Queensland rocks. Numerous gold and mineral fields occur in this formation, amongst which may be mentioned:—*Goldfields*, Gympie, Cania, Raglan, and Calliope, and other smaller fields in the Gladstone district, the Rockhampton fields, the Warwick fields, Mount Shamrock, and Mount Biggenden, Eidsvold, Paradise, the Hodgkinson, Mulgrave, Palmer, and Nebo. *Silver*, Montalbion, Chillagoe, Dry river, and Sellheim fields. *Copper*, the Mount Coora mine, Gigoomgan, and Tebar copper mines. *Mercury*, the Kilkivan mines. *Bismuth*, Mount Biggenden and Mount Shamrock. *Antimony*, the Northcote, Mitchell mines. *Tin*, the Cannibal Creek tin mines. *Cobalt*, Mount Coora mine.

There is but little Palæontological evidence for separating the Star beds from the Gympie series. They contain nineteen species peculiar to themselves, and twelve species common to the Gympie beds. They are, however, generally less highly inclined than the latter, and have not been so much disturbed and altered. They are best developed at the following places:—Near the junction of the Great and Little Star rivers, from which they take their name; near Dotswood, Keelbottom Creek; in the neighbourhood of Harvest Home, Lornesleigh, and Mount M'Connell stations, on the latter of which the nearly complete remains of a fish of the genus Palæoniscus was found; and lastly, a large area of these beds exists in the neighbourhood of Drummond's range on the Central Railway, where numerous remains of the teeth and scales of fish have been discovered. The Lower Bowen formation consists of a series of white and yellow sandstones, with beds of conglomerate containing pebbles of quartzite porphyry, the latter being derived from the metamorphic rocks in the vicinity. The lowest beds of this formation consists of volcanic agglomerate seen near the heads of Pelican Creek, south-west of Bowen. This series dips under the bedded trappean rocks of Mount Toussaist. Another area of these rocks occurs north of Mackay. They have here undergone considerable alteration. So far no fossiliferous remains have been found in this formation. The Middle Bowen consists chiefly of alternate white and yellow sandstones, blue and grey shales, and impure arenaceous ironstones. Two seams of coal, known as the Kennedy and Garrick seams, have been met with near Pelican Creek in this series. The Middle Bowen series is mainly marine, although it contains in parts a land flora. Seams of coal occur on the Dawson river both north and south of the railway line, and quite recently a seam of very good coal, 9 feet thick, perhaps the best in Queensland, has been discovered on the Dawson river, about 30 miles south of the Central Railway. The Upper Bowen beds are chiefly fresh-water, and possess but a small flora and fauna. They contain numerous seams of coal, including the Macarthur, Daintree, and Havilah seams, but most of the seams have been destroyed through being burnt by intrusive sheets of dolerite. Beds of this formation occur west of Laura, the terminus of the Cooktown Railway, on the Little river coalfield; at Hamilton, about 20 miles west of Cooktown; at Stewart's Creek, near Townsville; also farther south near Mackay; on the Isaac and Dawson rivers at Dinner Creek near Stanwell, on the Central Railway; and at Blair Athol, about 10 miles north-west of Clermont. Blair Athol is the only place where coal seams in this formation are being actually worked. The coal is one of the best steam coals worked in the state.

The Burrum coal-field is the lowest member of the *Mesozoic* rocks (Lower Trias-Jura), and it extends along the coast from north of Bundaberg down to south of Noosa Heads, occupying an area of about 3000 square miles. The Coal Measures over a large portion of this area are covered with thin sandstones and conglomerates of more recent origin, and to this fact the flat and barren nature of the country is due. The formation consists of white and brown sandstones and grey and black shales. Seams of coal are known to occur from Littabella Creek in the north to near Noosa in the southern portion of the field. The seams have been worked chiefly in the neighbourhood of the Burrum river, near the townships of Howard and Torbanlea, about 28 and 15 miles respectively north-north-west of Maryborough. In the Burrum river above the railway bridge at least five seams of workable thickness can be seen cropping out in the bank within half a mile, and having a regular dip to the north-east at about 12 degrees. The two principal collieries are the Queensland Coal Company's and the Torbanlea. The Burrum is the second largest coal-producing field in the state. The Ipswich coal-field (Upper Trias-Jura) covers an area of about 12,000 square miles in the south-east. In the neighbourhood of Brisbane the base of the Measures is an ash or ashy sandstone, consisting of a felspathic matrix with blebs of quartz and pebbles of schist and quartz, &c. The formation consists of the usual alternating sandstones, shales, and conglomerates. The Coal Measures to the west of this area at Jimbour and Clifton, &c., are on a higher horizon than those in the Ipswich district, from which they are separated by a thick layer of basalt. The Ipswich coal-field has the largest output of any. Several coal seams occur in the Albert and Logan district, and thin coal has been met with in the Brisbane district. The seams that are being worked occur in the Ipswich basin and near Clifton. In the Ipswich area at least sixteen distinct seams either have been or are being worked.

In 1894 Mr R. L. Jack and Mr Gibb Maitland made a survey of the eastern edge of the Lower Cretaceous (Rolling Downs) formation, which was followed along on the western side of the Main Dividing Range, with the result that a porous sandstone, which has been named the Blythesdale Braystone, the chief intake rock of the series, was traced near the base from the neighbourhood of Texas on the southern border to Normanton in the north. The amount of water yielded by the numerous bores is almost infinitesimal when compared with the amount of water taken in by this rock and other porous beds, and the only conclusion to be arrived at is that the water finds its way into the sea at the Great Australian Bight and in the Gulf of Carpentaria. The total number of bores known to the end of June 1899 is 715, and the total continuous yield from 440 of these is 266,377,056 gallons per day. The Rolling Downs formation has been classified under the general term of Cretaceous, but it contains amongst its numerous fauna forms allied to Oolitic.

The Upper Cretaceous (Desert Sandstone) formation at one time covered the greater portion of Queensland, but the work of denudation has left only isolated patches or outliers, which in the western districts overlie unconformably the Rolling Downs beds. Some of these areas are of large extent, especially those in the centre, where they hide the outcrop of the Blythesdale Braystone. The base of the Desert Sandstone is from 1000 to 1800 feet above sea-level in the southern and central portions of the state, but in the Cape York Peninsula it is nearly at sea-level. The Desert Sandstone consists of coarse and horizontal sandstones, shales, magnesite shales, and conglomerates, &c. The conglomerates contain pebbles of quartz, and others derived from the rocks in the vicinity. A series of rocks in the neighbourhood of Maryborough, which overlie the Burrum Coal Measures, against which they are faulted, have been provisionally included in this formation. They have produced a large number of fossils, some of which are allied to those from the Desert Sandstone at Croydon.

The *Tertiary* deposits are very poorly represented; in fact, with the exception of a few old alluvial drifts, no sedimentary Tertiary deposits have been described. There was undoubtedly great volcanic activity in Tertiary times, as is evidenced in numerous parts of the state by the outflows of basalt capping rocks of Desert Sandstone age. The Post-Tertiary and Recent period is represented by bone drifts on the Darling Downs and Peak Downs, at Maryvale Creek, and along the Burdekin river. They have furnished numerous remains of living and extinct marsupials, such as *Diprotodon australis*, *Macropus titan* *Thylacoleo*, *Phascolomys*, *Nototherium*, &c.; a Struthious bird (*Dromornis australis*), and

remains of reptiles and fishes. The deposits of the beautiful Chillagoe caves in the north have also furnished a few bones, and may be expected to be a rich source of interesting organic remains when they come to be thoroughly explored.

Queensland is famous for its rich tin and copper deposits, and with such districts as Chillagoe, Herberton, and Cloncurry she will doubtless take the lead amongst the states in the production of these metals. It is true that the output of both in 1900 was smaller than it was in 1894—when the figures stood at 2871 tons of tin, valued at £102,277, and 415 tons of copper, valued at £9582—but with the advance in prices, which has led to a brisk demand for properties known to contain these metals, the old productivity will doubtless be restored, if indeed it is not exceeded. The following table shows the output of gold and other minerals for 1900:—

	Total Output.		Total Value.	Chief Sources.			
	Ounces	Tons.		Place.	Ounces.	Tons.	Value.
			£				£
Gold	963,189	..	2,871,709	Charters Towers	454,679	.	1,203,166
				Croydon	97,740	..	204,092
				Gympie, &c.	93,522	..	324,154

Lime	..	3,664	3,862	Charters Towers	..	3,594	3,705
				Etheridge	..	70	157

Up to the end of 1900 there had been won of gold 14,837,049 ounces, valued at £50,101,486; and silver, tin, lead, coal, copper, wolfram, manganese, bismuth, antimony, and opal to the value of £10,176,045.

Flora.—There are no mountain ranges of sufficient altitude to make any appreciable change in the plant-life. Bellenden Ker, the highest mountain in tropical Australia, has a height of only 5200 feet, and the plants growing upon its summit, as well as on the highest parts of the neighbouring mountains, are for the most part similar to those on the low lands in the southern parts of the state, and the plants which may be considered as peculiar to these heights are few in number of species. They consist of a Leptospermum and a (?) Myrtus, which attain a height of about 30 or 40 feet, and have wide-spreading, densely-leaved heads. The most attractive of the tall shrubs are *Dracophyllum Sayeri*, of which there are two forms, *Rhododendron Lochæ*, and *Orites fragrans*. A few orchids of small growth are met with, but the only large species known to inhabit these localities is the normal form of *Dendrobium speciosum*. These high spots have a few ferns peculiar to them, and of others it is the only known Australian habitat; for instance, the pretty white-fronded Java Bristle-fern (*Trichomanes pallidum*) has only so far in Australia been met on the south peak of Bellenden Ker; here also *Todea Fraseri* may be seen with trunks 2 to 3 feet high. The sides of these mountains are clothed by a dense forest scrub growth, some of the trees being very tall, but diminishing in height towards the summits. Palms and fern-trees are plentiful, but the greatest variety are met with at about 4000 feet altitude. So far this is the only known habitat of that beautiful fern-tree *Alsophila Rebeccæ* var. *commutata*, peculiar for the wig-like growth at the summit of its stem, which is formed by the metamorphosed lower pinnæ and pinnules.

The Myrtaceous genus Eucalyptus, of which sixty species are found, furnishes the greater part of what is designated "Hardwoods," the kinds being variously termed "Box," "Gum," "Ironbark," "Bloodwood," "Tallow-wood," "Stringy bark," &c. These are mostly trees of large size. Other large trees of the order which supply hard, durable timber are the broad-leaved Tea-tree (*Melaleuca leucadendron* and others), "Swamp Mahogany" (*Tristania suaveolens*), "Brisbane Box" (*T. conferta*), "Turpentine" (*Syncarpia laurifolia*), "Peebeen" (*S. Hillii*), "Penda" (*Xanthostemon oppositifolius*). These are most generally cut at saw-mills. Other orders, however, furnish equally serviceable, large-sized timber, particularly the following:—"Sour Plum" (*Owenia venosa, Meliaceæ*), "Red Cedar" (*Cedrela Toona*), "Crow's Ash" (*Flindersia australis, Meliaceæ*), "Burdekin Plum" (*Pleiogynium Solandri, Anacardiaceæ*), "Bean-Tree" (*Castanospermum australe, Leguminosæ*), "Johnstone River Teak" (*Afzelia australis, Leguminosæ*), "Ringy Rosewood" (*Acacia glaucescens, Leguminosæ*), "Black Walnut" (*Cryptocarya Palmerstoni, Lauraceæ*), "Hill's Teak" (*Dissiliaria baloghioides*). Many trees yield wood particularly adapted for carving and engraving, such as the "Native Pomegranate" (*Capparis nobilis*), the "Native Orange" (*Citrus australis*), "Sour Plum" (*Owenia acidula*), "Ivorywood" (*Siphonodon australe*). Coachbuilders and wheelwrights use the wood of many myrtaceous trees and several others, with Flindersias (*Meliaceæ*), whilst tool-handles are also formed from these and other trees. There is also a large variety of woods, some very beautifully marked, admirably suited for the requirements of the cabinetmaker, and the list of trees furnishing wood for building materials is a long one. Besides the wood value of the trees and shrubs, a large number furnish tannin barks, gums, &c. The tannin barks are mostly derived from various kinds of Acacia, but the barks of the Queensland varieties, of which there are about 120, are not so rich in tannin as those of species belonging to the more southern parts of Australia. Three spice barks, locally known as Sassafras, are employed for flavouring—in the northern parts, *Daphnandra aromatica*, a Monimiaceous tree, and *Cinnamomum Tamala*; and in the southern parts *Cinnamomum Oliveri*. Many indigenous plants are used in domestic medicines, and several are recognized in the Pharmacopæia, such as Eucalypts, Cinnamomums, Sideroxylons, Alstonias, Duboisias, and Pipers.

With regard to fodder-plants, no country is better furnished; the species of grasses are numerous, and the greater part of them highly nutritious, besides which there are many herbs and a large number of salt bushes and other shrubs, which form excellent auxiliaries to the food supply for stock. It is, however, to the grasses that the excellence of the pastures is mainly due. On the extensive plains where the best species abound may be seen a large number of the genus Panicum, of which the following are looked upon with the greatest favour:—"Vandyke grass," a form of *P. flavidum*, "Cockatoo grass" (*P. semialatum*), on the roots of which a species of cockatoo, in some parts of North Queensland, feeds; "Barley grass" (*P. decompositum* and *P. distachyum*); "Blue grass" (*Andropogon sericeus, A. pertusus, A. refractus*, and *A. erianthoides*); "Russell River grass" (*Paspalum galmarra*, nearly allied to the South American species *P. paniculatum, P. minutiflorum*, and *P. brevifolium, Agropyrum scabrum*); "Tall Oat grass" (*Anthistiria avenacea*); "Landsborough grass" (*Anthistiria membranacea*); *Danthonia racemosa, D. pilosa, D. pallida*, and *D. semiannularis; Sporobolus Benthami*, an excellent species found near the Diamantina and Georgina rivers, and *S. actinocladus; Stipa aristiglumis, Leptochloa chinensis, Microlæna stipoides*; "Early spring grass" (*Eriochloa punctata*), with the following "Love grasses":—*Eragrostis Brownii, E. chætophylla, E. pilosa*, and *E. tenella*. The "Mitchell grasses" (*Astrebla pectinata*) and its varieties, viz., the Wheat (*triticoides*), the weeping (*elymoides*), and the curly (*curvifolia*), are those that have the most extraordinary vitality, but some stockholders consider that the "Sugar grass" or "Brown Top" (*Pollinia fulva*) surpasses them in its quickness of bursting into leaf with the first showers of rain.

Amongst the fruits are *Antidesma Bunius, A. Dallachyanum, A. erostre, A. Ghæsembilla*, and *A. parvifolium*, called cherries or currants according to the size of the fruit they bear, the jelly made from the fruit of some species being in nowise inferior to that made from the European red currant. The Kumquat or lime of Southern Downs country (*Atalantia glauca*) makes a peculiarly nice-flavoured preserve. Of the allied genus Citrus two species are met with in the south, *C. australis*, which has a round fruit 1 to 2 inches in diameter; the other, *C. australasica*, with long finger-like fruits 3 or more inches long and about 1 inch in diameter; of this a red variety (*C. inodora*), which is only met with in the tropics, bears a fruit often 2½ inches long by 1¼ in diameter. All these fruits are juicy, and of an agreeably sharp, acid flavour. "Davidson's Plum" (*Davidsonia pruriens*) is a fruit with a sharply acid, rich, plum-coloured juice, sometimes attaining the size of a goose's egg. Of the genus Eugenia, over thirty are indigenous, and fully one-third produce more or less useful fruits. One Fig (*Ficus gracilipes*) produces a fruit used for jam and jelly. Two Garcinias are recorded as indigenous, but of one only (*G. Mestoni*) is the fruit known. It is of a depressed globular form, sometimes 3 inches in diameter, very juicy, and of

a pleasant flavour. *Leptomeria acida*, one of the very early fruits used by Australian colonists, is met with in some localities. The "Finger Berry" or "Native Loquat" (*Rhodomyrtus macrocarpa*) makes a good jam, but is in bad repute for use in the raw state, perhaps owing to a peculiar fungus at times found to infest the berries. The Queensland Raspberry (*Rubus rosæfolius*) is widely spread and commonly used, but the fruit is rather insipid. The representatives of the genus Vitis all belong to the sub-genus Cissus; several of them, although somewhat acrid, are useful for jam and jelly: probably the best for the purpose is one met with near the Walsh river, *V. Gardineri*, which is said to bear bunches from 1 ℔ to 2 ℔ in weight, the berries being large and of pleasant flavour. A large number of nut-like fruits are used by the aborigines for food, but the only one used by the white population is the fruit of *Macadamia ternifolia*, the Queensland nut.

The foliage of many plants yields by distillation essential oils, particularly Eucalypts, Backhousias, and other Myrtaceous plants, as well as some belonging to Rutaceæ and Labiatæ, especially the genus Mentha. Apart from plants of economic value, there is a profusion of ornamental plants, shrubs, trees, and parasites. Of ferns, one-half of the kinds met with in Australia are found in Queensland as well as in the other states, one-fourth in Queensland alone, the remaining fourth belonging to the other states, but not to Queensland. The indigenous ferns equal in number those of New Zealand, and are three times the number of those of Great Britain.

Fauna.—The land fauna of Queensland is essentially one with that of the entire continent. It presents the same old-fashioned aspect, with its antique transition-forms mingled with a vast number of animals arrested in their development through untold ages. But the geographical position of the state, which exposes it to the climatic and transporting influences of the intertropical Pacific, has to a notable extent impressed on its fauna characters of its own. It has thus been made the headquarters of Australian bird-life on land and fish-life at sea, the moisture of its coastal regions and the warmth of its tidal waters being eminently favourable to that wealth of insect and other low types of life which determines the multiplication of the higher. The barrier reefs are thickets of corals of the most varied forms, in life glowing with colour, in death shrubs of snowy purity. Among the shell-fish conspicuous for beauty or rarity are the exquisitely delicate Paper Nautilus and Venus Comb (*Murex tenuispina*), the orange and other valuable cowries, and the gigantic Clam-shell, which may require a ship's tackle to lift it from its bed. On the land surface, among its lowly organized products, interest centres in the multitudinous forms of insect life, of which, excepting the Butterflies and Moths (Lepidoptera) and Beetles (Coleoptera), comparatively little is known at present. Insects inimical to man, with the exception, in some localities, of ants, flies, and mosquitoes, are inconsiderable in number, and possess few hurtful properties. Centipedes, scorpions, and leeches are less troublesome than in most other tropical regions. Spiders present themselves in astonishing variety, but only one kind, a small black spider with red spots (*Lathrodectus*), is malignant. Among the larger insects proper, the great-winged Phasmas, the Skeleton or Stick-insects, the Leaf-insects, and the splendid Swallow-tailed Butterflies, are especially notable. Many of the Beetles are remarkable for size or brilliancy of colour. Turning to the Vertebrate classes, that of the Fishes is extraordinarily profuse in diversified forms, the coral reefs being the grazing- and hunting-grounds of hosts of gorgeously decorated fish, chiefly of the Wrasse family; these, however, are almost equalled in beauty by the Chætodons, Gurnards, &c., of other habitats. Among the Perches are the enormous Groper, which may attain the weight of 4 cwt., the Murray Cod, and the Giant Perch, both excellent food-fish of about 70 ℔ in weight. Sharks of many species abound, but there is no evidence that the Port Jackson Shark (*Cestracion*), which has been claimed for Queensland, extends its range into her waters. The fish which continues to excite the keenest interest in scientific circles, as a survival from the mediæval period of geological time, is the Ceratodus or Burnett Salmon, which, formerly inhabiting the headwaters of the Murray, still perpetuates its kind in two of the smaller rivers north of the Bunya range. Batrachians are limited to the frogs and their nearest allies—that is, to the tailless division of the order, the tailed batrachians (newts, &c.) being, as far as is known at present, entirely absent. The greater part of the frogs are arboreal in habit, the most familiar being the large Green Tree Frog. The exuberance and diversity of their food have doubtless been the cause of their differentiation into many distinct species, which enables them to play a very useful part in checking the undue increase of noxious insects. Snakes, on the other hand, are in too great variety for human interests, as they live very largely on insect-feeders. The great majority belong to the venomous Colubridæ, but fortunately the kinds of which the bite is more or less deadly are not numerous, and snake-bite is one of the rarest causes of death. Those with the worst reputation are the Black Snake and the Orange-bellied Black Snake (*Pseudechis*), the Brown Snake (*Diemansia*), the Keeled Snake (*Tropidechis*), and the Death Adder (*Acanthopis*). The principal non-venomous species are the Pythons or constricting snakes, *e.g.*, the common Carpet Snake (*Morelia*), the long lithe Tree Snake (*Dendrophis*), and the Fresh-water Snake (*Tropidonotus*). The Black-headed Rock Snake (*Aspidiotes*), one of the Pythons, is said to reach the length of from 20 to 25 feet, but to be perfectly inoffensive. Several kinds of marine snakes occur on the coasts, and all are to be accounted dangerous. Of reptiles, the most numerous group by far is that of the lizards, which have among them representatives of each of the leading families of the class except the Chameleons. All of them are harmless so far as their bite is concerned, and the great majority of them are useful to man, but the largest, the Monitors, or as they are locally called Iguanas, are decided pests in country poultry-yards; these lizards in ancient times grew to the formidable length of 15 feet or more. The common Sleeping Lizard (*Cyclodus*) is a rare example of a plant-eating lizard, and the western border of the country is crossed by the demoniacal-looking but quite innocent *Moloch horridus* of the far west. Tortoises are exemplified by many forms in the fresh-waters; on the coasts by the Leather-back, the Edible Turtle, and the Tortoise-shell Turtle. Queensland waters are not at present infested by any species of Alligator, though in times past one of large size was a scourge on the borders of the then inland sea. The crocodilian of its coasts is the crocodile of the Indian Seas, which ranges over the whole of the western tropical Pacific, and wanders south into Queensland waters as far as Keppel Bay. In the fresh-water pools of the northern tableland is found a small and harmless crocodile (Philas) of a very uncommon form. The avifauna is to the naturalist exceedingly attractive, for it is full of surprises and interesting lines of research, while to the artist it is a storehouse of form and colour. Where flowering and honey-yielding trees prevail, a profusion of birds seek their food either on the insects attracted by the honey, or, if so fitted, on the honey itself. Accordingly, the most striking feature of the bird-life, amid the forests of Eucalypts and Acacias, is its richness in honey-eaters and insect destroyers. The former, however, taken as a whole, are not a natural group, but include a family of perching birds and a portion of the Parroquet family, both furnished with brush-tongues adapted to the extraction of honey. A second characteristic is the great development of that quaint company, the Bower Birds, among them the Regent Bird, Satin Bird, Cat Birds, &c., constructors of the elaborate playgrounds which have excited so much attention. A third is the presence in one small part of the territory of a Cassowary, and on its seaboard of three kinds of Rifle Birds, both extensions southwards of the tropical families of Cassowaries and Paradise Birds. In the same region of prolific vegetation the handsome fruit-pigeons are also outliers of a large family of such pigeons spread through the Papuan jungles. On the other hand, one species of that eccentricity in bird-life, the Lyre-bird, represents in the southern highlands its kinsfolk farther south. The Scrub-turkey (*Catheturus*) heaps its mound of rotting *debris* to ferment in the shade of the jungles and give warmth to its eggs; the Scrub-hen (*Megapodius*) piles up sand on the beach for the sun to furnish the necessary temperature. The Giant Kingfisher, otherwise the Laughing Jackass, salutes the rising and setting sun with its discordant cackle, secure in its ill-deserved reputation for benefits bestowed and in oversight of mischief done by it. The comparative paucity of birds of prey (*Falconidæ*), and the almost total absence of rasorial game- and poultry-birds, may be noted. Birds pursued for sport or profit, however, are not wanting. The Emu and the Bustard or Plain Turkey afford sport in the open country, Quail and Snipe in or near the timber, while rivers and lakes still unvisited by the gun are covered with Ducks and Geese, Swans and Pelicans. It has been said that Australia has no migratory birds: this is an error, founded upon an undue restriction of the term migratory. Several species could be mentioned which are truly migratory in Queensland, as the Drongo-shrike, Bee-eater, Dollar-bird, &c. On the whole, it may be remarked of the Queensland avifauna, as of its fish resources also, that, owing to life-conditions in both cases, its constituents have but little disposition to associate—in the one case in flocks, in the other in schools. One may meet with mobs of White Cockatoos or Kites, but as a general rule a visitor from Europe misses the frequent flights of small birds to which he has been accustomed. As to quadrupeds, the prevalence of Marsupials has led many to suppose that Australia has bred nothing but these. This is quite a mistake. It is true that Queensland has no indigenous cattle, and only one native carnivorous beast, the Dingo, though the Seals of the southern coasts range almost, if not quite, within her boundary. Two classes of the superior mammals, however, are fairly represented, the Bats (*Cheiroptera*) and the Rodents. Of these latter, Rats and Mice of native origin are in considerable variety; among them are the Jumping Rats (*Hapolotis*), Jerboa-like little animals, which are seldom seen. The Bats are of several species; the most notorious of them are the great Fruit-Bats, or Flying-Foxes, which the fruit-grower could well enough spare. The Sirenian Mammal, the Dugong, haunts

nearly the whole of its coast-line. Queensland, in common with the rest of Australia, has those two strange egg-laying beasts, the Echidna, or Porcupine Ant-eater, and the Ornithorhynchus, or Platypus, two most remarkable milk-yielding mammals without mammæ that have not been able to divest themselves of the mode of generation and much of the structure of their reptilian forefathers. With regard to the intermediate and predominant class, the Marsupials, one of the most interesting forms is the Tree-Kangaroo (*Dendrolagus*), as, apart from the habit of climbing trees, which is shared to some extent by the Rock-Wallabies, they afford a proof of the one-time continuity of the fauna with that of the islands to the north, when land communication still existed between the two areas. Of these curious animals, two species at least are known. As to the rest of the Marsupials, there is of course a general resemblance to those of the continent as a whole, but this is accompanied by much evolution of forms, especially among the smaller sorts, recognized by differences which are occasionally sufficient to mark off distinct generic, or even more differentiated groups. The larger Kangaroos are pretty conservative in character everywhere, while the common Wallabies, the Rock-Wallabies, and the Kangaroo-Rats exhibit a greater tendency to differ from their southern and western kindred. The Koala, or native Bear, is almost absolutely invariable, a sign of the antiquity of the race. The Opossums and the so-called Flying-Opossums are not many in species, and are dwarfed descendants from a more flourishing ancestry. The Bandicoot family (*Peramelidæ*) is fairly represented; it includes the Rabbit-Bandicoot, which crosses in its eastern range the western border of the country. Carnivorous Marsupials of destructive powers are few; the largest of them, the spotted-tailed Native Cat (*Dasyurus maculatus*), is the most troublesome. Superior in size to the domestic cat, this pretender to the rank of cat is able to devastate a whole hen-roost in a single night, and is even said by the aboriginals to attack their infants. With the exception of a smaller species of the same kind, and a brush-tailed ally very much smaller, but yet able to kill a fowl with a single bite, the rest (Marsupial mice) are but partly carnivorous, chiefly insectivorous, and therefore useful. This fauna is now fortunately deprived of the Thylacinus (Native Tiger) and Sarcophilus (Native Devil), which have been driven by physical changes southwards to Tasmania, and, it was thought until lately, of the Wombats, but a new species of these inoffensive burrowers has recently been discovered within the southern borders of the state. One other peculiarity in the form of a marsupial mammal is the little Musk-Rat (*Hypsiprymnus*), inhabiting those northern scrubs which are so prolific in other animal forms foreign to the rest of Australia, and seem to have received some of their denizens from the Indian Archipelago and some from the Papuan Islands. The remarkable deposits of fossil bones, extending in patches throughout the length of the country, are sufficient proof that in former times a much larger number of animals were supported by it than are now to be found within its borders. That their diminution was not due to a permanent decrease in the fertility of the land is obvious, since this is now depastured by vast numbers of stock of all kinds. Nor is there any reason to suppose, as has been done, that it ensued from the advent of aboriginal man with his supposed attendant the dog, for these are not exterminating agents, as Africa and America prove. The fact is sufficiently explained by that law of organic life which gives to each individual, species, family, and class, its period (long or short according to its organization) of development, maturity, decay, and death. In the age when these deposits were formed, marsupial life was probably at its best; since then it has, independently more or less of physical conditions, gradually declined. No amount of sustenance can rejuvenate or even uphold a being which age is rendering incapable of sustentation. It is sad to see in this resourceful country a moribund fauna, brute and human, but the obsolete and refractory must pass away, that the country they occupy may be put to better uses.

Fisheries.—Numerous varieties of well-known and undescribed species of fish frequent the coast, which extends from 28° S. for 2000 miles along the Tasman and Coral Seas and the Inner Route to the tropical waters of Torres Strait up to 10° S. One of the best known variety is the sea mullet (*Mugilidæ*), large shoals of which strike the Australian coast 100 miles south of Sydney, and travel northwards, arriving on the southern coast-line of Queensland in the months of April and May, crossing bars and ascending rivers on the appearance of south-easterly weather. These magnificent fish often attain a weight of from 10 ℔ to 12 ℔, and are the great annual harvest of the fishermen, who forward them to cooling and freezing chambers at the principal ports, and, packed in ice, to up-country towns. Small schools of bream succeed the mullet, and are followed in September and October by the poombah or taylor fish, a fish of exceptional flavour, and much esteemed by epicures. These are succeeded by jewfish, specimens of which caught in southern waters have been known to exceed a weight of 50 ℔, whiting, garfish, and flatheads, while flounders, black and tongue soles are occasionally caught by seine or hauling nets. White and black trevally, groper and rock cod, and a variety of bonito identical with the tunny of the Mediterranean Sea, are also frequently met with. Several species of the tassel fish (*Polynemus macrocohoir*), from which isinglass is procured, have been taken by fishermen. The celebrated lung fish or *Ceratodus forsteri*, also known as the Burnett or Dawson river salmon, remarkable for possessing a rudimentary lung in addition to ordinary gills, perhaps enabling it to live independently of a vitiated water supply, attains a length of 6 feet, and is valuable as an article of food, its pink flesh bearing a resemblance to that of the English salmon. Kingfish, batfish, gurnards, and eels of many varieties are also common. Although seine or hauling nets are commonly used for taking fish, fish-traps are largely utilized on the northern seaboard. Schnapper, bream, rock cod, parrot-fish, and groper are caught by hook and line in from 10 to 30 fathoms of water off the rocky headlands of the southern coast, and brought in well-boats alive to market. Sardines, whitebait, and sprats make their appearance in large shoals on the coast at intervals. The barramundi (*Osteoglossum leichardti*), which occurs in the Dawson and western waters, is found also on the east coast,

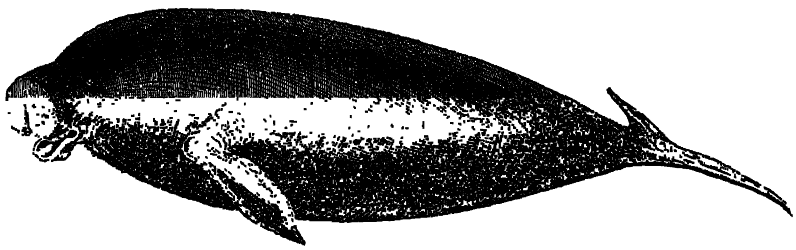

FIG. 1.—The Dugong.

and is one of the most esteemed fresh-water fish in Queensland. Dugong, which are found in herds along the northern coast and as far south as Moreton Bay, are caught in set nets of 36-inch mesh, 100 fathoms in length. A full-grown dugong (Fig. 1) will measure 11 feet, and weigh from 11 to 13 cwt.: they suckle their young, and their food consists of marine grasses; their flesh when cured like bacon is highly valued, and the oil forms a substitute for cod-liver oil; tusks and rib-bones are utilized for handles in cutlery, and the hides when tanned make excellent mill-belts. Different varieties of turtle are plentiful, the green edible turtle being caught by large set nets, and preserved and tinned for export. In Torres Strait and the northern coast the hawksbill turtle, yielding the valuable tortoise-shell of commerce, is said to be captured in a peculiar manner, the sucking-fish or remora (*Echeneis naucrates*) being utilized by the islanders for that purpose. The remora is carried alive in the bottom of the canoe, a long thin line being attached to the fish's tail and another usually to the gill. On a turtle being sighted and approached to within the length of the line, the sucking-fish is thrown towards it, and immediately it swims to and attaches itself by its singular head sucker to the under surface of the turtle, which if of moderate size is easily pulled into the canoe.

Amongst the crustacea may be enumerated the gigantic clams which are found on the reefs of the Inner Route. Occasionally some are met with weighing nearly half a ton, embedded in coral,

FIG. 2.—The Squat Lobster.

and it has been reported that while natives have been wading at half-tide over the reefs, they have stepped into the open shells, which have immediately closed on their feet, from which position they have been rescued with difficulty by their companions cutting the shell open with tomahawks. Fresh-water clams are found in

the rivers in the northern districts. The edible oyster (*Ostrea graminifora*) has for nearly twenty years been largely cultivated in southern Queensland, the exports to the southern states in 1892 rising as high as 18,000 bags, valued at £22,000, producing a revenue for that year of £6200; but this successful return received a severe check in the following years when a small red worm made its appearance amongst the oysters, causing heavy loss (Figs. 3 and 4). Amongst other crustacea, the squat lobster (*Themis orientalis*), is, with giant prawns and quampi, or small golden-lipped pearl shell, obtained by trawling in the southern waters (Fig. 2). Many varieties of crabs are also found on reefs and foreshores at low tide; prawns and shrimps are caught, dried, and form an article for export to China; mussels, pinna or razor-shell, cockles, and eugaries (a species of small shell-fish) are also abundant. The pearl shell fishery, located in Torres Strait, has for over twenty-five years given magnificent returns on the capital invested. Pearls of great value are occasionally obtained, and the shells realize from £100 to £150 per ton in London. As an instance of the value of this industry, it may be stated that in 1898, £100,000 worth of shell was exported to London, bringing in a revenue of £1100 to the Government, the shell having been to a great extent collected off the shallow reefs; diving is now prosecuted in deep water of 25 fathoms and upwards, causing frequent and fatal accidents to divers engaged. Bêche-de-mer, or holothuria, or trepang, has been collected, cured, and exported from the reefs and adjacent seas for over thirty years, the yearly value of the exports occasionally exceeding £30,000, though of late years the industry has not been so remunerative. Schools of whales are occasionally sighted on the coast, but the old fishing grounds at the Bamptons, 450 miles distant across the Coral Sea, are seldom visited. Amongst the dangerous and voracious classes of fish frequenting the warm waters of Queensland, which are common to both temperate and tropical seas, may be enumerated sharks of all varieties, gigantic sword-fish and saw-fish, and immense stinging rays.

Fig. 4.—Mangrove Oysters, Moreton Bay.

Population.—The population has increased from 326,916 in 1885 to 502,892 (census preliminary count) on 1st April 1901—280,504 males and 222,388 females. Included in these are coloured aliens, estimated to be Polynesians, 8826; Chinese, 10,076; Japanese, 3063; Javanese, 298; other Asiatics, 2357; total, 24,620 persons, or about 5 per cent. of the total population. The density of population in 1901 was 0·75 per square mile, compared with 0·32 in 1881 and 0·59 in 1891. Persons engaged on sheep and cattle runs numbered 17,500; in agriculture, 40,700 males and 7500 females; in mining, 14,000; in industries and manufactures, 20,000 males and 6400 females; in building, road-making, and the like, 13,000. Trade and commerce utilize 19,200 males and 2400 females; transit and transport, 15,800; domestic occupations, 18,000 females and 7200 males; professions, 9100 men and 3700 women. Of the rest, some 20,000 manual labourers are not constantly in any one branch of work, and about 1000 men and 250 women live on their means. The birth-rate is now 30·19 per 1000, showing a gradual decline from 43·07 per 1000 for the period 1861–65, 36·37 per 1000 for 1881–85, and 35·15 for 1891–95. The illegitimates in 1881 were 4·2 per cent., in 1891 4·7 per cent., in 1900 6·40 per cent. In 1900 there were born 7599 boys and 7202 girls (14,801 in all). The death-rate is 11·72 per 1000, showing a remarkable diminution, for in 1861–65 it averaged 21·06 per 1000; in 1871–75, 17·94; in 1881–85, 19·10; and in 1891–95, 12·82. The deaths in 1900 numbered 5747 (males, 3678; females, 2069). The marriage-rate in 1900 was 6·88 per 1000, being a decrease on the figures for 1885, owing to the age-condition of the population having reached a more normal level. In 1890 the poll tax on Chinese was abolished, but their arrival was restricted to one person for every 500 tons of the ship's register. The aborigines have diminished in numbers very fast in the south, and they are no longer wild and ferocious, except in a few remote parts of the north. Protection is afforded to them in their dealings with whites, and several missions at Bellenden Ker, Bloomfield, Cape Bedford, Deebing Creek, Maria Yaamba, Mackay, Mapoon, and Weipa have done good work amongst the children. Their numbers are now estimated to be 10,000 persons.

Agriculture.—Agriculture is a thriving industry, employing a considerable percentage of the population. It has largely taken the place of sheep-raising on the Darling Downs and cattle-raising on much of the coast country in the south, whilst farther north

sugar and other tropical products have led to the cultivation of the rich scrub land at the mouths of coastal creeks and rivers, the total area of land under cultivation for 1900 being 479,716 acres, against 209,130 acres for 1885. Sugar produced in Queensland in 1885 equalled 55,796 tons, and in 1899, 123,300 tons. It is principally grown at Logan, Maryborough, Bundaberg, Rockhampton, Mackay, Bowen, Burdekin, Ingham, Johnstone river, Mossman, and Cairns. There are now two refineries and fifty-eight sugar-making mills in active work. It has long been recognized that only well-equipped mills are able to manufacture sugar at a profit at the low price to which the competition of bounty-fed sugar has now reduced this article, and, whilst many mills are still owned with the plantations, a different system has sprung up by which farmers cultivate comparatively small areas of cane, and either sell to owners of mills or combine and erect a mill themselves (in which they are liberally assisted by the Government), and after receiving a price per ton for their cane, divide whatever profits there are over working expenses, interest, &c., at the close of the season. The central mill system, by extending the growth of cane by small farmers, will, it is believed, solve the troublesome question of black labour in connexion with this industry, besides having the effect of settling a large number of persons on farms of their own. The production in 1900 reached 92,554 tons. Another large agricultural product is wheat, and of this there was produced, in 1897, 1,009,293 bushels, the yield for 1900 being 1,194,088 bushels from 79,304 acres, against 51,598 bushels for 1885. The centres of wheat production are the Warwick and Toowoomba districts. Indeed, the Darling Downs produce nineteen-twentieths of the whole of the wheat grown. Barley, ordinary and malting, is also grown in the same district, and two malting-houses exist for converting it into malt. Maize is grown extensively, but owing to drought in 1900 did not suffice for local requirements. The produce for 1900 was 2,456,647 bushels, against 1,574,294 bushels for 1885. Rice is an industry of comparatively recent introduction, and although small areas are grown at many places, Cairns is the centre of the industry. There were 271 acres, yielding 6870 bushels of paddy grown in 1900. Potatoes are reared principally in the south; there were 20,014 tons grown in 1900, against 8326 tons in 1885. Sweet potatoes are also grown extensively. Arrowroot is grown almost entirely in the south, where, besides supplying local requirements, 463,617 ℔ of manufactured arrowroot were exported in 1900. The production for 1900 was 3978 tons of tubers, and in 1885 it was about 3855 tons. Coffee is attracting attention, its cultivation being principally in the north. Bananas grow along the whole seaboard, and form an important industry; thousands of bunches are exported weekly from the northern ports to the southern states. The production for 1900 was 2,313,108 bunches, against 1,660,180 dozens for 1885. Tobacco yielded 4032 cwt. of cured leaf in 1900, against 1330 in 1885; pine-apples, 424,835 dozens in 1900, against 122,263 in 1885; oranges, 2,356,068 dozens in 1900, against 658,549 in 1885; mangoes, 277,444 dozens in 1900; and strawberries yielded 401,105 quarts. Though grape-vines grow throughout Queensland, they are best suited for wine-making in the south of the state.

Stock-Raising.—Although farming has advanced rapidly and displaced pastoralists near the centres of settlement, the pastoral industry still retains the premier place. The number of sheep increased from 8,994,322 in 1885 to 17,552,608, but has fallen through the severe and protracted drought to 10,339,185 in 1900. Cattle have decreased from 4,162,652 to 4,078,191, whilst the value of wool exported rose from £1,779,682 to £2,199,370. The more thorough opening up of the country, better means of communication, lower rents, and longer tenure have all combined to induce pastoralists (both sheep and cattle) to occupy the more remote districts, leaving the more accessible parts to settlement. The discovery of artesian water has enabled them profitably to stock and use country which, though rich, is devoid of natural water. There are now more than 439 artesian bores in operation, the outflow from which is calculated to exceed 268 million gallons daily. In addition to this creeks are dammed and excavations made in suitable localities, and large sums freely spent in the endeavour to retain a permanent supply of the precious fluid. The character of sheep-farming, too, has altogether changed. Instead of the sheep being herded by a man who accompanied them through the day and yarded them at night, they are allowed to go at large in paddocks many miles in extent and surrounded by wire fences, and only mustered when required. Men are employed to keep the fences in good order and poison the dingoes. This system and the artesian bores together are changing the character of squatting, and good land, where water can be obtained, is now largely sought after in blocks of 20,000 acres. In future smaller holdings of 10,000 sheep will take the place of the larger holdings of 300,000 sheep, the former plan also giving employment to a larger number of persons. Shearing by machinery, too, is having a good effect on the values of wool. Cattle, which a few years ago sank to an almost nominal price, have again risen in value, and promise to increase. A market for frozen meat having been found in England, meat works were established which are able to send fresh meat to any port in the world in a perfect state of preservation. Preserved meat in tins and in extract, and a large variety of subsidiary products are also exported, and no portion of the animal killed is wasted. Fourteen freezing works and eleven preserving and boiling-down works are now running, most of them fitted with the latest appliances for economically reducing cattle to marketable products. The value of frozen meat exported in 1900 was £982,125, whilst preserved and salt meats were £490,811, and extract of beef £89,011, hides and skins £551,752, tallow £397,439, miscellaneous products of the industry £628,277, making altogether £3,049,415, and, including wool, a sum of £5,248,785 as the value of the pastoral produce in excess of the requirements of the state. A small insect pest call the "tick" has caused much loss in the north, and has gradually spread southwards. It is believed that inoculation will render cattle immune, and that the losses sustained in the north will not be repeated in the south. Dairy-farming has latterly received much attention, and promises to attain considerable dimensions. This also depends on the cheapness of cold storage, since the local consumption of butter has been overtaken, and the exportation of that article is largely on the increase. The best breeds of milking cattle have been extensively imported, and feeding and treatment have been assimilated to British methods, whilst co-operation amongst dairy-farmers has led to the establishment of creameries and butter factories in many parts of South Queensland. There were 1,389,250 ℔ of butter exported in 1900, of the value of £51,729. Horse-raising has become an important industry, the number of horses now approximating half a million. There has also been a large increase in pigs, namely, from 55,843 in 1885 to 122,187 in 1900. Within the last few years bacon-curing factories have come into existence, with the result that whilst bacon and ham were imported to the value of £29,969 in 1885, they formed in 1900 exports to the value of £46,866. These factories purchase pigs from the farmer and convert them into bacon, ham, lard, &c. They are all fitted with refrigerating machinery, and carry on their operations throughout the year.

Commerce.—Since 1885 the coastal towns have grown steadily in size and importance, and the trade passing through them has increased. The total exports for 1900 were £9,581,562, or £20 per head (1882 = £3,534,452), of which wool represented £2,199,370 (1882 = £1,329,019); gold, £2,819,495 (1882 = £829,655); tin, £79,958 (£269,904); live stock, £597,474 (£280,466); green fruit, £104,387; sugar, £669,389 (£153,188); tallow, £307,439 (£129,549); preserved meats and extracts, £1,562,197 (£119,343); pearl-shell, £128,524 (£105,869); hides and skins, £551,752; bêche-de-mer, £4376 (£25,032). The principal articles of export for 1900 may be grouped as follows: pastoral products, £5,248,785; mineral, £2,984,689; and agricultural, £904,171. The imports for 1890 were £7,184,112, or £14 13s. 0d. per head (1882 = £6,318,463), and it is noticeable that in 1892, the time of financial troubles, imports fell to less than five millions. The imports for the years instanced show for manufactured cotton, silk, and woollen goods, 1900, £819,118 (1882 = £839,352); unmanufactured, £486,299 (1882 = £194,489); metal goods and hardware, £1,221,145 (£910,029); flour and grain, £390,967 (£453,307); oilman's stores, £77,806; spirits, wines, and beer, £282,460 (£320,925); books and stationery, £184,987 (£113,798); tea, £135,637 (£109,286). During 1900 there entered 713 sea-going vessels with a tonnage of 835,355, and cleared 716 with a tonnage of 819,662. A dry dock with all conveniences exists at Brisbane, and slips for smaller vessels at the larger ports. Dredgers are largely employed in improving and deepening the rivers and harbours, of which the principal are Brisbane, Maryborough, Bundaberg, Gladstone, Rockhampton, Mackay, Bowen, Townsville, Dungeness, Geraldton, Cairns, Port Douglas, Cooktown, and Thursday Island, all on the eastern coast, and Normanton and Burketown in the Gulf of Carpentaria. The project of opening a port at Point Parker has been abandoned.

Manufactures.—The abundance of raw materials, and the free entry of articles imported for manufacture, have tended to develop industries of all kinds, and whilst the number and description in 1885 were few, great progress has taken place in later years. Large foundries and engineering shops exist in all the principal towns, and there are, besides, flour, sugar, and saw mills; breweries; ice, butter, cheese, tobacco, jam, pickle, clothing, and boot factories; meat preserving, boiling down, and soap works; tanneries; distilleries; wine making; and a woollen manufactory. The total number of establishments is 2610, and for 1899 they employ 28,883 hands, and utilize 27,580 horse-power. The value of the output in 1899 was £8,883,231. Electric light is largely employed, and all the principal towns are lighted with gas.

Railways.—Since 1885 good progress has been made, not only in extending the main trunk lines, but in constructing branch and other lines to meet local requirements, the total length of railways open to traffic having increased from 1434 to 2801 miles, at a total cost up to the 30th June 1900 of £19,803,239. The Southern

line, which in 1885 stopped at Stanthorpe, has now been extended to Wallangarra, where it connects with the New South Wales system, affording rail communication from Brisbane with Sydney, Melbourne, and Adelaide. Branch lines exist to Killarney, Allora, and Pittsworth. The Western line passing through Darling Downs has been extended from 415 miles, or 97 miles west of Roma, through the rich pastoral country of the Warrego to Cunnamulla (604 miles), and about 64 miles distant from the New South Wales boundary. Besides branch lines completed to Dugandan, Esk, and Crow's Nest, a line has been built from Brisbane to Southport, 50 miles, with branches to Beaudesert and Nerang, as well as a line to Cleveland. The North Coast line has been built connecting Brisbane with the Gympie-Maryborough Railway, and continuing on to Bundaberg and Gladstone, 328 miles, whence it will shortly be extended to Rockhampton. At present a steamer conveys mails and passengers for Rockhampton and the west from Gladstone to Broadmount, through the smooth water of the Narrows, thence by rail to Rockhampton. Branches exist on the North Coast line to Enoggera, Penkeuba, Sandgate (on Moreton Bay), Kilkivan, Degilbo, Cordalba, Pialba, and Mount Perry. The Central line, which in 1885 extended from Rockhampton to the Alice river, now reaches Longreach on the Thomson river, 427 miles, and in addition to the Clermont branch, other branch lines have been built to Springsure, Emu Park, Broadmount, and Mount Morgan. Passing north, a railway line has been built from Mackay, 23 miles, through the sugar country. The Northern line commencing at Townsville has been extended from Torrens Creek, through Hughendon to Winton, 367 miles, and has a branch to Ravenswood. The respective termini of the Central and Northern lines are now about 110 miles apart, and give railway communication to a vast extent of magnificent open downs of the richest soil, and comprising some of the finest sheep country in Queensland. Since 1885 lines have also been constructed from Bowen to Wangaratta, 48 miles, from Cairns, past the celebrated Barron Falls to Mareeba, from Cooktown, an additional 36 miles, towards the Palmer goldfields, and from Normanton to Croydon goldfield. In addition to the 2801 miles of Government railways open to traffic, the Clullagoe Railway, starting at Mareeba, and several steam tram lines have been built by private enterprise, whilst others are under construction, and proposals have been made for several additional lines. In 1899–1900 the railway earnings amounted to £1,464,399, and the working expenses to £948,691, the net balance being equal to 2·67 per cent. on the invested capital.

Administration.—At the head of affairs is the governor, who is appointed by the Crown. In the conduct of his office he acts through and with an executive council. Parliament consists of two Houses—the Legislative Council of forty-one members (though the number is not fixed), nominated by the governor for life, and the Legislative Assembly of seventy-two members, elected by ballot on practically manhood suffrage from sixty-one electoral districts. Their period of office is three years, and they receive a fee of £300 a year, besides travelling expenses. In these Houses is vested the power of making laws and imposing taxes. For purposes of local self-government the state is divided into thirty municipalities, six shire councils, 117 divisional boards, and 100 petty sessions or police districts. The boroughs and shires control 430 square miles, and in 1900 their revenue was £369,322 and their expenditure £391,578. The divisional board controls 667,823 square miles, and in 1900 their receipts amounted to £271,301, and their outlay to £261,609. Revenue is mainly derived from rates levied on the capital value of assessed properties, which amounted for the state to £41,500,000, representing an annual value of £2,770,000. All improvements are exempt from assessment, and much of the revenue is expended in road-making and the building of bridges. Rates are supplemented by an endowment from the central Government.

Finance.—Revenue is made up to the 30th June each year. In 1900 it was £4,588,207 (in 1884=£2,566,358), being customs £1,461,690 (£866,475), excise £148,423 (£34,442), land sales, &c., £202,281 (£365,536), pastoral rents £323,622 (£254,424), railways £1,422,852 (£582,642), post and telegraph £309,470 (£155,996). The expenditure was £4,540,418 (£2,511,651). In the settled districts pastoralists had so far been replaced by the agriculturists that there were only eleven runs containing 506⅜ square miles under lease, the rent being £737 12s. 2d., against 304 runs, containing 11,162 square miles, paying £21,419 rent in 1883. In the unsettled districts the number of runs had fallen to 2261, containing 351,359 square miles, but paying £290,308 4s. 11d. rent, against 8939 runs, containing 475,601 square miles, paying £216,638 in 1883. Grazing farms numbered 1904, containing 20,375 square miles, paying £83,754 12s. 10d. annual rent, whilst the settled and unsettled portions of runs held under occupation licence numbered 1534, with an area of 54,530¼ square miles, paying £32,292 7s. 3d. annual rent. The absolute public debt in 1900 was £35,898,414 (1884=£16,419,850). Of that amount the indebtedness for railways was over 20 millions (1884=9¼ millions), for immigration 2½ millions (1884=2 millions), and for harbours 2 millions (1884=1 million).

Education.—Public education is free, unsectarian, and compulsory. State or provisional schools are formed wherever an average attendance of twelve children can be got. Theoretically the school age is from six to twelve years, but in practice compulsory attendance is seldom if ever enforced in certain parts, owing mainly to the difficulty of providing suitable schools within reasonable access. In 1900 there were 932 schools in the state, 2217 teachers, and 108,070 scholars. Of private schools the number in 1900 was 173, with 664 teachers and 14,653 pupils. Exclusive of coloured aliens, almost the whole adult population can read and write. In 1900 the sum spent on education was £289,509 13s. 2d. In primary schools the annual cost per scholar, calculated on the net enrolment, was £2 14s. 4¼d. Masters and mistresses of state schools are paid by the Government according to their educational status, the number of children, and the proficiency of instruction. Ten grammar schools are endowed by the state. By a system of competitive scholarships the Government gives free education in grammar schools to scholars in state schools, and also three-yearly exhibitions to universities to students who pass an examination of a high standard. State aid is also rendered to schools of art, schools of design, free libraries, and technical schools. The foundation of a university at Brisbane is now contemplated.

Religion.—There is no state church. Amongst the different denominations the Church of England at the date of the last census numbered 36·21 per cent. of the population, the Roman Catholics 23·56, the Presbyterians 11·59, the Methodists 7·93, the Lutherans 4·43, the Baptists 2·60, the Jews 0·21, and other Christian bodies 13·31. Pagans and Mahommedans 4·43.

Justice.—The law courts comprise a supreme court, with a chief justice and four puisne judges, district courts, and petty sessions courts. In 1899 the number of persons convicted of serious offences was 252, and petty sessions convictions amounted to 18,534. The state police force, including native troopers, exceeds 900 men, and the number of prisons is eighteen.

Defence.—The land force of 6535 men (of whom 321 were fully paid regulars, 4131 militia paid for each day's drill, and 2083 volunteers) costs the state £70,000 a year. Naval defence is provided for by three armed tenders, two gunboats, five naval brigades, and a picket boat. Thursday Island in the Torres Strait has been strongly fortified at the cost of all the states, and is maintained at their expense, the Imperial Government contributing the armament. Queensland's share of the annual charge for the support of the imperial auxiliary squadron in Australian waters came to £14,031 in 1899.

Post and Telegraphs.—Postal communication is well developed. Every vessel is obliged to give notice of intended departure, in order that mails may be shipped. Mail matter is forwarded coastwise by all suitable steamers, whether subsidized or not, and carried on all railways, travelling post offices existing on the main lines to expedite delivery. Coaches carrying mails and passengers connect with all terminal and many other stations, whilst horse mails run wherever the mails to be carried do not warrant coaches. In this manner nearly all pastoral stations are on or near a mail route of one or other kind, whilst the amount of mail matter carried is very great, and continually increasing. In 1898 there were 19,723,905 letters (1885=9,776,407) and 16,778,555 newspapers and packets carried (1885 = 9,949,650) by mail. The number of post offices is 1166, against 623 for 1885. The revenue of the postal department, exclusive of telegraph and telephone, for 1898 was £182,206 (1885=£97,651), whilst the expenses, including telegraph and telephone, amounted to £313,771. Postal notes are largely used, the number of notes issued and paid for 1898 being 481,069, having a value of £183,360. The number of money orders issued and paid was 217,910 (1885=137,479), valued at £835,981 (1885=£514,593). Counting all routes once only, the land distance over which mails are carried is stated to be 32,127 miles. A parcel post was established by the post office in 1892, and has grown to considerable proportions, carrying 238,240 parcels in 1898. Branches of the Government savings bank are opened at each staff post office, besides other places, there being 147 branches now open. Telegraph offices exist in every town, and there are offices in the bush. In most towns they are combined with the post offices. There are 422 offices open (1885=259), there being now 10,088 miles of line open (1885=7533), and 18,565 miles of wire (1885=12,290). The total cost of construction of telegraph lines is £912,175, the revenue for 1898 being £79,831. the number of messages despatched and received being 1,334,846. Telephones are now very largely used in all the principal towns, there being 1516 subscribers. Receipts from telephones amounted to £8896 in 1898. There are eight exchanges, and 1334 miles of wire.

Banks.—Eleven banks have been established. In 1900 treasury notes issued through the banks amounted to £388,833, deposits to £13,653 775, total liabilities to £14,190,560, coin and bullion to

£1,879,326; advances to £12,599,306, total assets to £16,257,443. There were 84,796 depositors in the Government savings bank, with £3,624,740 to their credit.

The writer desires to acknowledge his indebtedness to Mr William H. Rands, the Government Geologist, for notes on the geology; to Mr F. Manson Bailey, F.L.S., for notes on the flora; and to Mr C. W. De Vis, M.A., for notes on the fisheries and on the fauna. (J. V. C.)

II. History.

Queensland was separated from New South Wales by an Order in Council of 13th May 1859. The constitution, which was based upon the New South Wales Act of 1853, provided for 16 electoral districts, with a representation of 26 members. A Legislative Council was also formed, to which the governor of New South Wales, Sir William Denison, appointed 5 members, to hold office for four years, and Sir George Ferguson Bowen, the first governor of the new colony, 8 life members. Mr Robert George Wyndham Herbert was the first premier and colonial secretary, and held office until 1866. Amongst Mr Herbert's colleagues were Mr (afterwards Sir) Maurice Charles O'Connell, president of the Legislative Council and afterwards lieutenant-governor, a representative of the pastoralist interest and a commanding personality; Mr St George Richard Gore; Mr Arthur Macalister; Mr Robert Ramsay Mackenzie, a squatter, and leader of the Brisbane party in the House; the late Mr (afterwards Sir) Charles Lilley, who established free education in 1870; Mr (afterwards Sir John) Bramston; Mr Joshua Peter Bell, treasurer, a prominent squatter and a man of sterling character; Mr T. L. Murray Prior, the father of Mrs Campbell Praed, the novelist; and Mr George Raff, who represented Brisbane trade, and was long an important figure in the financial and commercial life of the colony. There were thirteen appointments in the first administration, and Mr Herbert alone held office uninterruptedly. Of the 39 representatives in the first Parliament, 20 were pastoralists; the others may be roughly classed as barristers, solicitors, and merchants. The pastoralists were the pioneers of settlement in the colony; those best known were the Archers of Gracemere, the Bells of Jimboor, the Gores of Yandilla, the Bigges of Mount Brisbane, Mr (afterwards Sir) Arthur Hodgson, Mr Robert Ramsay, Mr Gordon Sandeman, and Messrs Kent and Wienholt. The white population at the end of 1859 was 25,788, and the exports were valued at £500,000.

Mr Herbert's Administration, 1859–1866.—The first Parliament was opened on 29th May 1860. The providing of revenue and the establishment of immigration were the chief matters for consideration. The treasury was practically empty, but Sir Saul Samuel, treasurer of New South Wales, took a broad and generous view of the situation, and rendered financial aid, whilst in 1861 the first Government loan of £123,800 was authorized, the money being appropriated to public works and European immigration. Labour was so scarce that as early as 1851 the squatters had imported Chinese; various schemes for the introduction of coolies on a large scale were now mooted, but public opinion was decidedly against any increase in the number of coloured aliens then in the colony. Other matters requiring the attention of Parliament were the encouragement of settlement throughout the colony's gigantic territory, the discovery and exploitation of her natural resources, the establishment of connexions with the outside world, the construction of railways and telegraphs, education, State aid to new industries, and exploration of the unknown country in the north and west. In 1859 the educational system was a mixed national and denominational one; there were 10 schools of the latter class, 1 of the former, and 30 private schools. In 1860 a Board of General Education was established, which extinguished the denominational system and placed the schools under State control. In the same year State aid to religion was abolished. At this time there were 18 places of worship existing, and 3523 persons were returned as attending divine service. The governor, in opening Parliament in 1863, pronounced decisively against the reintroduction of convicts. In that year Queensland boldly grappled with the extension of colonizing, and a settlement was established at the northerly point of Cape York peninsula by Mr Jardine. During the following two years ports were opened along the coast, and pastoral occupation spread far into the northern and western interiors. The first sod of the first railway, from Ipswich to the Darling Downs, was turned on 15th February 1864. On 1st February 1866 Mr Herbert retired, and Mr Macalister became premier and Mr Mackenzie colonial secretary. In the following July the failure of the Overend and Gurney and Agra banks, in the latter of which the Government had public moneys, caused the collapse of a loan which was being negotiated in London. A panic followed: the Government could not pay the railway contractors, and the navvies employed by them started for Brisbane, threatening to hang the ministers and loot the town. On arrival, however, they were easily headed off to a reserve. By this time the treasury was empty, general insolvency prevailed, and the community appeared to be wrecked. Treasury bills to the amount of £300,000 were issued, and the governor in council was authorized to legalize Treasury notes, when necessary, as currency, payable in gold on demand, to tide over the crisis. Prior to this, however, the treasurer took preliminary steps to issue £300,000 "Legal Tender Notes"—inconvertible "greenbacks"—but Sir George Bowen informed the premier that he should veto such a scheme, and suggested the issue of Treasury bills. Mr Macalister thereupon resigned, and Mr Herbert, who had made arrangements to proceed to England (where subsequently he became permanent secretary of the Colonial Office), took office again to help the colony through the difficulty. His second ministry lasted for eighteen days, and, having passed the Treasury Bills Act, he retired from the public life of Queensland. The only determined opposition the Herbert ministry met with was from the townspeople's representatives, whose contention was that the squatters dipped too deeply into the public purse for public works expenditure; but an important factor in the early parliamentary days was the opposition between the Brisbane and Ipswich parties in the House, the latter town aspiring to be the capital of the colony.

The Discovery of the Goldfields, 1866–1879.—Mr Macalister returned to power in August 1866, and dealt so vigorously with the after-effects of the financial crisis that by the end of 1867 affairs had approached their normal condition. A new era was now opened for Queensland by the discovery of gold. The Gympie field was discovered by Nash in 1867, and a big "rush" resulted. In 1872 Mr Hugh Mosman discovered Charters Towers, the premier goldfield of the colony; and Hann, the rich Palmer diggings. Other important discoveries were also made, and Queensland has ever since been a gold-producing colony. Mining is the foundation upon which much of the progress of the colony has been built, and the legislation and records show continuous traces of the influence of the gold-getter. In 1873 Mr John Murtagh Macrossan, a digger, was returned to Parliament expressly as a mining representative; and other men of a different stamp from the representatives of the squatters and townspeople, who had hitherto composed the House, now began to enter public life. From 1870 to 1879 progress was satisfactory, trade interests were prosperous, and in this decade the foundations of the public and social structure of Queensland were laid. Agriculture was extended, and sugar growing took the place of cotton cultivation. (The first crop of sugar was grown by the Hon. Louis Hope at Cleveland, about 1862.) Hitherto politics had been non-partisan, and legislation was chiefly of a domestic character. From the time of Mr Herbert's departure until the appearance of Mr Thomas McIlwraith and Mr Samuel Walker Griffith, the two master spirits of Queensland parliamentary life, the political history of the colony was composed of shortlived administrations, with Messrs Macalister, Mackenzie, Palmer, Lilley, George Thorn, and John Douglas (afterwards Government Resident at Thursday Island) as premiers. Mr Arthur Hunter Palmer (whose administration, from 1870 to 1874, had the longest life), a New South Wales squatter, entered the Queensland Parliament in 1866. He was one of the most popular of Queensland's parliamentary leaders, and has left the impress of his labours on the public works, and educational and defence force systems of the colony. In 1870 Queensland was disappointed in her ambition of becoming the connecting point for Australia with the European and Eastern cable systems. A company—the British Australian Telegraph Company—was formed in London to connect Australia by cable with Singapore. The plan provided for a land line from the Queensland telegraphs at Burketown to Port Darwin, in the Northern Territory of South Australia, where the cable was to be landed. Writing on 25th January 1870, the Telegraph Construction and Maintenance Company officially informed the governor of Queensland that it had received a contract from the British Australian Telegraph Company to construct "cables and land lines, to be laid between Singapore and Burketown, in North Australia." The Construction Company deputed Commander Noel Osborn to negotiate with the Governments of South Australia and Queensland in reference to the land line; but on arrival in Adelaide he accepted the offer of the South Australian Government to construct and maintain a telegraph line right across the continent from Port Darwin to Adelaide, and Queensland was informed that the original plan had been abandoned. Although the company was thus saved the expense of making and maintaining the Port Darwin–Burketown line, it was regarded as having broken faith with Queensland, which had specially pushed on her telegraph system to connect with the proposed line. Owing to this feeling Queenslanders have not always had the facilities for cheap cabling to Europe enjoyed by the other colonies, though the subsequent owners of the cable, the Eastern Companies, were in no way responsible for the act of their predecessors.

A resolution in favour of the payment of members was carried in 1871. In 1872 the first Agent-General in London, Mr Richard Daintree, was appointed. The same year the Railways Act Amendment Act was passed, authorizing the construction of railways by private enterprise, land being offered as compensation for the outlay. Electoral representation was increased to 42 members. In January

1874 Mr Palmer resigned, and Mr Macalister came into power for two years, the most important measure of his Government being the State Education Act of 1875, on which the present educational system is based. Both Messrs McIlwraith and Griffith were members of the Macalister ministry, but the former resigned in October 1874, owing to a difference of opinion as to a proposed land-grant railway from Dalby to Normanton. In 1878 Mr (afterwards Sir) James Francis Garrick first became a cabinet minister, joining the Douglas ministry as secretary for public works and mines.

The governors of Queensland from separation to 1901 were:—Sir George Bowen (d. 1899) [1859–68]; Colonel Samuel Wensley Blackall (d. 1871) [1868–71]; the Marquis of Normanby (d. 1890) [1871–74]; Mr (afterwards Sir) William Wellington Cairns (d. 1888) [1875–77]; Sir Arthur Kennedy (d. 1883) [1877–83]; Sir Anthony Musgrave (d. 1888) [1883–88]; Sir Henry Wylie Norman [1889–95]; Lord Lamington [1896–1900]; Sir Herbert Charles Chermside [appointed 1901].

Active Politics, 1879 to 1890.—On 21st January 1879 the first McIlwraith administration came into power, and an important extension of local government was one of the early measures passed, divisional boards being formed to take charge of public works in districts not included in municipalities. In the following session, 1880, the Opposition, led by Mr Griffith, bitterly opposed the Government proposals on Kanaka labour, land-grant railways, and a European mail service *viâ* Torres Straits. The Government, however, concluded an agreement with the British India Steam Navigation Company for a monthly mail service between Brisbane and London for an annual subsidy of £55,000. The Railway Companies Preliminary Act, giving the governor in council power to treat with persons willing to construct railways in return for grants of 8000 acres of land for each mile of rails laid, was also passed. This measure was generally unpopular, and no railways were built under its provisions. During the session Mr Griffith impeached the premier in connexion with contracts for the purchase of 15,000 tons of steel railway metals, and their carriage to the colony, made in London whilst Mr McIlwraith was there in January 1880. A select committee in the colony, and afterwards a Royal Commission in London, subsequently reported in the premier's favour. The discovery of the celebrated Mount Morgan gold mine, and the initiation of artesian well-boring by Mr R. L. Jack, Government geologist, took place in 1881. In 1883 a great drought prevailed, and the compulsory stoppage of public works demoralized the labour market. Early in the year information reached the colony that Germany proposed to annex a portion of New Guinea, which, together with other islands in the Papuan Gulf, was becoming of great strategic value to Australia; and the premier, fearing that it would thus be lost to the empire, instructed Mr H. M. Chester, police magistrate at Thursday Island, to proceed to Port Moresby and take possession of the unappropriated portion of the island in the name of the Crown. This act was afterwards—to the indignation of Australia—repudiated by Lord Derby; and, eventually, under the Berlin Treaty of 1886, England and Germany entered into joint possession of that part of New Guinea lying east of 141° E. In July Sir Thomas McIlwraith (created K.C.M.G. in 1882) was defeated by 27 votes to 16 on a proposal to arrange for the construction of a land-grant railway from Charleville to the Gulf of Carpentaria. The general elections which followed were fought mainly on the questions of coloured labour for the sugar plantations and land-grant railways. The Government was defeated, and Mr Griffith formed his first administration. Later in the year the premier drafted the Federal Council Act at Sydney, and through his efforts Queensland eventually joined the Federal Council of Australasia. In 1884 a 10 million Loan Act was passed, intended to secure continuity in borrowing for railway construction, but many of the lines specified were unsurveyed. According to the view now generally held in Queensland, this loan seriously hampered the colony in after years. In 1887 the number of seats in the Assembly was increased to 72 (the present number), and several reforms were effected in the public service, notably the establishment of the department of agriculture. At the general elections in 1888 Sir Thomas McIlwraith was returned for North Brisbane, defeating Sir Samuel Griffith (who had been created K.C.M.G. in 1886) by a large majority, and resumed office as premier and leader of the "National Party." Ill-health, however, soon compelled him to leave the colony, and he was succeeded by Mr Boyd Dunlop Morehead. Sir Thomas McIlwraith's inflexible nature was evidenced all through his public life. On the death of Sir Anthony Musgrave in Brisbane in 1888, he maintained that the Government should be consulted as to the appointment of the new governor. Lord Knutsford declined to accept this view, and appointed Sir Henry Blake. The premier formally protested, and a deadlock ensued, which was only removed by the resignation of the governor-designate. In 1889 payment of members at the rate of £300 a year, plus 1s. 6d. per mile travelling expenses, was established. In 1890 a financial crisis arose. Sir Thomas McIlwraith had returned to the colony and dissociated himself from the ministry. He conferred on the situation with Sir Samuel Griffith, and a want-of-confidence motion was nearly carried. Mr Morehead resigned, and a coalition ministry, with Sir Samuel Griffith as premier, chief secretary, and attorney-general, and Sir Thomas McIlwraith as treasurer, was formed. An agitation for the separation of Queensland into two or three separate colonies—mentioned as early as 1866—was very marked during this period. It took formidable shape at Townsville in 1882, the chief argument in its favour being that the north and central districts did not get a fair share of the public expenditure. Delegates were sent to London on several occasions to interview the Colonial Secretary, but success did not attend these direct appeals. Sir Samuel Griffith's Decentralization Bill of 1890, which proposed to erect separate legislatures in the three divisions with powers of local government, was a blow to separationists, and the agitation gradually disappeared.

The Labour Party in Politics, 1890 to 1900.—The decade from 1890 to 1900 was chiefly notable, apart from the accomplishment of Federation, for the rise of the Labour party as a power in politics and the gradual disappearance of the squatter as a dominant factor. In 1890 the old opponents, Sir Samuel Griffith and Sir Thomas McIlwraith, were still working side by side. The revenue for the year fell short of the estimates by half a million sterling, and a heavy accumulated deficit had to be grappled with by Parliament. Sir Thomas McIlwraith, the treasurer, proposed a dividend tax and other imposts, which were agreed to, and a Treasury Bills Act authorizing an issue of £500,000 was also passed. A Constitution Act establishing triennial Parliaments, in place of quinquennial, which had hitherto existed, also went through. In August the great maritime strike spread to Brisbane, and crippled trade and commerce for several months. In 1891 a loan for £2,500,000, which was issued in London under the auspices of the Bank of England, failed. Sir Thomas McIlwraith reflected strongly in Parliament on the conduct of the Bank of England, and the governor of the Bank wrote to Sir James Garrick, the agent-general, protesting against Sir Thomas McIlwraith's statements, and breaking off relations with the colony; but mutual explanations afterwards healed the breach.

Litigation was initiated by the London board of the Queensland Investment and Land Mortgage Company against the Queensland directors, on the ground that they had made advances without taking adequate security. The case was tried by the chief justice, Sir Charles Lilley, in 1891 and 1892, the defendants being Sir Thomas McIlwraith, Sir Arthur Palmer, then president of the Legislative Council, and Messrs F. H. Hart and E. R. Drury. The judge submitted 143 questions to the jury, and though these were answered generally in favour of the defendants, judgment was entered largely for the plaintiffs. On appeal, heard before a specially constituted court, presided over by the late Sir William Windeyer of New South Wales, this judgment was reversed, with costs. Lack of employment and a disastrous strike of bush workers paralysed the colony in this year. The strike began in January at Logan Downs station, where 200 shearers refused to sign the Pastoralists' Convention agreement. This strike was remarkable for the determined and aggressive attitude of the men, and the firm, though conciliatory, manner in which it was handled by Mr (afterwards Sir) Horace Tozer, the colonial secretary, who had to provide military forces and artillery to hold the strikers in check. The trouble lasted many months; and after it was over a farcically planned plot to seize the central district and proclaim a republic was revealed in the *Brisbane Courier*. As an outcome of this strike, "New Australia"—a settlement on communistic lines—was founded in Paraguay. About 500 bush workers, largely recruited from Queensland, joined the scheme, and sailed from Sydney in the barque *Royal Tar* in 1893, under the leadership of William Lane. The experiment failed disastrously, and in later years the Queensland Government paid the passages of many of the men back to the colony. The year 1892 was one of gloom and depression: want of money interfered with public works, and the impending stoppage of Kanaka labour and the low price of sugar almost ruined the planters. Sir Samuel Griffith then announced his conversion to the policy of continuing Kanaka labour for the sugar plantations, and also of land-grant railways. An Act was passed authorizing agreements with companies for the extension of the trunk lines on this principle; but the measure was unpopular, and no transactions under the Act are recorded. Financial depression reached its height in 1893: the salaries of ministers and civil servants were reduced, and drastic retrenchments were made in every department. In February 107 inches of rain fell at the head of the Brisbane river, and enormous losses were caused by the resulting floods; several vessels, including the Queensland Government gunboat *Paluma*, were washed into the Brisbane Botanic Gardens, and left high and dry when the waters subsided. A second flood followed hard on the heels of the first and caused further losses. Rockhampton, Bowen, Townsville, and other places also suffered severely from floods. On 13th March Sir Samuel Griffith was

gazetted chief justice, and on the 27th Mr (afterwards Sir) Hugh M. Nelson became premier and treasurer, and Sir Thomas McIlwraith chief secretary and secretary for railways. Parliament was dissolved on 3rd April, and after the general elections the ministry returned with 38 supporters, against Labour, 16, and Opposition and Independent, 18. During the month several financial institutions suspended payment, and on 15th May the Queensland National Bank closed its doors. Parliament was hurriedly summoned to deal with the financial crisis and the question of the Government funds held by the Queensland National Bank. Treasury notes, issued against coin held by the treasurer, were made legal tender throughout the colony; an issue of £1,000,000 Treasury bills to retire the Treasury notes was authorized, and a series of Acts dealing with the suspended banks were passed. To assist the unemployed, labour and co-operative communities were started, but proved failures. An impetus was given to the sugar industry by the Sugar Works Guarantee Act, which authorized the treasurer to guarantee debentures issued by companies for the erection of sugar mills and plant. In 1894 little legislation was achieved, the policy of the Government being directed towards national rehabilitation. In 1895 Sir Thomas McIlwraith left the colony for London, where he died on 17th July 1900. Sir James Garrick, agent-general, retired in 1895, and Mr Charles Shortt Dicken, who had acted as secretary to the agency since 1880, was gazetted acting agent-general, and held the position until the appointment of Sir Henry Norman as agent-general in November 1896. Mr Dicken was also acting agent-general during the interregnum which existed between the resignation of Sir Henry Norman and the appointment of Sir Horace Tozer in 1898. At the general election of 1896 the Labour party slightly improved its position. In that year a committee of investigation reported a heavy deficit in the affairs of the Queensland National Bank, and made certain recommendations. In 1897 the bank was reconstructed a second time upon terms very favourable to the institution. An Act was passed granting powers to a company to construct a railway from the rich mining district of Chillagoe to the terminus of the Cairns railway at Mareeba; at the end of fifty years the State will have the right to acquire the line. In April 1898 the Queensland-born statesman, Mr T. J. Byrnes, whose early death in the following September was lamented throughout Australia, succeeded Sir Hugh Nelson as premier. The late Mr (afterwards Sir) J. R. Dickson, Mr Robert Philp, and the late Mr J. Vincent Chataway, the latter an authority on the sugar industry, were members of this administration. On 24th October the trial of the three ex-directors of the Queensland National Bank, Messrs F. H. Hart, B. D. Morehead, and A. B. Webster, was commenced. The prosecution was instituted by the Government, on the advice of three barristers to whom the report of the committee of investigation into the affairs of the bank, which sat in 1897, was submitted. After a trial lasting 12 days, a verdict of "Not guilty" was returned. Proposals for the acquisition of 250,000 acres of land in New Guinea, made by a syndicate of London capitalists, were provisionally agreed to, but were eventually rejected, owing to a popular outcry raised in the colony and in New South Wales and Victoria.

Federation was a burning question in the neighbouring colonies during the year, but Queenslanders generally took little interest in the movement, and the colony was not represented at the Federal Convention at Melbourne when the Commonwealth Bill was passed. In 1899 Mr Dickson, who had succeeded Mr Byrnes as premier, was enlisted on the side of the "Billites," and in June of that year an Enabling Bill was passed. In September the Referendum supported the Act by the narrow majority of 7492 votes on a poll of 69,484. Towards the end of the second session the ministry narrowly escaped defeat on the Railway Standing Committees Bill, and resigned. Mr Dawson, leader of the Labour Opposition, then formed a ministry, and held office from 1st December to 7th December 1899. He was then defeated on a motion by Mr R. Philp, and resigned, and Mr Philp became premier, and was in power when Queensland joined the Commonwealth. The year was shadowed by the continuance of a terrible drought, which towards the end of 1900 became so aggravated that the revenue began to fall off, owing to decreased receipts from railways and land. In that year Mr Philp's chief policy was the passing of legislation to permit of the construction of railways by private enterprise. The Labour party offered vigorous opposition; but notwithstanding this a certain amount of progress was made. The Government appointed Dr Maxwell, an American sugar expert, to superintend the sugar industry in the colony; a State school of mines was established at Charters Towers; and the compulsory clauses of the Education Act were put in force for the first time. Another Act of importance was the establishment of a Government land bank. A powerful agitation for the extension or renewal of the leases of pastoral lands was raised, but no legislation resulted. A suggestion that Sir Samuel Griffith should retire from the chief justiceship, on a pension of £1750 a year (to be reduced by any emoluments received), to enable him to enter Federal politics, fell through. Some important discoveries of coal were made during the year, and dredging the northern rivers for gold became an established industry. Mr J. R. Dickson represented the colony in London at the conference of Federal delegates in 1900, when the final details of the Commonwealth were settled. Early in 1901 he was created K.C.M.G., but died somewhat suddenly, at Sydney, on 9th January of that year, shortly after he had been made a member of the first Federal ministry.

Alien Immigration.—The geographical position of Queensland, with almost half her territory lying within the tropics, has been fruitful in public questions bearing upon the immigration of Asiatics and South Sea Islanders. The lands lying along the northern coast are well suited for the cultivation of sugar, coffee, and other tropical produce, to grow which, profitably, cheap labour is required. The working classes of Queensland have always objected to the presence of coloured aliens, and successive Governments have legislated against indiscriminate immigration into the colony. In 1876 Governor Cairns reserved an Act imposing certain disabilities upon Chinese working on gold-fields. In that year a poll tax of £10 was imposed upon Chinese arriving. In 1884 another principle was adopted: masters of ships were only allowed to carry to Queensland ports one Chinese for every 50 registered tons, and the poll tax was increased to £30. In 1888 Queensland took the lead in summoning an intercolonial conference on Chinese immigration, the outcome of which was the adoption of uniform legislation: in the Queensland Act passed that year the main provision was that only one Chinese for every 500 registered tons should be permitted to be carried to the colony from Chinese ports. The poll tax was then abolished. This Act was also reserved, but received the Royal Assent on 5th February 1890, after slight modification had been made.

Treaty arrangements with Japan had been carried through by the Imperial Government, at the initiation of Queensland, under which the Japanese Government undertook to prevent the emigration of coolies to the colony; and a Pearl Shell Fisheries Act was passed in 1895 placing restrictions upon the acquisition of vested interests in the industry by Japanese and other aliens. At Federation eight Acts—two Imperial and six local—regulated the importation of Kanakas from the South Seas: that of 1880 was the basis of the system under which Kanakas were recruited in the islands, brought to the colony in schooners, employed there, and returned to their homes at the end of their three years' engagements. The 1884 Act confined Kanakas to field work. In December 1884 a Royal Commission was appointed, consisting of Messrs W. Kinnaird Rose, J. F. Buckland, and Hugh M. Milman, to report upon the system of recruiting Kanakas. Following the report of the Commission, which was in effect that many islanders had been recruited "by force and fraud," Sir Samuel Griffith, then premier, introduced the important Pacific Island Labourers Amendment Act of 1885, which stopped the importation of Kanakas after 1890. It was—and is—an article of faith with the working classes that white labour could be utilized for sugar cultivation. Yet from the passing of the Act the sugar industry began to decay, no fresh capital was put into it, plantations dwindled down in value 50 to 75 per cent., mills were closed, and the magnificent industry threatened to die out. Sir Samuel Griffith, being converted by these signs of the times from his position that sugar could flourish in the colony without coloured labour, issued on 12th February 1892 his "Manifesto to the People of Queensland," in which he acknowledged that to prevent the collapse of sugar-growing it was necessary to resume the immigration of Polynesians. This manifesto was the forerunner of the 1892 Act, which reintroduced Kanaka labour. After 1892 no further legislation on this subject was passed, and the recruiting of South Sea Islanders took place on a reduced scale. The Kanakas in the colony in 1900 numbered 8795, and the Chinese 10,000; the whole of the coloured aliens represented only between 4 and 5 per cent. of the population.

Land Legislation.—In Queensland's early days, with the predominance of the squatting class, the lands were freely leased in large blocks for sheep and cattle grazing. It was the squatter who furnished 50 per cent. of the public revenue with his rents, and who opened up the great interior by his pioneering enterprise. As, however, population increased, the necessity for the agriculturist arose, and it became requisite to legislate in the interests of the small holder. Successive Queensland Governments have had some of their hardest work in adapting their land legislation to the needs of the community, recent policy being to reduce large estates and place the cultivator on the soil. At separation from New South Wales the holding of land was regulated by Orders in Council, under an Imperial Act of 1846: untransferable leases of "runs" for fourteen years were issued, the minimum size of the run was measured in sheep-carrying capacity—4000 sheep being the least number, and £10 the minimum rent. The lessee was able to buy up his holding in blocks of 160 acres at a time, £1 per acre being

the minimum price, and was entitled to a renewal of his lease at its expiry. The minimum lease principle shut out the small agriculturist. The first leading Acts passed by Queensland were the Crown Lands Alienation Act of 1868, dealing with the settled districts, and the Pastoral Leases Act of 1869, dealing with the unsettled districts—these divisions were fixed by the first-named measure. The "resumption" principle was introduced by the 1868 Act: lands in the settled districts were resumed after twelve months from the passing of the measure, and lessees were granted leases of half of their holdings for ten years; the other moiety was thrown open for settlement. The 1869 Act granted new leases for twenty-one years at practically the same low rentals, but 10 per cent. was added to the rent after each period of seven years; the area of a run was fixed at from 25 to 100 square miles. This Act greatly pleased the squatters. In 1884 the Dutton Act was passed. Its importance lies in its dealings with the 1869 Act leases: on their expiry the State resumed from one-quarter to one-half of the area as Crown lands, which were thrown open to selectors, and new leases from ten to fifteen years were granted for the balance. Grazing farms (20,000 acres) and agricultural farms (1280 acres) were established. This measure was very unpopular with the squatters. With the Act of 1897 it forms the basis of the existing land regulations of Queensland. Under the 1897 Act the passing of the land into the hands of agriculturists was further marked by the creation of agricultural homesteads (160, 320, or 640 acres), grazing homesteads (20,000 acres), scrub selections (10,000 acres), and unconditional selections (1280 acres). Some of these classes of selections could be purchased right out, and all were leased at extremely moderate rates. Sales of country lands were established. Two measures were passed, in 1894 and 1897—the Agricultural Lands Purchases Acts—under which the State was authorized to purchase suitable estates of specially fertile land already alienated, to be cut up and thrown open as agricultural farms. These measures confirmed Queensland's determination to encourage agriculture. Owing to the expiration of pastoral leases and the fact that no legislation existed for their renewal for a term long enough to encourage the investment of capital, a formidable agitation prevailed in the colony, the lessees bitterly complaining of the uncertainty of their tenure. The British Australasian Society was formed in Great Britain, to protect the interests of British capital invested in the pastoral industry in Queensland. In 1900, out of the total Queensland area of 427,838,080 acres, no less than 411,793,786 acres remained in the hands of the State unalienated. (J. T. CR.)

Queenstown, a seaport, urban sanitary district, and important naval station, in the county of Cork, Ireland, on the south side of the Great Island in Cork harbour, 13 miles east-south-east of Cork by rail. Of late years the local authorities have expended large sums of money in widening the streets, providing public baths, and improving the water supply. The harbour contains three islands—Spike, the Rocky Island, and Haulbowline, where extensive docks have been erected by the Government. Population, about 9000.

Queenstown, a town of Cape Colony, in the upper valley of the Great Kei river, about midway between East London and Aliwal North, with both of which places it is connected by rail. It is well situated in the abundantly watered and fertile district between the Great Winterberg and Stormberg ranges, which was formerly inhabited by the Tambuki branch of the Ama-Xosa Kaffres. Queenstown is a prosperous agricultural centre, with a population which rose from about 2500 in 1887 to over 3000 in 1900.

Quelimane, Kilimane, or São Martinho de Quelimane, a town of Portuguese East Africa, capital of the district of Zambezia, 14 miles above the mouth of the river Bons Signaes, with anchorage in the stream in over 30 feet of water. It has a trade in copra, almonds, sesamum, indiarubber, coffee, wax, ivory, and skins, and produces rice, millet, and beans. The trade aggregates barely £200,000 per annum. Soap and oil are manufactured here. Population, 3000.

Quelpart (Chai-ju), an island used by Korea as a penal settlement, situated in 126° 10′ to 126° 57′ E., and 33° 11′ to 33° 35′ N. It is 40 miles from east to west and 17 from north to south. It rises gradually from the sea-board, is heavily wooded, and is cleared for cultivation to a height of 2000 feet. There are several crateriform hills, and Hali San (Mount Auckland) has an altitude of 6558 feet. The island is entirely volcanic, and the soil is finely disintegrated lava. Broken black lava forms the beach, and blocks of it are the universal building material. There is no good drinking water. There are no good harbours, and the only anchorage for large vessels is Tai-chong, or Yung-su, at the east end, with from 9 to 13 fathoms of water.

Population and Industries.—The officially estimated population is 100,000, Korean by race, language, and costume. There are 3 magistracies and 90 villages. The valleys and slopes are carefully cultivated in fields divided by stone walls, and produce beans, peas, sweet potatoes, "Russian turnip radish," barley, a little rice, and millet, the last being the staple article of diet. Nuts, oranges, limes, and plums are grown. Small but strong ponies are bred for export, and small cattle and pigs for home use. Apart from agriculture, the industries consist in the manufacture of fine bamboo hats and mats, and wooden combs for export and local use. For fishing the islanders use double-decked raft boats, similar to those of southern Formosa. Their lucrative pearl fisheries have been practically monopolized by the Japanese, who use proper diving apparatus. A valuable product is a species of clam, the shell of which furnishes a specially iridescent mother-o'-pearl, which the natives barter with the Japanese for inlaying lacquer. European goods are not imported, but Japanese articles find ready barter. There are no markets, and only a very few poor shops.

Capital.—Chu-song, the capital and seat of Government, a few miles from Port Pelto, has a black lava wall 25 feet high, with three gates and towers; an imposing audience-hall in Chinese style; and a great bell tower, with a fine bronze bell, sounded to drive off "evil dragons." Its population is estimated at 16,000. The governor has a hereditary army for coercive purposes. The uniform is a complete suit of mail, with a helmet, from which leather curtains fall over the shoulders. The weapons are equally antique. Pelto has ancient breakwaters for the protection of small boats, erected, many believe, by the Mongol conqueror, Khublai Khan, who in 1273 built on Quelpart 100 ships for the invasion of Japan.

Flora and Fauna.—These are scarcely yet investigated. Pines of three species, junipers, larches, oaks, maples, willows, and the *Thuja Orientalis*, have been identified. The known fauna comprise boars, bears, deer, swans, geese, pheasants, and quail. The roads are scarcely passable bridle tracks. Quelpart was introduced to European notice by the Dutchman, Hendrik Hamil, who was shipwrecked there in 1653. (I. L. B.)

Quental, Anthero de (1842–1891), Portuguese poet, was born on the island of St Michael, in the Azores, 18th April 1842. He studied at the University of Coimbra, and soon distinguished himself by unusual talent, as well as turbulence and eccentricity. He began to write poetry at an early age, chiefly, though not entirely, devoting himself to the sonnet. After the publication of one volume of verse, he entered with great warmth into the revolt of the young men which dethroned Castilho, the chief living poet of the elder generation, from his place as dictator over modern Portuguese literature. He then travelled, engaged on his return in political and socialistic agitations, and found his way through a series of disappointments to the mild pessimism, a kind of Western Buddhism, which animates his latest poetical productions. His melancholy was increased by a hopeless spinal disease, which after several years of retirement from the world, eventually drove him to suicide in his native island,

11th September 1891. Anthero stands unquestionably at the head of modern Portuguese poetry after the unrivalled João de Deus. His principal defect, in a strictly poetical point of view, is monotony—his own self is his solitary theme, and he seldom attempts any other form of composition than the sonnet. On the other hand, few poets who have chiefly devoted themselves to this form have produced so large a proportion of really exquisite work. The comparatively few pieces in which he either forgets his doubts and inward conflicts, or succeeds in giving them an objective form, are among the most beautiful in any literature. The purely introspective sonnets are less attractive, but equally finely wrought, interesting as psychological studies, and impressive from their evident sincerity. His mental attitude is well described by himself as "the effect of Germanism on the unprepared mind of a Southerner." He had learned much, and half-learned more, which he was unable to assimilate, and his mind became a chaos of conflicting ideas, settling down into a condition of gloomy negation, save for the one conviction of the vanity of existence, which ultimately destroyed him. He will live not more by the beauty of his style and diction than by the truth of self-portraiture. As a prose writer he displayed almost equal ability, but the same want of balance and sound judgment. A healthy participation in public affairs might have saved him, but he seemed incapable of entering upon any course that did not lead to delusion and disappointment. The great popularity acquired, notwithstanding, by poetry so metaphysical and egotistic is a striking testimony to the artistic instinct of the Portuguese people. Much of the charm necessarily evaporates in translation, yet Quental has been ably rendered by Mr Edgar Prestage in English and by Dr Storch in German.

(R. G.)

Querétaro-Arteaga, a state of Mexico, bounded on the N. by San Luis Potosí, on the E. and N.E. by Hidalgo, on the S.E. by Mexico, on the S. by Michoacan, and on the W. by Guanajuato. Area, 3558 square miles. Population (1879), 203,250; (1900), 228,489. The trade of the state may be estimated at about $10,000,000 (Mexican currency) a year, and consists principally of cereals, fruits, jerked meat, and mineral products. The Mexican Central Railway traverses the state, and there are numerous tramway lines. The capital, Querétaro, or Distrito del Centro, with a population of 34,576 (1895), is situated some 134 miles from the city of Mexico. Besides its commercial importance, this city is interesting historically as the birthplace of Mexican independence, and the last refuge and place of execution of the emperor Maximilian. It has fine public buildings, among which the Federal Palace and the Government Palace (both built of basalt), the Municipal Palace, the Cathedral, and the historic Iturbide Theatre should be mentioned. An excellent aqueduct, 5 miles long, supplies the city with water. Amongst other important towns are San Juan del Rio (9040 inhabitants), Landa (6324), Ahuacatlan (5929), Jalpán (5131), and Toliman, noted for its opals.

Quesada y Matheus, Jenaro de (1818–1889), 1st Marquis of Miravalles, Spanish soldier, was born at Santander, 6th February 1818. He was a son of General Vicente Quesada, a Conservative officer who was murdered and atrociously mutilated in the streets of Madrid by a revolutionary mob in the early days of Queen Isabella's reign. As Quesada belonged to an ancient family connected with the dukes of Fernan Nuñez, he was made a cornet when only six years old, was educated at the seminary for nobles, and in 1833 was promoted lieutenant in the 1st Foot Guards. He served from 1833 to 1836 against the Carlists. When his father was assassinated in 1836 he resigned, went to France, got employment in a merchant's office, and was only induced to return to the army in 1837 by his relatives, who got him a company in the guards. He distinguished himself often in the Carlist war, but his promotion was slow, and he declined to have anything to do with politics. He confined himself to his duties as a soldier, always fighting on the side of Governments against Carlist, Republican, and Progressist risings. He only became a general of division in 1853, and at the head of the Madrid garrison he fought hard in 1854 to avert the triumph of Espartero, O'Donnell, and Dulce, who publicly recognized his gallant conduct. When the war in Morocco broke out, Marshal O'Donnell gave Quesada the command of a division, which played so conspicuous a part in that campaign and at the battle of Wad el Ras that its commander was made lieutenant-general and grand cross of Charles III. He was director-general of the Civil Guard when the military rebellion of 22nd June 1866 broke out in Madrid, and after he had been wounded in the leg he remained at the head of the loyal troops until the insurgents were crushed. He did not accept any military post during the revolution until Marshal Serrano in 1874 offered him the direction of the staff, and he only accepted it after clearly stating that he was a royalist and partisan of Alphonso XII. In his long and brilliant career he never swerved from his steadfast resolve never to be mixed up in any political or military intrigues or pronunciamientos—to use his own words, "not even to restore my king." As soon as the king was restored, the Government of Señor Canovas made Quesada first general-in-chief of the army of Central Spain, and in February 1875 general-in-chief of the army of the North. With the assistance of another officer who also had never dabbled in pronunciamientos, General O'Ryan, Quesada restored discipline in the armies confronting Don Carlos, and for twelve months concerted and conducted the operations that forced the pretender to retire into France and his followers to lay down their arms. The Government confided to the marquis of Miravalles the difficult task of ruling the northern provinces for several years after the war, and he succeeded in conciliating the sympathies of the Basques and Navarrese, though the penalty of their last rising had been the loss of most of their ancient liberties or "fueros." Quesada was made marquis of Miravalles, grandee after the war, minister of war in 1883, and senator. Though he was a strict, stern disciplinarian of the old school and an unflinching Conservative, Catholic, and royalist, even his political and military opponents respected him, and were proud of him as an unblemished type of the Castilian soldier and gentleman. He died at Madrid, 19th January 1889, and was given full military honours.

(A. E. H.)

Quetta, a district and town of Baluchistan, rose to prominence in 1876, when Sir Robert Sandeman founded a residency there, and first represented the Government of India as the practical ruler of Baluchistan. The name is a variation of the word *kwat-kot*, signifying a fortress, and the place was locally known as Shál Kot till adopted officially as Quetta. The name is doubtless derived from the fortified "Miri" or mound, which is the dominant position on the plain whereon the present fort now stands, and beneath which the old town clustered formerly. This prominence is doubtless one of those dead mud volcanoes with which Baluchistan abounds. There are some on the Baluch coast still in active operation. The cantonment and civil station of Quetta, which now cover an area of many square miles, and are ever extending their borders, stand in the open plain at a height of about 5500 feet above sea-level, within a ring of gigantic mountain heads (such

as Takatu, Murdar, and Chiltán) which overlook it from a height of over 11,000 feet. To the north-west the view is open across the base of the Peshin valley to the Khojak and Kandahar. Southwards is the open valley leading to the Bolan Pass, traversed by the railway. North of Quetta is the open plain leading to Peshin and the Harnai, also traversed by the Sibi-Peshin line of railway, which passes through the fortifications. These defensive works, stretching from the base of Takatu to the foot of the Mashelak hills on the west, bar the way to advance from the Khojak. The actual line of valley which contains Quetta and the Bolán was originally rented from the Khan of Kalát on terms which were changed in 1882 to a quit-rent of 25,000 rupees per annum, and a further compensation of 30,000 in lieu of transit duties in the Bolán. This perpetual leasehold was afterwards extended so as to include Nushki and give the Government of India the command of the trade route to Sistan. The Quetta district is now administered, together with the assigned districts of Peshin, Tal Chotrall, and Sibi (assigned by the treaty of Gandamak as being nominally Afghan territory) by a regular staff of civil officials. During the last quarter of the 19th century Quetta grew from a dilapidated group of mud buildings, with an inferior bazaar and a few scattered remnants of neglected orchard cultivation, into one of the most popular stations of the Indian service. A residency was followed by a club-house, and by public buildings of all descriptions, schools, hospitals, and a first-class market-place in the civil station. Drainage, irrigation by artesian wells, and railways followed the extension of military occupation. The Yorktown quarter, the high, level end of Quetta, sprang into existence, taking its name from its first occupants, the Yorkshire Light Infantry. This rapid evolution has been chiefly due to the energy and foresight of Sir Robert Sandeman, with whose name the history of Quetta must be ever associated. Quetta is already the trade mart for western Afghanistan, eastern Persia, and much of central Asia.

Indian Survey Reports, 1878 to 1898. Calcutta.—THORNTON. *Life of Sir Robert Sandeman.* London, 1896. (T. H. H*.)

Quezaltenango, capital of a department of Guatemala, Central America, and the second town of the republic, is situated on the northern slope of the Cerro Quemado volcano, on a high plateau (7700 feet), watered by the Samala, 75 miles west-north-west of Guatemala, and 35 north-east of its port, Champerico. A railway is projected to connect it with San Felipe, the actual terminus of the line which runs inward from Champerico. The town is the centre of the trade (in coffee, sugar, and cereals) of western Guatemala, and it has also cotton and woollen manufactures. There are several important educational establishments, including schools of law and of medicine, a school of art, and higher-class schools for boys and girls. Under the name of Xenahu or Xelaluh it was an Indian town before the conquest. From 1838 to 1840 it was the capital of the three departments of the plateau —Quezaltenango, Solola, and Totonicapum—which during those years combined to form an independent republic. Population, about 27,000, a large proportion being Indians.

Quilon, a seaport town of India, on the Malabar coast, in the state of Travancore; situated in 8° 53′ N. and 76° 36′ E. Population (1891), 15,375. Formerly a British cantonment; now the headquarters of the Travancore army, with a subsidiary battalion. There is a cotton mill, with 25,000 spindles, employing 600 hands. It is proposed to construct a railway across the hills from Tinnevelly.

Quincy, a city of Illinois, U.S.A., capital of Adams county. It is situated in 39° 55′ N., and 91° 25′ W., on the east bank of the Mississippi river, in the western part of the state, at an altitude of 481 feet. It is built largely on the river bluffs, is regularly laid out, is divided into seven wards, has a water-supply pumped from the river, is well sewered, and its business streets are paved with brick. Three railways enter the city, the Chicago, Burlington, and Quincy, the Omaha, Kansas City, and Eastern, and the Wabash; and these, with boats on the river, give it a large trade. It has prominence as a manufacturing place. In 1890 there were 394 manufacturing establishments, employing 5110 hands, and having a total capital of $6,554,810. The product was valued at $10,395,102. The principal items were flour, foundry and machine-shop products, carriages and waggons, and packed meats. In 1899 the assessed valuation of real and personal property was $4,620,353, indicating a very low rate of assessment. The net debt of the city was $1,148,415, and the rate of taxation was $77.20 per $1000. Population (1890), 31,494; (1900), 36,252, of whom 4961 were foreign-born and 2029 negroes. There were 11,543 persons of school age (5 to 20 years). Of 10,276 males 21 years of age and over, 391 were illiterate (could not write).

Quincy, a city of Norfolk county, Massachusetts, U.S.A. It is on the south shore of Boston bay, a few miles south-east of Boston, in the eastern part of the state. It was incorporated as a city in 1888. It is in great measure a residential suburb of Boston, but is noted also for its quarries of Quincy marble, which is widely used as a building stone, and for its manufacture of boots and shoes. It is on a branch of the New York, New Haven, and Hartford Railroad. Population (1890), 16,723; (1895), 20,712; (1900), 23,899, of whom 7662 were foreign-born.

Quito, the capital of Ecuador, Central America, situated on the Andine plain, 9300 feet above sea-level, 165 miles north-east of Guayaquil, to which a railway is under construction. At present trade is still hampered by the difficulties of communication. The exports are chiefly hides and indiarubber. The native manufactures include saddles, tanned leather, shoes, ponchos, woollen and cotton cloth, sandals, common sacking, blankets, wood-carvings, coarse matting, coarse woollen carpets, and also superior hand-made carpets. Electric lighting was introduced in 1898. The population is about 80,000.

Rabah Zobeir (—— –1900), the conqueror of Bornu (an ancient sultanate on the western shores of Lake Chad, included since 1890 in British Nigeria), was a half-Arab, half-Negro chieftain. He was originally a slave of Zobeir Pasha (*q.v.*). In 1879, Zobeir being in Egypt, his son Suleiman and Rabah were in command of Zobeir's forces in the Bahr-el-Ghazal. They persisted in slave-raiding, and denied the Khedive's authority, and Colonel C. G. Gordon sent against them Romulous Gessi Pasha. Gessi captured Suleiman and routed Rabah, who in July 1879 fled westward with some seven hundred Bazingirs (black slave soldiers). During the next fourteen years Rabah overran various states of Central Africa, defeating the sultan of Wadai and establishing himself in Bagirmi, a state south-east of Lake Chad. In 1893 Rabah overthrew the sultan of Bornu. He could not have been

successful in this campaign but for the very strong discontent against the reigning family that had existed for some years in Bornu. To the British, represented by the Royal Niger Company, Rabah gave comparatively little trouble. During 1894–95 he continually (but unavailingly) asked the Company's representatives at Yola and Ibi to supply him with gunpowder. Rabah then tried threats, and in 1896 all communication between him and the Company ceased. Early in 1897 he began an advance in the direction of Kano, the most important city in the Fulani Empire. The news of the crushing defeat by Sir George Goldie of the Fulahs at Bida, and of the capture of Ilorin, induced Rabah to return to Bornu. He gave the British no further trouble, but turned his attention to the French. M. Gentil had in this same year (1897) reached Lake Chad, *viâ* the Congo and Bagirmi, and had installed a French resident with the sultan of Bagirmi. Years before (in 1891) Rabah had killed M. Paul Crampbel, who had led an expedition towards Lake Chad, and now, as soon as M. Gentil had withdrawn, Rabah again fell upon Bagirmi, and forced sultan and resident to flee. In 1899 the French sent an expedition to reconquer the country, but at first they were unsuccessful. In the summer of 1899 Rabah attacked and routed the French advanced post, held by Naval-Lieutenant Bretonnet, and the latter was killed. In October following another battle was fought, in which the French, under Captain Robillot, completely defeated Rabah, who retreated north-east towards Wadai. Gathering a fresh army, he returned to Bagirmi and joined issue with the French a third time. In a battle fought in April 1900 Rabah was slain and his host defeated. The chieftain's head was cut off and taken to the French camp. In this engagement Major Lamy, the French commandant, also lost his life.

The French continued the campaign against Rabah's sons, two of whom were killed. Rabah had left instructions that if his army was finally defeated by the French, his successor should return to Bornu and make friends with the British. Rabah's third son, Fader-Allah, accordingly threw himself entirely upon British protection. He made a favourable impression, and it was contemplated to recognize him as sultan of Bornu. However, in the later part of 1901 Fader-Allah, who had 2500 riflemen, again made aggressive movements against the French. In retaliation, Captain Dangeville pursued him into British territory. A battle was fought at Gujiba, Fader-Allah being defeated. He fled mortally wounded, and died the same night, being buried in the bed of a small river, the course of which had been diverted for the purpose. In consequence of these occurrences General Lugard, High Commissioner of Northern Nigeria, despatched to Bornu, in January, 1902, a force under Colonel Morland, the result being the effective establishment of British rule in that country. The French force which had remained in Bornu retired as Colonel Morland approached Lake Chad. (F. R. C.)

Rabat (*Rîbât el Fateh*) is only of importance in these days as one of the Moorish ports open to foreigners, which is not the case with its older *vis-à-vis*, Salli. A few merchants, some of whom hold consular appointments, and missionaries, form a small foreign colony; but the growth of trade is slow, as the bar in the river hampers the shipping. Exports: 1896, £31,819; 1897, £42,877; 1898, £42,536; 1889, £22,457; 1900, £20,071. Imports: 1896, £140,064; 1897, £110,488; 1898, £111,861; 1899, £110,384; 1900, £95,440. Shipping: 1897, 58,349 tons; 1898, 541,526 tons; 1899, 65,324 tons; 1900, 37,758 tons. Population, probably 30,000.

Racine, a city of Wisconsin, U.S.A., capital of Racine county. It is situated in 42° 43′ N., and 87° 47′ W., on the shore of Lake Michigan, 62 miles north of Chicago and 23 miles south of Milwaukee, on the Chicago, Milwaukee, and St Paul and the Chicago and North-Western railways, at an altitude of 627 feet. It is regularly laid out on a level site, divided into seven wards, and has a water-supply from the lake. It has a good harbour, and a share of the lake commerce. Its manufactures in 1900 were carried on by 252 establishments, with a total capital of $16,753,215. They employed 6785 hands, and the product was valued at $12,502,796. The principal articles of manufacture are agricultural implements, carriages and waggons, for which Racine is widely known. These articles form not far from one-half the value of all the manufactured goods. Population (1890), 21,014; (1895), 24,889; (1900), 29,102, of whom 9242 were foreign-born.

Racing. See HORSERACING.

Radautz, a town in the Austrian duchy of Bukovina. Population (1890), 12,895; (1900), 14,343 (estimated, 68 per cent. Germans, 25 per cent. Rumanians, 4 per cent. Poles, and 3 per cent. Ruthenians. There is a German upper gymnasium and a Protestant church. The Government stud contains over 1400 horses.

Radcliffe, a town, urban district (1894), and parish, in the Radcliffe-cum-Farnworth parliamentary division of Lancashire, England, 7 miles north-west of Manchester by rail. Technical schools were erected in 1896, and a public swimming bath was opened in 1899. Dyeing, paper-making, iron founding, and machine-making have become important industries. Population of urban district (1881), 16,267; of extended area (1891), 24,972; (1901), 25,368: of the parliamentary division (1881), 63,086; (1891), 72,931; (1901), 78,298.

Radeberg, a town of Germany, on the Grosse Röder, 8 miles by rail north-east by east of the town and in the circle of Dresden, kingdom of Saxony. There are important glass-works. Near by is a dairy and cheese institute. Population (1890), 8740; (1900), 12,918.

Radiation, Theory of.—1. The foundation of this subject is the principle, arrived at independently by Balfour Stewart and Kirchhoff about the year 1858, that the constitution (§ 6) of the radiation which pervades an enclosure, surrounded by bodies in a steady thermal state, must be a function of the temperature of those bodies, and of nothing else (see RADIATION, *Ency. Brit.* vol. xx.). It was subsequently pointed out by Stewart (*Brit. Assoc. Report*, 1871) that if the enclosure contains a radiating and absorbing body which is put in motion, all being at the same temperature, the constituents of the radiation in front of it and behind it will differ in period on account of the Doppler effect, so that there will be an opportunity of gaining mechanical work in its restoration to a uniform state; there must thus be some kind of thermodynamic compensation, which might arise (see RADIATION, *Ency. Brit.* vol. xx.) either from æthereal friction, or from work required to produce the motion of the body against pressure exerted on it by the surrounding radiation. The hypothesis of friction is now excluded in ultimate molecular physics, while the thermodynamic bearing of a pressure exerted by radiation has been more recently developed by Bartoli and Boltzmann (1884), and combined with that of the Doppler effect by W. Wien (1893).

The original reasoning of Stewart and Kirchhoff rests on the dynamical principle, that by no process of ordinary reflexion or transmission can the period, and therefore the wave-length, of any harmonic constituent of the radiation be changed; each constituent remains of the same wavelength from the time it is emitted until the time it is again absorbed. If we imagine a field of radiation to be enclosed within perfectly reflecting walls, then, provided there is no material substance in the field which can

radiate and absorb, the constitution of the radiation in it may be any whatever, and it will remain permanent. It is only the presence of material bodies that by continued emission and absorption can transform it towards the unique constitution which corresponds to their temperature. We can define the temperature of a uniform field of radiation, of this special constitution and travelling in all directions indifferently, as the temperature of the material bodies with which it would thus be in equilibrium. Further, the mutual independence of the various constituents of any enclosed field of radiation allows us to assign a temperature to each constituent, such as the part involving wave-lengths lying between λ and $\lambda+\delta\lambda$; that will be the temperature of a material system with which this constituent by itself is in equilibrium of emission and absorption. But to reason about the temperature of radiation in this way we must be sure that it completely pervades the space, and has no special direction; the question of the temperature of a directed wave-train, such as a beam of light, will come up later. The temperature of each constituent in a region of undirected radiation is thus a function of its wave-length and its intensity alone. It is the fundamental principle of thermodynamics, that temperatures tend to become uniform. In the present case of a field of radiation this equalization cannot take place directly between the various constituents of the radiation that occupy the same space, but only through the intervention of the emission and absorption of material bodies; the constituent radiations are virtually partitioned off adiabatically from direct equilibrium. Thus in discussing the transformations of temperatures of the constituents of radiation we are really reasoning about the activity of material bodies that are in thermal equilibrium with those constituents; and the theoretical basis of the idea of temperature, as depending on the fortuitous element in molecular motions, is preserved.

2. *Mechanical Pressure of Undulatory Motions.*—Consider a wave-train of any kind, in which the displacement is $\xi = a \cos m(x+ct)$ so that it is propagated in the direction in which x decreases; let it be directly incident on a perfect reflector travelling towards it with velocity v, whose position is therefore given at time t by $x = vt$. There will be a reflected train given by $\xi' = a' \cos m'(x-ct)$, the velocity of propagation c being of course the same for both. The disturbance does not travel into the reflector, and must therefore be annulled at its surface; thus when $x = vt$ we must have $\xi + \xi' = 0$ identically. This gives $a' = -a$, and $m'(c-v) = m(c+v)$. The amplitude of the reflected disturbance is therefore equal to that of the incident one; while the wave-length is altered on the ratio $\dfrac{c-v}{c+v}$, which is approximately $1-2v/c$ when v/c is small, and is thus in agreement with the usual statement of the Doppler effect. The energy in the wave-train being half potential and half kinetic, it is given by the integration of $\rho(d\xi/dt)^2$ along the train, where ρ represents density. In the reflected train it is therefore augmented, when equal lengths are compared, in the ratio $\left(\dfrac{c+v}{c-v}\right)^2$; but the length of the train is diminished by the reflexion in the ratio $\dfrac{c-v}{c+v}$; hence on the whole the energy transmitted per unit time is increased by the reflexion in the ratio $\dfrac{c+v}{c-v}$. This increase per unit time can arise only from work done by the advancing reflector against pressure exerted by the radiation. That pressure, per unit surface, must therefore be equal to the fraction $\dfrac{2}{c-v}$ of the energy in a length $c+v$ of the incident wave-train; thus it is the fraction $\dfrac{c^2-v^2}{c^2+v^2}$ of the total density of energy in front of the reflector, belonging to both the incident and reflected trains. When v is small compared with c, this makes the pressure equal to the density of vibrational energy, in accordance with Maxwell's electrodynamic formula.

The argument may be illustrated by the transverse vibrations of a tense cord, the reflector being then a lamina through a small aperture in which the cord passes; the lamina can thus slide along the cord and sweep the vibratory motion in front of it. In this case the force acting on the lamina is the resultant of the tensions T of the cord on the two sides of the aperture; this resultant is $\frac{1}{2}\mathrm{T}d(\xi+\xi')^2/dx^2$, which, when v/c is small, is an oscillatory force of amount $2\rho(d\xi/dt)^2$, whose time-average agrees with the value above obtained.

When it is a case of transverse waves in an elastic medium, reflected by an advancing obstacle, the origin of the working pressure is not so obvious, because we cannot easily formulate a mechanism for the advancing reflector like that of the lamina above employed. In the case of light-waves we can, however, imagine an ideal material body, with very small molecules, that would reflect them with the same perfection as a metallic mirror reflects the longer Hertzian waves. The pressure will then be represented, as in the case of the latter waves, by the mechanical forces acting on the screening oscillatory electric current-sheet which is induced on the surface of the reflector. The displacement represented above by ξ, which is annulled at the reflector, may then be taken to be either the tangential electric force or the normal component of the vector whose velocity is the magnetic force. The latter interpretation is theoretically interesting, because that vector, which is the dynamical displacement in electron-theory, usually occurs only through its velocity. The general case of oblique incidence can be treated on similar lines.

The usual formula for the pressure of electric radiation is derived from a theory, namely, that of the ordinary electrodynamic equations, which considers the velocity of the matter, or rather of the electrons associated with it, to be so small compared with that of radiation that the square of the ratio of these velocities can be neglected. The formula above obtained is of general application, and shows that for high values of v the pressure must fall off. It has been urged as an objection to the thermodynamic reversibility of a ray (§ 8) that the work of the radiant pressure exerted at its front is lost, as there is no obstacle to sustain it; but on an obstacle moving with the velocity of the wave-front the pressure would vanish, so that this objection does not hold.

In every such case of an advancing perfect reflector the aggregate amplitude of the superposed incident and reflected wave-trains, of different wave-lengths and periods, will be represented by

$$\xi + \xi' = 2a \sin \frac{mv}{c-v}\left(x - \frac{c^2}{v}t\right) \sin \frac{mc}{c-v}(x - vt);$$

thus the appearance presented will be that of a train of waves each of length $2\pi/m \cdot (1-v/c)$, and travelling with the velocity v of the reflector, which is at one of the nodes of the train. This slowly travelling wave-train corresponds to the stationary train which would be produced by a stationary perfect reflector; but the amplitude is now a varying quantity which, once uniform vibration has been fully established along any path, may itself be described as running on after the manner of a superposed wave-train of very great wave-length $2\pi/m \cdot (c/v - 1)$ and of

very great velocity c^2/v. A somewhat similar state of things arises when a wave-train is incident on a stationary reflector very nearly normally, as may sometimes be seen with incoming rollers along a shelving beach; the visible disturbance at a reflecting ridge, arising from a single wave-crest, then rushes along the ridge at a speed at first sight surprising, as it is enormously in excess of the speed possible for any simple train of waves.

3. *Wien's Law.*—Let us consider a spherical enclosure filled with radiation, and having walls of ideal perfectly reflecting quality so that none of the radiation can escape. If there is no material body inside it, any arbitrarily assigned constitution of this radiation will be permanent. Let us suppose that the radius a of the enclosure is shrinking with extremely small velocity v. A ray inside it, incident at angle ι, will always be incident on the walls after the successive reflexions at the same angle, except as regards a negligible change due to the motion of the reflector (§ 2); and the length of its path between successive reflexions is $2a \cos \iota$. Each undulation on this ray will thus undergo reflexion at intervals of time equal to $2ac^{-1} \cos \iota$, where c is the velocity of light, and it is easily verified that on each reflexion it is shortened by the fraction $2vc^{-1} \cos \iota$ of itself: thus in the very long time T required to complete the shrinkage it is shortened by the fraction vTa, which is $\delta a/a$ where δa is the total shrinkage in radius, and is independent of the value of ι. The wave-length of each undulation in the radiation inside the enclosure is therefore reduced in the same ratio as the radius. Now suppose that the constitution of the enclosed radiation corresponded initially to a definite temperature. During the shrinkage thermal equilibrium must be maintained among its constituents; otherwise there would be a running down of thermal energy if material radiating bodies are present, which would be superposed on the mechanical operations belonging to the shrinkage, and the process would not be reversible. Such a state of affairs is not possible, for it would land us in processes of the following type. Expand the enclosure, gaining the mechanical work of the radiant pressure against its walls, whatever that may be. Then equalize the intensities of the constituent radiations to those corresponding to a common temperature, by taking advantage of the absorptions of material bodies at the actual temperatures of these radiations; when this is done, as it may actually be to some extent by aid of the sifting produced by partitions which transmit some kinds of radiation more rapidly than others, a further gain of work can be obtained at the expense of the radiant energy. Then contract the remaining radiant energy to its previous volume, which requires an expenditure of less work on the walls of the enclosure than the expansion of the greater amount of radiation originally afforded; and, finally, gain still more work by again equalizing the temperatures of its constituents. The energy now remaining, being of smaller amount and under similar conditions, must have a temperature lower than the initial one. This process might be repeated indefinitely, and would violate Carnot's principle by deriving an unlimited supply of mechanical work from thermal sources at a uniform temperature.

Thus, independently of any knowledge of the intensity of the mechanical pressure of radiation, or indeed of whether such a pressure exists at all, it is established that the shrinkage of the enclosure must directly transform the contained radiation to the constitution which corresponds to some definite new temperature. Now we have seen that the wave-lengths of its constituents are all reduced in the same ratio by this process. If, then, we can prove that the intensities of these constituents are also all changed in a common ratio by the reflexions at the shrinking envelope, it will follow that the distributions of the radiation among the various wave-lengths are, at these two temperatures, and therefore at any two temperatures, homologous, so that the intensity curves, after the wave-lengths in one of them have been reduced in a ratio depending definitely on the two temperatures, differ only in the absolute scale of magnitude of the ordinates.

This procedure modifies Wien's argument by employing a uniformly shrinking spherical enclosure. If the enclosure is not spherical, the angles of incidence at successive reflexions of the same ray will differ by finite amounts; we must then estimate the average effect of the shrinkage. In the form of enclosure here employed all rays are affected alike, while by the principle of Stewart and Kirchhoff what is established for any one form is of general validity.

4. *Pressure of Natural Radiation.*—The question reserved above has now to be settled. At first sight it might have appeared that the reflexion is perfect; but, as has been seen in § 2, the advancing perfect reflector does work against the pressure of the radiation, and this work must be changed into radiant energy and thus go to increase the intensity of the reflected ray. Considering electric radiation incident at angle ι, the tangential electric force is annulled at the reflector; hence the amplitude of the vibration is conserved on reflexion, though its phase is reversed when the electric vibration is in the plane of incidence. As already seen, the wave-length is shortened approximately by the fraction $2vc^{-1}\cos\iota$ in each reflexion; thus, as in § 2, the energy transmitted per unit time is increased in the same ratio, and allowing for the factor $\cos \iota$ of foreshortening, there is therefore a radiant pressure equal to the total density of radiant energy in front of the reflector multiplied by $\cos^2\iota$. This argument, being independent of the wave-length, applies to each constituent of the radiation separately; thus their energies are all increased in the same ratio by the reflexion, as was to be proved. When we are dealing with the natural radiation in an enclosure, which is distributed equally in all directions, this factor $\cos^2\iota$ must be averaged; and we thus attain Boltzmann's result that the radiant pressure is one-third of the density of radiant energy, this statement holding good as regards each constituent of the natural radiation taken separately.

5. *Adiabatic Relations.*—Consider the enclosure filled with radiation of energy-density E at volume V, of any given constitution but devoid of special direction, and let it be shrunk to volume $V - \delta V$ against its own pressure; if the density thereby become $E - \delta E$, the conservation of the energy requires

$$EV + \tfrac{1}{3}E\delta V = (E - \delta E)(V - \delta V),$$

so that $\tfrac{4}{3}E\delta V + V\delta E = 0$, or E varies as $V^{-\frac{4}{3}}$.

Again—but now with a restriction to radiation of one wave-length or else of uniform temperature—the performance of this mechanical work $\tfrac{1}{3}E\delta V$ has changed the energy of radiation EV from the state that is in equilibrium of absorption and emission with a thermal source at temperature T to the state in equilibrium with an absorber of some other temperature $T - \delta T$, and that in a reversible manner; thus by Carnot's principle

$$\tfrac{1}{3}E\delta V/EV = -\delta T/T,$$

so that T varies as $V^{-\frac{1}{3}}$, or inversely as the linear dimensions when the enclosure is shrunk uniformly.

Combining these results, it appears that E varies as T^4; this is Stefan's empirical law for the complete radiation corresponding to the temperature, established on these lines by Boltzmann. Starting from the principle that this radiation must be a function of the temperature alone, this adiabatic process has in fact given us the form of the function. These results cannot, however, be extended without modification to each separate constituent of the

complete radiation, because the shrinkage of the enclosure alters its wave-length and so transforms it into a different constituent.

6. *Law of Distribution of Energy.*—The effect of compressing the complete radiation is thus to change it to the constitution belonging to a certain higher temperature, by shortening all the wave-lengths by the proportion of one-third of the compression by volume, the temperature being in fact raised by the same proportion; at the same time increasing in a uniform ratio the amounts corresponding to each interval $\delta\lambda$, so as to get the correct total amount of energy for the new temperature. In the compression each constituent alters so that $T\lambda$ remains constant, and the energy $E_\lambda\delta\lambda$ in the range $\delta\lambda$ in other respects changes as a function of T alone. Hence generally $E_\lambda\delta\lambda$ must be of form $F(T)f(T\lambda)\delta\lambda$. But for each temperature $\int_0^\infty E_\lambda\delta\lambda$ is equal to E and so varies as T^4, by Stefan's law; that is,

$$T^{-1}F(T)\int_0^\infty f(T\lambda)d(T\lambda)\propto T^4,$$

so that $T^{-1}F(T)\propto T^4$. Thus, finally, $E_\lambda\delta\lambda$ is of form $AT^5f(T\lambda)\delta\lambda$ or $A\lambda^{-5}\phi(T\lambda)\delta\lambda$, which is Wien's formula, including nearly all that has hitherto been established theoretically on this subject.

7. *Transformation of a Single Constituent.*—It is of interest to follow out this adiabatic process for each separate constituent of the radiation, as a verification, and also in order to ascertain whether anything new is thereby gained. To this end let now $E(\lambda,T)\delta\lambda$ represent the intensity of the radiation between λ and $\lambda+\delta\lambda$ which corresponds to the temperature T. The pressure of this radiation, when it is without special direction, is in intensity one-third of this; thus the application of Carnot's principle shows, as before, that in adiabatic compression $T\propto V^{-\frac{1}{3}}$, so that a small linear shrinkage in the ratio $1-x$ raises T in the ratio $1+x$. We have still to express the equation of energy. The vibratory energy $E(\lambda,T)\delta\lambda.V$ in volume V, together with the mechanical work $\frac{1}{3}E(\lambda,T)\delta\lambda.3xV$, yields the vibratory energy

$$E\{\lambda(1-x),\ T(1+x\}\delta\lambda(1-x).V(1-3x);$$

thus, writing E for E_λ or $E(\lambda, T)$ we have, neglecting x^2,

$$E(1+x)=(E-x\lambda\frac{dE}{d\lambda}+xT\frac{dE}{dT})(1-4x),$$

so that

$$5E+\lambda\frac{dE}{d\lambda}-T\frac{dE}{dT}=0,$$

a partial differential equation of which the integral is

$$E=A\lambda^{-5}\phi(T\lambda),$$

the same formula as was before obtained.

This method, treating each constituent of the radiation separately, has in one respect some advantage, in that it is necessary only to postulate an enclosure which totally reflects that constituent, this being a more restricted hypothesis than an absolutely complete reflector.

To determine theoretically the form of the function ϕ we must have some means of transforming one type of radiation into another, different in essence from the adiabatic compression already utilized. The condition that the entropy of the independent radiations in an enclosure is a minimum when they are all transformed to the same temperature with total energy unaltered, is already implicitly fulfilled; it would thus appear that any further advance must involve (§ 11) the dynamics of the radiation and absorption of material bodies.

8. *Temperature of an Isolated Ray.*—The temperature of each independent constituent of a radiation has here been taken to be a function of the intensity E_λ, where $E_\lambda\delta\lambda$ is the energy per unit volume in the range between wave-lengths λ and $\lambda+\delta\lambda$; the condition is, however, imposed that this radiation is indifferent as to direction. When a beam of radiation travels without loss in a definite direction across a medium, its form varies as it progresses; but it is reversible inasmuch as it can be turned back at any stage, or concentrated without loss, by perfect reflectors. If the energy of the beam has a temperature, its value must therefore remain constant throughout the progress of the beam, by the principle of Carnot. Now by virtue of a relation in geometrical optics, which on a corpuscular theory would be one aspect of the fundamental dynamical principle of Action, the cross-section δS at any place on the beam, and the conical angle $\delta\omega$ within which the directions of its rays are there included, are such that the value of $V^{-2}\delta S\delta\omega$ is conserved along the beam, V being the velocity of propagation of the undulations. If we represent the amount of radiant energy transmitted per unit time across the section δS of the beam by $I\delta S\delta\omega$, it will follow that in passing along the beam its intensity of illumination I varies as V^{-2}, or as the square of the index of refraction, provided there is no loss of energy in transmission. This condition requires that changes of index shall be gradual, otherwise there would be loss of energy by partial reflexions; in free æther I is constant along the beam. The volume-density of the energy in any part of the directed beam is $V^{-1}I\delta\omega$; it is thus inversely as the angular concentration of the rays and directly as the cube of the index of refraction. Now we may consider this beam, of aggregate intensity $I\delta S\delta\omega$, to form an elementary filament of the radiation issuing in the direction of the normal from a perfect radiator. As such a body absorbs completely and therefore radiates equally in all directions in front of it, the total intensity of radiation from its element of surface δs is $\delta s\int I\cos\theta d\omega$, or $\delta s.\pi I$, while the volume-density of the total advancing and receding radiation in front of it is $2V^{-1}\int Id\omega$, and therefore $4\pi V^{-1}I$. If we take $I\delta\lambda$ to represent the intensity between wave-lengths λ and $\lambda+\delta\lambda$, this density is the quantity E_λ of which the temperature of the radiator is a function. Thus the quantity I, which optically is a measure of the brightness of the beam, and is conserved along it to the extent that μ^2I is the same from whichever of its cross-sections the beam is supposed to be emitted, also determines its temperature, the latter being that of an enclosure filled with undirected radiation of the same range $\delta\lambda$ and of density $E_\lambda\delta\lambda$ given by $E_\lambda=4\pi V^{-1}I$, where V is the velocity of radiation in the enclosure. When a beam of radiation travels without suffering absorption, its temperature thus continues to be that of its source multiplied by the coefficient of emission of the source for that kind of radiation, this coefficient being less than unity except in the case of a perfect radiator; but when its intensity I falls by δI in any part of its path owing to absorption or other irreversible process, this involves a further fall of temperature of the energy of the beam and a rise of entropy which can be completely determined when the relation connecting $\mu^{-3}E_\lambda$ with T and λ is known. Any directed quality in radiation increases its effective temperature. Splitting a beam into two at a refracting surface diminishes the temperature of each part. The direct solar radiation falling on the Earth is almost completely convertible into mechanical effect on account of its very high temperature; there seems ground for believing that certain constituents of it can actually be almost wholly turned to account by the green leaves of plants. But the same solar radiation, when broken up into diffused sky light, which has no definite direction, has fallen into equilibrium with a much lower temperature, through loss of its reversibility. It has been remarked that the temperatures of the planets can be roughly compared by means of this principle, if

their coefficients of absorption of the solar radiation are assumed; that of Neptune comes out below $-200°$ C., if we suppose that it has no internal heat.

To obtain dynamical precision in this discussion an exact definition of the narrow beam such as is usually called a ray is essential. It can be specified as a narrow filament of radiation, which may be isolated within an infinitely thin, impermeable, bounding tube without thereby producing any disturbance of the motion. If either the tube or the surrounding radiation were not present to keep the beam in shape, it would spread sideways, as in optical diffraction. But the function of the tube is one of pure constraint; thus by Poynting's law of energy-flux the change of energy-content of a given length of the tube is represented by energy flowing into it at the end where the radiation enters, and leaving it at the other end, but with no leakage at the sides.

9. *Temperature of the Sun.*—The mean temperature of the radiating layers of the Sun may be estimated from Stefan's law, by computing the intensity of the radiation at his surface from that terrestrially observed, on the basis of the law of inverse squares; the result is about 6500° C. The application of Wien's law, which makes the wave-length of maximum energy vary inversely as the temperature, for the case of a perfectly radiating source, gives a result 5500° C. These numbers will naturally differ because (i.) the Sun is not a perfect radiator, the constitution of his radiation in fact not following the law of that of a black body, (ii.) the various radiating layers have different temperatures, (iii.) the radiation may be in part due to chemical and electrical causes, and in so far would not be determined by the temperature alone. The fair agreement of these two estimates indicates, however, that the radiation is largely regulated by the temperature, that the layers from which the main part of it comes are at temperatures not very different, and that not very much of the complete radiation established in these layers and emitted from them is absorbed by the overlying layers.

10. *Fluorescence.* — When radiation of certain wave-lengths falls on a fluorescent body, it is largely absorbed, but in such manner as directly to excite other radiation of different type which is emitted in addition to the true temperature-radiation of the body. The distinction involved is that the latter radiation is spontaneously convertible with the heat of the absorbing body at its own temperature, without any external stimulus or compensation: it is, in fact, on the basis of this convertibility that the thermodynamic relations of the temperature-radiation have been established. According to the experimental law of Stokes, the wave-lengths of the fluorescent radiation are longer than those of the radiation which excites it. If the latter were directly transformed, in undiminished amount, into the fluorescent kind, this is what would be expected. For such a spontaneous change must involve loss of availability; and, beyond the wave-length of maximum energy in the spectrum, the temperature of a given density of radiation is greater the shorter its wave-length, as it is a function of that density and the wave-length alone, such that greater density always corresponds to higher temperature. But it would appear that the opposite should be the case for radiation of long wave-lengths on the other side of the maximum, in which the tendency would thus be for spontaneous change into shorter waves; this may perhaps be related to the fact that at lower temperatures the lines of longer wave-lengths in spectra often come out brighter. The principle does not, however, have free play in the present case, even when the incident radiation is diffused and so has not the abnormally high temperature associated with a directed beam (§ 8), since part of it might be degraded into low-temperature heat, or there might be other compensation of chemical type for any abnormally high availability that might exist in the fluorescent radiation. It has been found that fluorescent radiation, showing a continuous or banded spectrum, can be excited in many gases and vapours. A milky phosphorescence of considerable duration is produced in vacuum tubes, containing oxygen or other complexly constituted gases, by the electric discharge.

11. *Entropy of a Ray.*—If each definitely constituted beam of radiation has its own temperature and everything is reversible as above, a question arises as to the location of the process of averaging which enters into the idea of temperature. The answer can depend only on the fact, that although the beam is definite as to wave-length and intensity, yet it is far from being a simple wave-train, in that it is constituted of trains of limited lengths and various phases and polarizations, coming from the separate radiating molecules. When such a beam has once emerged, it travels without change, and can be reflected back intact to its source, and is in so far reversible; but when it has arrived there, the molecules of the source will have changed their positions, and it cannot be wholly reabsorbed in the same manner as it was emitted. There must thus be some feature in the ultimate averaged constitution of the beam, emitted from a body in the definite steady state of internal motion determined by its temperature, which adapts it for spontaneous uncompensated reabsorption into a body at its own (or a lower) temperature, but not at a higher one.

The question of the determination of the form of the function ϕ in § 6 would thus appear to be closely connected with the other hitherto imperfectly fathomed problems relating to the statistics of kinetic molecular theory. A very interesting attack on the problem from this point of view has recently been made by Planck. It of course suffices to examine some simple type of radiating system, and the results will be of general validity. He considers an enclosure filled with radiation involving an entirely arbitrary succession of phases and polarizations along each ray, and also containing a system of fixed linear electric oscillators of the Hertzian type, which are taken to represent the transforming action of radiating and absorbing matter. The radiation contained in the enclosure will be passed through these oscillators over and over again, now absorbed, now radiated, and each constituent will thus settle down in a unilateral or irreversible manner towards some definite intensity and composition. But it does not appear that a system of vibrators of this kind, each with its own period, can perform one of the main functions of a material absorber, namely, the transformation of the relative intensities of the various types of radiation in the enclosure to those corresponding to a common temperature. There would be equilibrium established only between the mean internal vibratory energy in the vibrators of each period and the density of radiation of that period; there is needed also some means of interchanging energy between vibrators of different periods, which probably involves doing away with their fixity. In the absence of any method of introducing this temperature equilibrium directly, Planck sought, in the case of each independent constituent, for a function of its intensity of energy and its wave-length, restricted as to form by a certain assumed molecular relation, which has the property of continually increasing after the manner of entropy, during the progress of that constituent of the radiation in such a system towards its steady state. If the actual entropy S per unit volume were thus determined, the relation of Clausius $\delta S = \delta E/T$ would supply the connexion between the temperature and the density of radiant energy E. The procedure of Planck led him, in an indirect and tentative manner, to a relation

$d^2S/dE^2 = a/E$, so that $S = aE \log \beta E$, where a, β are functions of λ; this expression conducts through Clausius's relation to $E = \frac{1}{e\beta}e^{-1/aT}$. The previous argument then gives the formula $E(\lambda,T)\delta\lambda = c_1\lambda^{-5}e^{-c/\lambda T}d\lambda$, which was originally suggested by Wien on the basis of the analogy that it assigns the same distribution for the radiant energy, among the various frequencies of vibration, as for the energy of the molecules in a gas among their various velocities of translation.

Processes may be theoretically assigned for the direct continuous transformation of radiant into mechanical energy. Thus we can imagine a radiating body at the centre of a wheel, carrying oblique vanes along its circumference, which reflect the radiation on to a ring of parallel fixed vanes, which finally reverse its path and return it to the centre. The pressure of the radiation will drive the wheel, and in case its motion is not resisted, a very great velocity may be theoretically obtained. The thermodynamic compensation in such cases lies in the reduction of the effective temperature of the portion of the radiation not thus used up. We might even do away with the radiating body at the centre of the wheel, and consider a beam of definite radiation reflected backwards and forwards across a diameter. It is easy to see that its path will remain diametral; the work done by it in driving the wheel will be concomitant with increase of the wave-length, and therefore with expansion of the length occupied by the beam. The thermodynamic features are thus analogous to those of the more familiar case of an envelope filled with gas, which can change its thermal energy into mechanical energy by expansion of the envelope against mechanical resistances. In the case of the expanding gas $pv = \frac{2}{3}E_0$, where E_0 is the total translatory energy of the molecules, while in adiabatic expansion $p = kv^{-\gamma}$. Thus the work gained in unlimited expansion, $\int pdv$, is $\frac{2}{3}E_0/(\gamma - 1)$. The final temperature being absolute zero, this should by Carnot's principle be equal to the total initial energy of the gas that is in connexion with temperature, constitutive energy of the molecules being excluded; when $\gamma - 1$ is less than $\frac{2}{3}$ there is thus internal thermal energy in the molecules in addition to the translatory energy. In the case of the beam of radiation, of length l, between n and $n + \delta n$ reflexions, where δn is an integer, its *total* energy E is by § 2 reduced according to the law $\frac{\delta E}{E} = -\frac{4cv\delta n}{(c+v)^2}$. Also $\frac{\delta l}{l} = \frac{2v\delta n}{c+v}$; thus $\frac{\delta E}{E} = -\frac{2c}{c+v}\frac{\delta l}{l}$. When v is small compared with c, this gives $E = \kappa l^{-2}$; and p is then $2E/l$, so that $\int pdl = E$, the temperature of the beam being ultimately reduced to absolute zero by the unlimited expansion. This is in accord with Carnot's principle, in that the whole energy of the beam travelling in a vacuum is mechanically available when reduction to absolute zero of temperature is in our power.

12. *Experimental Knowledge.*—Under the stimulus of Wien's investigation, the general character of the curve connecting energy and wave-length in the complete radiation at a given temperature has been experimentally ascertained over a wide range. At each temperature there is a wave-length λ_m of maximum radiation, which travels towards the ultra-violet as the temperature rises, and Wien's law of homology (§ 6) shows that $\lambda_m T$ should be constant. This deduction, and the law of homology itself, as also the law of Stefan and Boltzmann that the total radiation varies as T^4, have been closely verified by the experiments of Lummer and Pringsheim, and of Paschen and others; they established a steady field of radiation inside a material enclosure by raising the walls to a definite temperature, and measured the radiant intensity emitted from it through an opening in the walls, by means of a bolometer or thermopile, this being the radiation of the so-called perfectly black body. It has been remarked by Planck and by Thiesen that the coefficient of T^4 in Stefan's law, and the value of $\lambda_m T$, are two absolute physical constants independent of any particular kind of matter, which in conjunction with the constant of gravitation would determine an entirely absolute system of physical units. The form of the function $\phi(T\lambda)$ adopted by Wien and Planck, namely, $c_1 e^{-c/T\lambda}$, has been found to agree fairly with experiment over the range from 100° C. to 1300° C., when $c_1 = 1\cdot24 \times 10^{-5}$ and $c = 1\cdot4435$ in c.g.s. measure, but not so well when the range is further extended: it appears that a larger value of c is needed to represent the radiation for high values of $T\lambda$, that is, for high temperature or for very long wave-lengths. Thiesen proposed the somewhat more general form $c_1(T\lambda)^k e^{-c/T\lambda}$, and suggests with good reason that the value $k = \frac{1}{2}$ agrees better with the experimental numbers than Wien's value $k = 0$. Lord Rayleigh has been led (*Phil. Mag.*, June 1900) towards this form with k equal to unity from entirely different theoretical considerations, on the assumption of the Maxwell–Boltzmann distribution of the energy of the molecule among its free periods of vibration, infinite in number; in some cases this form appeared to give as good results as Wien's, but it has been shown that it is not adapted to short wave-lengths, and that it is infected with systematic errors.

Acting on a suggestion advanced by Lord Rayleigh, Rubens and Kahlbaum have recently widely extended the test of the formulæ by means of the so-called "Reststrahlen." A substance which exhibits selective absorption of any group of rays also powerfully reflects those rays; and Rubens has been able thus to isolate in considerable purity the rays belonging to absorption bands very far down in the ultra-red, of wave-length of order 60×10^{-5} cm., in the case of substances such as sylvin, by means of five or six successive reflexions of the beam of radiation. By experiments ranging between temperatures $-200°$ C. and $+1500°$ C. it has now been found that the intensity of this definite radiation tends to vary simply as T, with close approximation, thus increasing indefinitely with the temperature, whereas Wien's formula would make it tend to a definite limit. The only existing formula (except the one suggested by Lord Rayleigh) that proved to be in accord with this result was a new one advanced shortly before on theoretical grounds by Planck, namely, $E_\lambda \delta\lambda = C\lambda^{-5}\delta\lambda/(e^{c/\lambda T} - 1)$, which for small values of λT agrees with Wien's original form, known to be there satisfactory, while for larger values it tends towards $C/c.\lambda^{-4}T$; it is, in fact, the simplest and most likely form that satisfies these two conditions. But it should be noticed that the point of Lord Rayleigh's argument was that, at any rate at low frequencies, there should be an equable partition of the energy between the temperature heat and the radiant vibrations, and that therefore the energy of the latter should ultimately vary as T; this prediction, which has thus been verified, may be grafted on either to Wien's form or to a new one after the manner of Planck. Recognizing that his previous hypothesis restricting the nature of the entropy, in addition to its property of continually increasing, had to be abandoned, as leading to results not in accord with experiment, Planck had in fact made a fresh start on the basis of a train of ideas which was introduced by Boltzmann in 1877, in order to obtain a precise physical definition of entropy. According to the latter, for an indefinitely numerous system of molecules with known properties and under given conditions there is a definite probability of the occurrence of each statistical distribution of velocities or "complexion" of the system that is formally possible, when all velocities consistent with given total energy are considered to be equally likely as regards each molecule; the distribution of greatest probability is the state of thermal equilibrium of the system, and the probability of any other state is a function of the entropy of that state. This conception can be developed only in very simple cases; the case of an ideal monatomic gas-system led Boltzmann to take the entropy proportional to the logarithm of the probability. This logarithmic law is in fact required by the principle that the entropy of a system should be the sum of the entropies of its parts. By means of *à priori* considerations of this nature, referring to the distribution

of internal vibratory energy among a system of linear electric vibrators of given period, and its equilibrium with the density of the surrounding radiant energy, Planck has been guided to an expression for the law of dependence of the entropy of that system on the temperature, which corresponds to the form of the law of radiation above stated: whatever may be thought of the cogency of his argument, especially in view of the circumstance that his vibrators cannot change the types of the radiation,[1] the result gains support from the fact that it involves determinations of the absolute physical constants of molecular theory that prove to be of the correct order of magnitude. By an argument based on the theory of dimensions, Lorentz has recently been led to the conclusion that consistency between temperatures as measured molecularly and as measured by the laws of radiation requires that the ultimate indivisible electric charges or electrons must be the same in all kinds of matter.

13. *Modification by a Magnetic Field.*—The theory of exchanges of radiation, which makes the equilibrium of radiating bodies depend on temperature alone, requires that, when an element of surface of one body is radiating to an element of surface of another body at the same temperature, the amounts of energy interchanged (when reflexion is counted in along with radiation) should be equal. This proposition is a general dynamical consequence—on the basis of the analytical method developed in this connexion mainly by Helmholtz, Kirchhoff, and Rayleigh —of the form of the equations of propagation of vibrations in the medium. But in a material medium under the influence of a strong magnetic field these equations are altered by the addition of extraneous terms involving differential coefficients of the third order, and the dynamical consistency of the cardinal principle of the theory of exchanges is no longer thus directly verified. A system of this kind has in fact been imagined by Wien in which the principle is imperfectly fulfilled. A beam coming from a body A, and polarized by passage through a nicol, may have its plane of vibration rotated through half a right angle by crossing a magnetically active plate, and may then pass through another nicol, properly orientated for transmission, so as finally to fall on another body B. On the other hand, the radiation from B which gets through this adjacent nicol will have its plane of vibration rotated through half a right angle by the magnetically active plate, and so will not get through the first nicol to the body A. Such possibilities of unequal exchange of radiation between A and B are the result of the want of reversibility of the radiation in a magnetic field, which might have been expected to lead to proportionate inequalities of concentration; in this example, however, though the defect of reversibility is itself slight, its results appear at first sight to affect the whole radiation. But a closer examination removes this discrepancy. In order to make the system self-contained, reflectors must be added to it, so as to send back into the sources the polarized constituents that are turned aside out of the direct line by the nicols. Then, as Brillouin has pointed out, and as in fact Lord Rayleigh had remarked some years before, the radiation from B does ultimately get across to A after passage backward and forward to the reflectors and between the nicols: this, it is true, increases the length of its path, and therefore diminishes the concentration of a single narrow beam, but any large change of path would make the beam too wide for the nicols, and thus require other corrections which may be supposed to compensate. The explanation of the slight difference that is to be anticipated on theoretical grounds might conceivably be that in such a case the magnetic influence, being operative on the phases, alters the statistical constitution of the radiation of given wave-length from the special type that is in equilibrium with a definite temperature, so that after passage through the magnetic medium it is not in a condition to be entirely absorbed at that temperature; there would then be some other element, in addition to temperature, involved in equilibrium in a magnetic field. If this is not so, there must be some thermodynamic compensation involving reaction, extremely small, however, on the magnetizing system.

14. *Origin of Spectra.*—In addition to the thermal radiations of material substances, those, namely, which establish temperature-equilibrium of the enclosure in which they are confined, there are the fluorescent and other radiations excited by extraneous causes, radiant or electric or chemical. Such radiations are an indication, by the presence of higher wave-lengths than belong in any sensible degree to the temperature, that the steady state has not arrived; they thus fade away, either immediately on the cessation of the exciting cause, or after an interval. The radiations, consisting of definite narrow bright lines in the spectrum, that are characteristic of the gaseous state in which each molecule can vibrate freely by itself, are usually excited by electric or chemical agency; thus there is no ground for assuming that they always constitute true temperature radiation. The absorption of these radiations by strata of the same gases at low temperatures proves that the unaltered molecules themselves possess these free periods, which do not therefore belong specially to dissociated ions. Although very difficult to excite directly, these free vibrations are then excited under the influence of resonance, which naturally becomes extremely powerful when the tuning is exact; this indicates, moreover, that the true absorption bands in a gas must be extremely narrow. There is direct evidence that many of the more permanent gases do not sensibly emit light on being subjected to high temperature alone, when chemical action is excluded, while others give under those circumstances feeble continuous spectra; in fact, the more permanent gases are very transparent to most kinds of radiation, and therefore must be very bad radiators as regards those kinds. The dark radiation of flames has been identified with that belonging to the specific radiation of their gaseous products of combustion. There is thus ground for the view that the impacts of the colliding molecules in a gas, or rather their mutual actions as they swing sharply round each other in their orbits during an encounter, may not be sufficiently violent to excite sensibly the free vibrations of the definite periods belonging to the molecules. But they may produce radiation in other ways. While the velocity of an electron or other electric charge is being altered, it necessarily sends out a stream of radiation. Now the orbital motions of the electrons in an actual molecule must be so adjusted, as appears to be theoretically possible, that it does not emit radiation when in a steady state, and therefore when it is moving with constant velocity. But in the violent changes of velocity that occur during an encounter this equipoise will be disturbed, and a stream of radiation, without definite periods, but such as might constitute the equilibrium thermal radiation of the substance, may be expected while the encounter lasts. At very high temperatures the energy of this thermal radiation in an enclosure entirely overpowers the kinetic energy of the molecules present, for the former varies as T^4, while the latter measures T itself when the number of molecules remains the same. The selective emission of gases, confined as it is to extremely narrow bands in the spectrum, may indeed be expected to possess

[1] The argument has been recast recently by Larmor, so as to avoid the introduction of vibrators.

such intensity as to be thermally in equilibrium with extremely high temperatures. That the same gases absorb such radiations when comparatively cold and dark does not of course affect the case, because emissive and absorptive powers are proportional only for incident radiations of the intensity and type corresponding to the temperature of the body. Thus if our adiabatic enclosure of § 3 is prolonged into a tube of unlimited length which is filled with the gas, then when the temperature has become uniform that gas must send back out of the tube as much radiation as has passed down the tube and been absorbed by it; but if the tube is maintained at a lower temperature, it may return much less. The fact that it is now possible by great optical dispersion to make the line-spectra of prominences in the middle of the Sun's disc stand out bright against the background of the continuous solar spectrum, shows that the intensities of the radiations of these prominences correspond to a much higher temperature than that of the general radiating layer underneath them; their luminosity would thus seem to be due to some cause (electric or chemical) other than mere temperature. On the other hand, the general reversing gaseous layer which originates the dark Fraunhofer lines is at a lower temperature than the radiating layer, and is probably in the same relatively steady thermal state as its surroundings. When the radiation in a spectrum is constituted of broad bands it may on these principles be expected to be in equilibrium with a lower temperature than when it is constituted of narrow lines, if the total intensity is the same in the cases compared; this is in keeping with the easier excitation of band spectra (cf. the banded absorption spectra), and with the fact that various gases and vapours do appear to emit band spectra in equilibrium with the temperature.

15. *Constitution of Spectra.*—In the problem of the unravelling of the constitutions of the very complex systems of spectral lines belonging to the various kinds of matter considerable progress has been made in recent years. The beginning of definite knowledge was the discovery of Balmer in 1885, that the frequencies of vibration (n) of the hydrogen lines could be represented, very closely and within the limits of error of observation, by the formula $n \propto 1 - 4m^{-2}$, when for m is substituted the series of natural numbers 3, 4, 5, $\cdots\cdot$ 15. Soon afterwards series of related lines were picked out from the spectra of other elements by Liveing and Dewar. Rydberg conducted a systematic investigation on the basis of a modification of Balmer's law for hydrogen, namely, $n = n_0 - \mathrm{N}/(m+\mu)^2$. He found that in the group of alkaline metals three series of lines exist, the so-called principal and two subordinate series, whose frequencies fit approximately into this formula, and that similar statements apply to other natural groups of elements; that the constant N is sensibly the same for all series and all substances, while n_0 and μ have different values for each; and that other approximate numerical relations exist. In each series the lines of high frequency crowd together towards a definite limit on the more refrangible side; near this limit they would, if visible, constitute a band. In most series there are, however, not more than six lines visible: helium and hydrogen are exceptions, no less than thirty lines of the principal series of the latter having been identified, the higher ones in stellar spectra only. The principal or strongest series of lines shows reversal very readily. The lines of the first subordinate series are usually nebular, while those of the second subordinate or weakest series are sharp, but with a tendency to broaden towards the less refrangible side. Simultaneously with Rydberg, the problem was attacked by Kayser and Runge, who used the formula $n = \mathrm{A} + \mathrm{B}m^{-2} + \mathrm{C}m^{-4}$, higher terms in this descending series being presumed to be negligible. This cannot be reconciled with Rydberg's form, which gives on expansion terms involving m^{-3}; but for the higher values of m the discrepancies rapidly diminish, and do not prevent the picking out of the lines, the frequency-differences between successive lines then varying roughly as the inverse squares of the series of natural numbers. For low values of m neither mode of expression is applicable, as was to be expected; and it remains a problem for the future to ascertain if possible the rational formula to which they are approximations. Considered dynamically, the question is that of the determination of the formula for the free simple harmonic periods of the vibrating system which constitutes the molecule. Although we are still far from any definite line of attack, there are various indications that the quest is a practicable one. The lines of each series, sorted out by aid of the formulæ above given, have properties in common: they are usually multiple lines, either all doublets in the case of monad elements, or generally triplets in the case of those of higher chemical valency; in very few cases are the series constituted of single lines. It is found also that the components of all the double or triple lines of a subordinate series are equidistant as regards frequency. In the case of a related group of elements, for example the alkaline metals, it appears that corresponding series are displaced continually towards the less refrangible end as the atomic weight rises; it is found also that the interval in frequency between the double lines of a series diminishes with the atomic weight, and is proportional to its square. These relations suggest that the atomic weight might here act in part after the manner of a load attached to a fundamental vibrating system, which might conceivably be formed on the same plan for all the metals of the group; such a load would depress all the periods, and at the same time it would split them up in the manner above described, if it introduced dissymmetry into the vibrator. The discovery of Zeeman that a magnetic field triples each spectral line, and produces definite polarizations of the three components, in many cases further subdividing each component, is explained, and was in part predicted, by Lorentz on the basis of the electron theory which finds the origin of radiation in a system of unitary electric charges describing orbits or executing vibrations in the molecule. Although these facts form substantial sign-posts, it has not yet been found possible to assign any likely structure to a vibrating system which would lead to a frequency formula for its free periods of the types given above. Indeed, the view is open that the group of lines constituting a series form a harmonic analysis of a single fundamental vibration not itself harmonic. If that be so, the intensities and other properties of the lines of a series ought all to vary together; it has in fact been found by Preston that the lines are multiplied into the same number of constituents in a magnetic field, with intervals in frequency that are the same for all of them. When the series consists of double or triple lines the separate components of the same compound line are not affected similarly, which shows that they are differently constituted. The view has also found support that the different behaviours of the various groups of lines in a spectrum show that they belong to independent vibrators.

According to Rydberg, there is ground for the view that a natural group of chemical elements have all the same type of series spectrum, and that the various constants associated with this spectrum change rapidly in the same directions in passing from the elements of one group to the corresponding ones of the following groups, after the manner illustrated in graphical representations of Mendeléeff's law by means of a continuous wavy curve in

which each group of elements lies along this same ascending or descending branch; the chemical elements thus being built up in a series of types or groups, so that the individuals in successive groups correspond one to one in a regular progression, which may be put in evidence by connecting them by transverse curves.

The frequencies of the series of very close lines which constitute a single band in a banded spectrum are connected by a law of quite different type, namely, in the simpler cases $n^2 = \mathrm{A} - \mathrm{B}m^2$. It may be remarked that this is the kind of relation that would apply to a row of independent similar vibrators in which the neighbours exert slight mutual influence of elastic type. If ξ denote displacement and x distance along the row, the equation $\frac{d^2\xi}{dt^2} + k^2\xi = -g\frac{d^2\xi}{dx^2}$ would represent the general features of their vibration, the right-hand side arising from the mutual elastic influences. If the ends of the line of vibrators, of length l, are fixed, or if the vibrators form a ring, the appropriate type of solution is $\xi \propto \sin \mu x \sin pt$, where $\mu l = m\pi$ and m is integral; further $-p^2 + k^2 = g\mu^2$, hence $p^2 = k^2 - \frac{g\pi^2}{l^2}m^2$, which is of the type above stated. Dynamical systems of this kind are illustrated by the Lagrangean linear system of connected bodies, such as, for example, a row of masses fixed along a tense cord, and each subject to a restoring elastic force of its own in addition to the tension of the cord. A single spectral line might thus be transformed into a band of this type as the effect of disturbance arising from slight elastic connexions established in the molecule between a system of similar vibrators. But the series in line-spectra are of entirely different constitution; thus for the series expressed by the formula $p^2 = p_o^2 - \mathrm{B}m^{-2}$ the corresponding period-equation may be expressed in the form $\sin k(p^2 - p_o^2)^{-\frac{1}{2}} = \text{constant}$, which belongs to no type of vibrator hitherto analysed.

The original memoirs by the writers above mentioned are mostly in Wiedemann's *Annalen der Physik*; references are given by P. Drude, *Lehrbuch der Optik*, Leipzig, 1900. There are important reports by the same writers in the collection issued by the International Congress of Physics, Paris, 1900. See also Lord Rayleigh's *Scientific Papers*; and Larmor, in *Brit. Assoc. Reports*, 1900, 1902. In spectrum analysis Kayser's elaborate treatise is the standard authority. Winckelmann's *Handbuch der Physik*, vol. ii. (by Kayser, Drude, &c.), may also be consulted. (J. L*.)

Radiometer.—It has been remarked at various times, amongst others by Fresnel, that bodies delicately suspended within a partial vacuum are subject to apparent repulsion by radiation. The question was definitely investigated by Sir W. Crookes, who had found that some delicate weighings *in vacuò* were vitiated by this cause. It appeared that a surface blackened so as to absorb the radiant energy directed on it was repelled relatively to a polished surface. He constructed an apparatus in illustration, which he called a *radiometer* or *light-mill*, by pivoting a vertical axle carrying equidistant vertical vanes inside an exhausted glass bulb, one side of each vane being blackened and the other side bright, the blackened sides all pointing the same way round the axle. When the rays of the sun or a candle, or dark radiation from a warm body, are incident on the vanes, the dark side of each vane is repelled more than the bright side, and thus the vanes are set into rotation with accelerated speed, which becomes uniform when the forces produced by the radiation are balanced by the friction of the pivot and of the residual air in the globe. The name radiometer arose from an idea that the final steady speed of rotation might be utilized as a rough measure of the intensity of the exciting radiation.

The problem of the cause of these striking and novel phenomena at first produced considerable perplexity. A preliminary question was whether the mechanical impulsion was a direct effect of the light, or whether the radiation only set up internal stresses, acting in and through the residual air, between the vanes and the walls of the enclosure. The answer to this was found experimentally by Schuster, who suspended the whole instrument in delicate equilibrium, and observed the effect of turning on the radiation. If the light exerted direct impulsion on the vanes, their motion would gradually drag the case round after them, by reason of the friction of the residual air in the bulb and of the pivot. On the other hand, if the effects arose from balanced stresses set up inside the globe by the radiation, the effects on the vanes and on the case would be of the nature of action and reaction, so that the establishment of motion of the vanes in one direction would involve impulsion of the case in the opposite direction; but when the motion became steady there would no longer be any torque either on the vanes or on the case, and the latter would therefore come back to its previous position of equilibrium; finally, when the light was turned off, the decay of the motion of the vanes would involve impulsion of the case in the direction of their motion until the moment of the restoring torque arising from the suspension of the case had absorbed the angular momentum in the system. Experiment showed that this was what happened. The important part played by the residual air in the globe had also been deduced by Osborne Reynolds from observing that on turning off the light, the vanes came to rest very much sooner than the friction of the pivot alone would account for; in fact, the rapid subsidence is an illustration of Maxwell's great theoretical discovery that viscosity in a gas (as also diffusion both of heat and of the gas itself) is sensibly independent of the density.

The origin of these phenomena was recognized, among the first by O. Reynolds, and by Tait and Dewar, as a consequence of the kinetic theory of the constitution of gaseous media. The temperature of a gas is measured by the mean energy of translation of its molecules, which are independent of each other except during the brief intervals of collision; and collision of the separate molecules with the blackened surface of a vane, warmed by the radiation, imparts heat to them, so that they rebound from it with greater velocity than they approached. This increase of velocity implies an increase of the reaction on the surface, the black side of a vane being thus pressed with greater force than the bright side. In air of considerable density the mean free path of a molecule, between its collisions with other molecules, is exceedingly small, and any such increase of gaseous pressure in front of the black surface would be immediately neutralized by flow of the gas from places of high to places of low pressure. But at high exhaustions the free path becomes comparable with the dimensions of the glass bulb, and this equalization is only partial. The general nature of the phenomena is thus easily understood; but the problem of the stresses in gaseous media arising from inequalities of temperature, which is thereby opened out, involves some of the most delicate considerations in molecular physics. It remains practically as it was left in 1879 by two memoirs communicated to the *Philosophical Transactions* by Osborne Reynolds and by Clerk Maxwell. The method of the latter investigator was purely *à priori*. He assumed that the distribution of molecules and of their velocities, at each point, was slightly modified, from the exponential law belonging to a uniform condition, by the gradient of temperature in the gas (see Diffusion of Gases). The hypothesis that the state was steady, so that interchanges arising from convection and collisions of the molecules produced no aggregate result, enabled him to interpret the new constants involved in this law of distribution, in terms of the

temperature and its spacial differential coefficients, and thence to express the components of the stress at each point in the medium in terms of these quantities. As far as the order to which he carried the approximations, the result was that the equations of motion of the gas, considered as subject to viscous and thermal stresses, could be satisfied by a state of equilibrium under a modified internal pressure equal in all directions. If, therefore, the walls of the enclosure held the gas that is directly in contact with them, this equilibrium would be the actual state of affairs; and it would follow from the principle of Archimedes that, when extraneous forces such as gravity are not considered, the gas would exert no resultant force on any body immersed in it. On this ground Maxwell inferred that the forces acting in the radiometer are connected with gliding of the gas along the unequally heated boundaries; and as the laws of this slipping, as well as the constitution of the adjacent layer, are uncertain, the problem becomes very intricate. Reynolds, introducing no new form of law of distribution of velocities, uses a linear quantity, proportional to the mean free path of the gaseous molecules, which he takes to represent (somewhat roughly) the average distance from which molecules directly affect, by their convection, the state of the medium; the gas not being uniform on account of the gradient of temperature, the change going on at each point is calculated from the elements contributed by the parts at this particular distance in all directions. He lays stress on the dimensional relations of the problem, pointing out that the phenomena which occur with large vanes in highly rarefied gas could also occur with proportionally smaller vanes in gas at higher pressure. The results coincide with Maxwell's so far as above stated, though the numerical coefficients do not agree. According to Maxwell, priority in showing the necessity for slipping over the boundary rests with Reynolds, who also discovered the cognate fact of thermal transpiration, meaning thereby that gas travels up the gradient of temperature in a capillary tube, owing to surface-actions, until it establishes such a gradient of pressure (extremely minute) as will prevent further flow. In later memoirs Reynolds followed up this subject by proceeding to establish definitions of the velocity and the momentum and the energy at an element of volume of the molecular medium, with the precision necessary in order that the dynamical equations of the medium in bulk, based in the usual manner on these quantities alone, without directly considering thermal stresses, shall be strictly valid, —a discussion in which the relation of ordinary mechanics to a complete molecular theory is involved. (J. L*.)

Radnor, an inland county of South Wales, bounded on the N. by Montgomery, on the N.E. by Shropshire, on the E. by Hereford, on the S. and S.W. by Brecknock, and on the W. by Cardigan.

Area and Population.—The area of the ancient and administrative county is 301,164 acres, or 471 square miles, with a population in 1881 of 23,528, in 1891 of 21,791, and in 1901 of 23,263, the number of persons per square mile being 49, and of acres to a person 12·8. The area of the registration county is 238,715 acres, with a population in 1891 of 17,119. Between 1881 and 1891 the population decreased at the rate of 7·58 per cent., but between 1891 and 1901 there was a recovery, although the total at the latter date was still a fraction less than in 1881. The following table gives the numbers of marriages, births, and deaths, with the number and percentage of illegitimate births, for 1880, 1890, and 1898:—

Year.	Marriages.	Births.	Deaths.	Illegitimate Births.	
				No.	Per cent.
1880	130	554	319	74	13·3
1890	103	452	299	58	12·6
1898	173	591	309	35	6·0

The percentage of illegitimacy has greatly diminished. In 1891 there were in the county 52 natives of Scotland, 32 natives of Ireland, and 22 foreigners, while 15,270 persons could speak English, 75 Welsh only, and 924 English and Welsh.

Constitution and Government.—The county returns one member to Parliament. It has neither a parliamentary nor a municipal borough, but the ancient town of Radnor (405) is governed by the provisions of an old charter. The urban districts are Knighton (2139), Llandrindod Wells (1827), and Presteigne (1237). Radnor is in the South Wales and Chester circuit, and assizes are held at Presteigne. The ancient county, which is partly in the diocese of Hereford and partly in that of St Davids, contains 41 entire ecclesiastical parishes and districts and parts of 5 others.

Education.—The total number of elementary schools in the county on 31st August 1899 was 51, of which 10 were board and 41 voluntary schools, the latter including 36 National Church of England schools, and 5 "British and other." The average attendance at board schools was 439, and at voluntary schools 2483. The total school board receipts for the year ended 29th March 1899 were over £1663. The income under the Agricultural Rates Act was over £325.

Agriculture and Industry.—More than half the total area of the county is under cultivation, but of this nearly three-fourths is in permanent pasture, in addition to which about 117,000 acres of hill pasturage are grazed, chiefly by sheep, which are largely kept. About 700 acres are under orchards, and about 11,000 acres under woods. Oats are the principal corn crop, occupying more than three-fifths of that area, while wheat and barley, each having about the same acreage, occupy together less than two-fifths. Turnips occupy five-sixths of the area under green crops, the acreage under potatoes being insignificant. The following table gives the larger main divisions of the cultivated area at intervals from 1880:—

Year.	Total Area under Cultivation.	Corn Crops.	Green Crops.	Clover.	Permanent Pasture.	Fallow.
1880	155,895	23,070	7334	15,961	107,370	2160
1885	157,483	21,129	7129	14,055	113,652	1518
1890	163,442	20,407	7305	13,933	120,433	1359
1895	162,550	18,858	7035	14,270	121,619	764
1900	163,240	18,937	6752	16,173	120,718	654

The following table gives particulars regarding the principal live stock for the same years:—

Year.	Total Horses.	Total Cattle.	Cows or Heifers in Milk or in Calf.	Sheep.	Pigs.
1880	8,879	29,855	9,482	245,559	5131
1885	9,398	32,297	10,706	257,965	6371
1890	9,604	31,493	10,712	272,325	6530
1895	10,266	32,633	10,266	270,761	5692
1900	9,677	34,538	11,048	283,590	4909

In 1898, 65,814 tons of sandstone were raised, 35,372 tons of limestone, and 36,560 tons of igneous rocks.

AUTHORITIES.—INCE. *Views Illustrating the County of Radnor.* London, 1832.—WILLIAMS. *The History of Radnorshire* (reprinted from the *Archæologia Cambrensis*). Tenby, 1858.—Guide-books to South Wales.

Radom, a southern frontier government of Russian Poland, bordering on Galicia. It has an area of 4765 square miles, and a population which numbered 820,363 in 1897, when there were 409,624 women, and the urban population numbered 94,318. Poles formed 80 per cent. of the population, and Jews 17 per cent. The province is divided into 7 districts, the chief towns of which are Radom (see below), Iłża (4168), Konsk (8235), Kozenice (5327), Opatów (6942), Opoczno (6022), and Sędomierz (6534). In 1899 there were 4 gymnasia for boys and girls and 154 primary schools—altogether, 440 schools, including the Jewish *hedars*, with about 20,000 pupils. The soil is mostly fertile, and agriculture, the main occupation of the people, is in good condition; out of 2,461,700 acres of land in 1896, 1,383,600 were under cultivation and 874,000 under woods. The crops in 1900 were: wheat, 805,000 cwt.; rye, 2,548,000 cwt.; barley, 896,000 cwt.; oats, 1,540,000 cwt.; and potatoes, 11,724,000 cwt., chiefly cultivated for distilleries. Grain is exported. Live stock is kept in large numbers, there being, in 1897, 116,000 horses, 241,000 horned cattle, 175,000 sheep, and 120,000 swine. Manufactures have

considerably developed of late years, the province being rich in iron ore. The iron industry occupies more than 60,000 workmen, and in 1898, 2,013,873 cwt. of pig iron, 501,117 cwt. of iron, and 1,058,296 cwt. of steel were produced. There are also several sugar works. The total return from all industries in 1898 was 19,899,000 roubles.

Radom, the capital of the above province, situated 65 miles south of Warsaw, on the railway from Minsk to Vienna. It has several iron and agricultural machinery works and tanneries. Population (1897), 28,749.

Radomysl (formerly MYCHEK), a district town of Russia, in the government and 64 miles north-west of the town of Kieff, on the Tetereff river. It is a very old town, and was mentioned in the annals in 1150; in the 18th century it was the residence of the metropolitans of the United Church. It has several tanneries and flour mills, and exports timber, corn, and mushrooms. Population (1897), 18,154.

Rae Bareli, a town and district of British India, in the Lucknow division of Oudh. The town is on the river Sai, 48 miles south-east of Lucknow, and has a railway station. Population (1881), 11,781; (1891), 18,798; municipal income (1897–98), Rs.27,133, two-thirds derived from octroi; registered death-rate (1897), 75·65 per thousand. The DISTRICT of Rae Bareli has an area of 1751 square miles. Population (1881), 951,905; (1891), 1,036,521, showing an increase of 9 per cent., compared with a decrease of 4 per cent. in the preceding twelve years; average density, 592 persons per square mile. In 1901 the population was 1,033,948, showing a slight decrease. The land revenue and rates are Rs.15,58,430, the incidence of assessment being R.1.5.7 per acre; cultivated area (1896–97), 459,608 acres, of which 285,998 were irrigated from wells, &c.; number of police, 2850; vernacular schools, 136, with 5724 pupils; registered death-rate (1897), 50 per thousand. The principal crops are rice, pulse, wheat, barley, millet, and opium. Rae Bareli town is connected with Lucknow by a branch of the Oudh and Rohilkhand Railway, which in 1898 was extended to Benares. There are no Government canals.

Ragatz, a watering-place in the Swiss canton of St Gall, 12½ miles by rail north of Coire. In 1900 the population was 1861. From Ragatz a funicular railway runs up in ten minutes to the Wartenstein Hotel, above the ruins of the 14th-century ruined castle of that name. A short distance beyond the hotel are the buildings of the ancient abbey of Pfäffers, now turned into a lunatic asylum and hospital. Pfäffers is 2697 feet above the sea.

Ragusa, a city of the province of Syracuse, Sicily, Italy. It embraces two separate communes, RAGUSA SUPERIORE, 76 miles west by south of Syracuse on the railway to Licata, and RAGUSA INFERIORE, 3 miles by rail farther to the east. There are several old churches and rock caves, and various industries, such as asphalt and limestone quarries, cotton, macaroni, and cheese factories. Population of Ragusa Superiore (1881), 24,236; (1899), about 23,000; of Ragusa Inferiore (1889), 6260; (1899), about 8000.

Ragusa, a city on the east coast of the Adriatic, in the Austrian province of Dalmatia. Population (1890) of city, 7143, and of commune, 11,177; in 1900, 13,174, including a garrison of 1122 men. Of these, it is estimated that 93 per cent. are Serbo-Croatians, 4 per cent. Italians, and 3 per cent. Germans; and that 92 per cent. are Catholic, 5 per cent. Protestant, and 3 per cent. Jewish. The industries include the manufacture of oil, silks, leather, and liqueurs. There is some transit trade with Herzegovina. The city is now connected with its hinterland by an extension of the Bosnian railway system to Gravosa, the harbour of Ragusa.

Ragusavecchia, a market-place in the government district of Ragusa, in Dalmatia, about 6 miles south-east of the latter city. It occupies the site of the ancient Epidaurum, destroyed by the Slavs in the 7th century, and contains the ruins of a bath and aqueduct of the Roman period. Population (1890) of village, 723, and of commune, 9949; (1900) 10,690, Serbo-Croatians.

Rahway, a city of Union county, New Jersey, U.S.A. It is situated in 40° 37′ N. and 74° 17′ W., on the Rahway river and on the Pennsylvania Railroad, in the north-eastern part of the state. Its site is level, and the street plan regular. To some extent it serves as a residential suburb of New York, which is distant but 19 miles. It has carriage factories, publishing houses, woollen mills, and other manufactures. Population (1895), 7915; (1900), 7935, of whom 1345 were foreign-born and 349 negroes.

Raid.—A raid, in the language of international law, is an invasion by armed forces, unauthorized and unrecognized by any State, of the territory of a State which is at peace. Piracy is the attack on the high sea of any vessel by an armed vessel, not authorized or recognized by any State, for the purpose of robbery. A raid for the purpose of carrying off movable property and converting it to the use of the captors would still be distinguishable from piracy, because it was committed on territory subject to an exclusive territorial jurisdiction. Where the attack or invasion by an armed ship not authorized or recognized by any State is not for the purpose of capturing property, it is properly speaking a raid and not piracy. An attack though in time of peace, by armed forces authorized or recognized by a regular Government is not a raid but an act of war, there being a Government responsible for the act committed. The fact of any act being authorized, not by the supreme Government, but by a chartered company, or by its governing officer, makes no difference in international law, the directorate of a chartered company exercising its powers by delegation of the State under which it holds its charter. The acts of its armed forces cannot in reason be distinguished from the acts of the armed forces of the State Government. Thus compensation is just as much due for them as for the deliberate acts of the State itself, and any claim of an injured State can only be preferred against the State to which the company belongs. Invasion by the regular forces of a State, or by the regular forces of its delegated authority, being an act of war, the laws of war apply to it, and, on capture, such forces, or any members or part of such forces, are prisoners of war. On the other hand, the State whose subordinate authorities commit acts of war against a friendly State has the option of following them up as a commencement of hostilities, or of giving satisfactory compensation to the invaded State. Where the invasion is not by forces subject to the orders of a State, the invaded State has the right to apply its own laws for the repression of disturbances in its territory. Thus, in the so-called Jameson Raid, the Transvaal Government had no right to treat Dr Jameson, an officer holding his powers under the British Government, and his subordinates, as outlaws, and it was probably so advised, and the British Government owed proper compensation for an act for the consequences of which, under international law, it was responsible.

British domestic law punishes raiding under the Foreign Enlistment Act, 1870 (33 & 34 Vict. c. 90). Section 11 of this Act provides as follows:—"If any person within the limits of His Majesty's dominions, and without the licence of His Majesty, prepares or fits out any naval or military

expedition to proceed against the dominions of any friendly State, the following consequences shall ensue: (1) Every person engaged in such preparation or fitting out, or assisting therein, or employed in any capacity in such expedition, shall be guilty of an offence against this Act, and shall be punishable by fine and imprisonment or either of such punishments, at the discretion of the Court before which the offender is convicted; and imprisonment, if awarded, may be either with or without hard labour. (2) All ships and their equipments, and all arms and munitions of war, used in or forming part of such expedition, shall be forfeited to His Majesty." Section 12 provides for the punishment of accessories as principal offenders, and section 13 limits the term of imprisonment for any offence under the Act to two years. In the Sandoval case (1886), in which Colonel Sandoval, who was not a British subject, bought guns and ammunition and shipped them to Antwerp, where they were put on board a vessel, which afterwards made an attack on Venezuela, it was held that the offence of fitting out and preparing an expedition within British territory against a friendly State, under this section, is sufficiently constituted by the purchase of guns and ammunition in the British Empire, and their shipment for the purpose of being put on board a ship in a foreign port, with knowledge of the purchaser and shipper that they are to be used in a hostile demonstration against such State, though the shipper takes no part in any overt act of war, and the ship is not fully equipped for the expedition within any British port. Under the same section, Dr Jameson, administrator of the British South Africa Company, and his confederates were tried before the Central Criminal Court and sentenced to different terms of imprisonment. The offence committed under a British Act is, of course, that of preparing and fitting out an expedition on British territory. Any acts subsequently committed by any British expedition on foreign soil are beyond the operation of domestic legislation, and fall to be dealt with by the domestic legislation of the State within which they occur, or by diplomacy, as the case may be. (T. BA.)

Raigarh, a feudatory state of India, in the Chhattisgarh division of the Central Provinces. Area, 1486 square miles. Population (1891), 168,525; (1901), 174,911, showing an increase of 4 per cent., compared with an increase of 31 per cent. in the previous decade. Estimated revenue, Rs.1,27,870; tribute, Rs.4000. The chief belongs to the old Gond royal family. The state is traversed by the Bengal-Nagpur Railway, with a station at Raigarh town, 338 miles east of Nagpur. Iron ore is said to abound.

RAILWAYS.

STATISTICS.

FOR the early history of railways, a sketch of their development, statistics of the earlier stages of that development, and a picture of the state of the art of carriage by rail as it was in 1883 to 1885, the reader may consult the *Encyclopædia Britannica*, vol. xx. The present article will deal with railways as they were in the year 1900, showing something of their place in modern society, of their relations to each other and to the citizen, of the work they do, and of the present development in building, equipping, and working them. Part of this subject, however, will be covered by articles that are placed alphabetically in other volumes. Thus train brakes are treated in the article BRAKES.

At the end of 1885 there were in the world 302,887 miles of railway; by the end of 1898 the length was 466,524 miles. (In reading and using these figures, and some other general figures which will appear in this article, the fact must be recognized that it is impossible that they should be strictly accurate. They must be in error by some scores or even hundreds; but they are accurate enough for most purposes.) The increase in thirteen years was 54 per cent.; and absolutely it was more than all the railways built in the world from the beginning, in 1828, up to 1872. The increase in the United Kingdom was at less than one-fourth the average rate of the world, namely, 12¾ per cent., for the very good reason that the territory had been well occupied early in the history of railway building. By Table I. it will be seen that, relatively to area, the United Kingdom has more miles of railway than any other country except Belgium. The rate of increase in the United States was considerably below the average, namely, 44½ per cent., that country having also been very enterprising in the early years, and having more railways relatively to population than any other great nation. But the length of railway there had become so great by 1885 that an addition of 44½ per cent. made 35 per cent. of all the increase in the world in the thirteen years. In all Europe the increase was 38 per cent., while in European Russia it was 60 per cent., but that was from a small mileage. The greatest relative growths were: Australia, 80 per cent.; British India, 83½ per cent.; Japan, 750 per cent.; and all Asia, 141 per cent. But in all these cases the mileage in 1885 was but small: in Japan it was only 348 miles. By Table I. it will be seen that in those countries now fairly well supplied with railways the rate of increase is still falling, as one would expect; and the decline in the United States is a fact of tremendous importance to the whole world. For years railway building was one of the chief industries of that country, and absorbed a great part of all the capital available for investment. Probably the railways built in the United States in the four years ending 1883 cost at least $1,000,000,000 more than those built in the four years ending 1898. The release of this vast capital for other uses must affect profoundly the industries and commerce of the civilized world. The student of statistics of railways may consult the yearly census of railways of the world which appears in the May–June issue of the *Archiv für Eisenbahnwesen*, a periodical publication of the Prussian Ministry of Public Works. That census is brought up to two years before the year of its publication, and now covers many years. This publication also gives regularly, throughout each year, special studies of the railways of every nation, which are of great value.

It has been said that nothing is so cheap as the carriage of goods. It is not worth while to try to prove this—perhaps it is not absolutely true; but it is quite true that the transportation of goods is very cheap. The most instructive examples of the charges for carriage by rail may be found in the United States, for several reasons. The length of railway there is 11 per cent. more than the railways of all Europe, including the United Kingdom. The tons of freight carried are 112 per cent. more than in the United Kingdom, and the average haul is much longer than in any other great country. Furthermore, the statistics of the railways of Great Britain do not give the traffic units, tons-one-mile and passengers-one-mile,[1] so that it

[1] The North-Eastern Railway has decided to compile and publish these particulars, which it is believed have been prepared by the London and North-Western for the use of its own officials for some

is impossible to get the average cost of service there. We find, then, in the United States examples of transportation on a great scale, covering a variety of conditions; and because the United States is the most important food-producing country, it is perhaps true that the cost of transportation in the United States more closely affects the rest of the world than the cost of carriage in any other country.

In the United States in 1899 the average charge for carrying one ton one mile was 0·724 cent. In 1888 the charge was 1·001 cent. This difference of twenty-eight hundredths of a cent on each ton carried one mile made a prodigious sum in the aggregate. If the freight rates in 1899 had been as high as they were in 1888, shippers and consumers would have paid to the railways of the United States $342,000,000 more than they did pay in fact. We cannot get the average for all of the lines for any year much further back, but the figures of two representative systems of railway, one in the East and one in the West, will illustrate the fall in freight rates for the whole country. In 1870 the Pennsylvania Railroad received 1·55 cents for one ton one mile, and in 1899, 0·469 cent. In 1870 the Chicago and North-Western received 3·09 cents, and in 1899, 0·878 cent. The rates of 1870 corrected for the premium on gold would have been about 1·35 and 2·69 cents respectively in the money of 1899. This apparent decrease of about two-thirds is partly due to the greater relative growth of low-class traffic, but still it is a rough measure of the benefit which the people of the United States have enjoyed from the fall in freight rates, —a benefit which has been shared by all the world, more particularly because the United States is the great food-producing country.

We may better understand the social meaning of very cheap freight rates if we consider a few commodities of prime necessity to mankind. In 1899 a barrel of flour was carried by rail from the mills at Minneapolis to the warehouse in New York for about 52 cents on the average. The distance is 1332 miles by one of the shortest rail routes. This means that the transportation charge on an ordinary loaf of bread for 1332 miles of carriage is about one-third of a cent. The charge for carrying a barrel of flour from Minneapolis to Liverpool was about 70 cents in 1899. Rates and wages vary somewhat year by year, but in general terms we may say that the supply of bread and meat for one man one year is carried from Chicago to Liverpool for a mechanic's wages for one day. In 1899 the charge for one ton of bituminous coal from the mines of West Virginia to deep water at Newport News was $1·00 for a haul of 400 miles. Anthracite coal was carried from the mines in Pennsylvania to tide-water, 200 miles, for $1·00 a ton. In the same year a quart of milk was carried into New York from gathering grounds 260 miles away for $\frac{8}{10}$ths of a cent. Such examples might be multiplied indefinitely, and might be found in different degrees in all countries which have railways. For railways have immeasurably enlarged the market in which a man may sell his products, and they have equally broadened the field from which he may draw his sustenance. They have made modern society possible. All this is true, to a less degree, of the cost of passenger movement. That has fallen, but not so fast or so far as the charges for goods, nor are low passenger rates so necessary to society as low goods rates. Low passenger rates are important within what may be called suburban zones, that is, in the areas in which people may live and go daily to and from a city.

time. Among English railway managers, however, there is a widespread opinion that, in the conditions which exist in the United Kingdom, such particulars are not of great practical value, or at least are not essential for the proper conduct of a railway's traffic.—Ed. *E.B.*

In ideal conditions the homes of the people, and especially of the poor, must be in the country. Air, light, low rent, ground to till, and wholesome recreation for children can only be had by scattering the working population of a city into the surrounding country to sleep; and the lower the passenger rates and the faster and more frequent the trains, the broader is the zone over which the population of any given city may be scattered. In the United States from $\frac{1}{2}$ to $\frac{8}{10}$ cent a mile are the common suburban rates, good for all trains and all hours. In England the ordinary rate for working men's suburban tickets is probably not far from $\frac{1}{2}$ cent a mile. The use of these tickets is, however, restricted to certain trains and hours. Season ticket rates in England work out considerably higher than suburban rates in the United States.

Enough has been said to suggest the place of railways in civilization: the relative supply and use of railways are one measure of the relative civilization of two countries. In order to indicate the basis for such a comparison, certain statistics are collected in the following tables. The figures, however, change from year to year, and those who wish to make comparative studies should look for information in the annual statistical publications of the various countries. The tables are intended to suggest methods, rather than to serve as material for actual study.

Table I. shows miles of railway, absolute and relative, for several countries for the year 1898. It is obvious that such figures must be subject to some correction, for the reasons (among others) that statistical years and calendar years do not always coincide, and that censuses are not made every year. The table is, however, accurate enough for practical purposes. The countries in this table have been selected (1) to show the relative situation in the great nations, and (2) to compare some of the most important of the British possessions. This table also shows the rate of increase in the various countries from 1894 to 1898. It is not safe to try to reason from this increase in the past to the increase in the future, as accidental conditions may have affected the growth abnormally in any one of these countries: in the United States, for instance, the rate of increase in these four years was perhaps abnormally small, owing to the great business depression which followed the panic of 1893.

TABLE I.—*Miles of Railway in Several Countries at the end of* 1898.

Country.	Miles of Railway.	Per Cent. of Increase, 1894 to 1898.	Miles of Railway per 100 Square Miles.	Population per Mile of Railway.
United Kingdom	21,659	3·0	17·83	1,856
United States (not including Alaska)	186,396	3·9	6·26	399
Germany	30,771	9·0	14·74	1,699
Belgium	3,781	9·8	33·20	1,764
France	25,898	4·3	12·68	1,488
Russia in Europe (including Finland)	26,414	19·6	1·26	4,020
Austria-Hungary	21,805	16·9	8·33	2,059
British North America	16,870	7·0	0·51	308
British India	21,475	17·1	1·35	14,340
New South Wales	2,691	3·0	0·86	490

Table II. compares the work done by the railways of a few of the great nations; from this the United Kingdom must be omitted, since the figures of passenger-miles and ton-miles are not obtainable. Table II. gives results for 1898 in the United States and Germany, and for 1897 in the other countries. Further, the miles of line doing the work in the United States and Germany are not exactly the same as the miles in Table I., for

complete traffic returns were not gathered from all of the railways. The returns of Belgium are from the State railways only, or about seventy per cent. of the whole Belgian mileage. The columns of passenger-miles and ton-miles in Table II. show millions, six ciphers being omitted. These columns give a notion of the prodigious amount of work done by the railways, but the column of daily movement each way (3 and 4) shows the relative density of the work. These give the passengers and the tons that must be moved each way, every day, over the whole mileage in each country, to make up the totals in columns 1 and 2. Here we discover that the density of passenger traffic is least in the United States and greatest in Belgium, which is precisely what one would expect from the relative density of population of the various countries. Columns 5 and 6 show the work done relatively to the population.

TABLE II.—*Work done by the Railways of Several Countries—Absolute and Relative.* (*United States and Germany*, 1898; *other countries*, 1897.)

	Million Passenger-Miles (000,000 omitted). (1)	Million Ton-Miles (000,000 omitted.) (2)	Moved each Way every Day over the whole Mileage. Passengers. (3)	Tons. (4)	Yearly Movement per Inhabitant. Passenger-Miles (5)	Ton-Miles. (6)
United States	13,380	101,855	99	748	180	1,376
Germany	10,934	17,958	500	820	209	343
France	7,228	8,482	386	454	188	221
Austria	2,506	5,830	318	740	98	228
Hungary	1,320	2,423	181	332	70	129
Belgium	1,240	1,711	849	1,170	190	262

Table III. gives the rolling stock of a few countries, showing not only the absolute number of locomotives and cars, but the number for each 100 miles of railway. It is not seriously misleading to compare the equipment per mile in the European countries and New South Wales, for the capacity of each unit of rolling stock is about the same. It would be misleading, however, to make such a comparison with British India, because of the large proportion of narrow gauge stock; and it would be very misleading to make a comparison between the United States and other countries. As will be shown in the section on Rolling Stock, the average freight car of the United States probably carries three times as much as the average freight car of Europe. On that assumption the freight equipment of the United States is much more per mile than that of France or Germany, but only

TABLE III.—*Rolling Stock in Several Countries—Absolute and per* 100 *Miles of Railway.*

Year	1898. United States.	1897. United Kingdom.	1897. France.	1897-98. Germany.	India.	1900. New South Wales.
Locomotives	36,234	19,479	10,611	16,884	4,537	489
Locomotives per 100 miles	20	91	42	57	19	17
Passenger cars	33,595	44,053	27,179	33,664	13,263	1,025
Passenger cars per 100 miles	18	206	107	114	55	37
Freight cars	1,292,579	664,833	279,534	361,506	89,108	10,929
Freight cars per 100 miles	700	3,044	1,096	1,230	375	390

about two-thirds that of the United Kingdom. German statistics often give not only the number of cars but also the number of axles. Even that does not give an exact basis of comparison, for the load on one axle is considerably greater in the United States than in any other country. The same is true, though in a less degree, of comparisons between locomotives. By combining Table II. and Table III. a notion may be obtained of the work done by a unit of equipment in various countries.

Table IV. shows the capital of the railways of several countries, absolute and per mile, giving the latest figures available at the time of writing, which will, however, suffice for the purposes for which it is inserted here, namely, to give a comparison at a particular period.

TABLE IV.—*Capital of the Railways of Certain Countries.*

(Great Britain from Board of Trade Returns; United States from Interstate Commerce Commission; other countries from the *Archiv für Eisenbahnwesen.*)

Country.	Year.	Total.	Per Mile.
Germany	1897–98	£580,225,000	£19,927
Austria	1897	230,053,000	21,260
Hungary; State roads	1897	84,970,000	17,900
France; Main lines	1897	640,186,000	24,790
United Kingdom	1898	1,134,468,462	52,400
United States	1898	2,221,470,000	12,390
British North America	1898	193,343,000	11,470
New South Wales	1898	38,424,000	14,280

Trans-Continental Railways.—A railway line across North America was first completed in 1869, when the Union Pacific, building from the Missouri river at Omaha (1400 miles west of New York), met the Central Pacific, which built from San Francisco eastwards, making a line 1848 miles long through a country then for the most part uninhabited. This was followed by the Southern Pacific in 1881, from San Francisco to New Orleans, 2489 miles; the Northern Pacific, from St Paul to Portland, Or., in 1883; the Atchison, Topeka, and Santa Fé, from Kansas City to San Diego; and the Great Northern, from St Paul to Seattle and New Westminster in 1893. Meanwhile the Canadian Pacific, a true trans-continental line, was built from Montreal, on Atlantic tide-water, to the Pacific at Vancouver, 2906 miles. But these lines have been dwarfed since 1891 by the Siberian Railway, built by the Russian Government entirely across the continent of Asia from Cheliabinsk (1769 miles by rail east of St Petersburg) to Vladivostok, a distance of 4073 miles, with a branch about 500 miles long to the Chinese ports Dalny and Port Arthur. The part of this railway in China had construction trains running over its full length early in 1902, but was not to be ready for public traffic until much later; and there remains to be built about 170 miles in very difficult country around the south end of Lake Baikal, communication being now maintained by ferry-boats, which convey all the carriages of a train across the lake, more than 40 miles, when the ice permits. Besides its connexion with the Chinese Eastern Railway, the Siberian Railway reaches a navigable branch of the Amur at Sryetensk, from which a large fleet of light-draught steamboats maintain communication with Vladivostok by means of a railway from that place north-east 478 miles to the Amur at Khabarovsk. The extent of country made accessible by the Siberian Railway is greatly increased by the thousands of miles of navigable rivers which it crosses—the Ob, the Tom, the Irtysh, and the Yenisei west of Lake Baikal, and the Sungari in Manchuria. Down to 1902 the new railway had brought about a million Russian immigrants into Siberia, and a beginning had been made towards exploiting the coal, copper, and other mines of the country. Mr. Rhodes's project of the Cape-to-Cairo Railway, if ever realized, is likely to serve almost exclusively for local and not for trans-continental traffic, because the sea affords a very much cheaper and, for nearly all purposes, a much better route. A trans-continental line was long ago

undertaken across South America from Buenos Aires to the Chilian coast. The continent here is only about 900 miles wide. A short section remains to be built, but that is over and through the Andes, and will be very costly. (H. G. P.)

Railway Economics and Legislation.

It was at one time an axiom of law and of political economy that prices should be determined by free competition. But in the development of the railway business it soon became evident that no such dependence on free competition was possible, either in practice or in theory. This difficulty is not peculiar to railways; but it was in the history of railway economy and railway control that certain characteristics which are now manifesting themselves in all directions where large investments of fixed capital are involved were first brought prominently to public notice.

For a large number of those who use a railway, competition in its more obvious forms does not and cannot exist. Independent carriers cannot run trains over the same line and underbid one another in offering transportation services. It would be practically impossible for a line thus used by different carriers to be operated either with safety, or with economy, or with the advantage to the public which a centralized management affords. It is equally impossible for the majority of shippers to enjoy the competition of parallel lines. Such duplication of railways involves a waste of capital. If parallel lines compete at all points, they cause ruin to the investors. If they compete at some points and not at others, they produce a discrimination or preference with regard to rates and facilities, which builds up the competitive points at the expense of the non-competitive ones. Such partial competition, with the discrimination it involves, is apt to be worse for the public than no competition at all. It increases the tendency, already too strong, towards concentration of industrial life in large towns. It produces an uncertainty with regard to rates which prevents stability of prices, and is apt to promote the interests of the unscrupulous speculator at the expense of those whose business methods are more conservative. So marked are these evils that such partial competition is avoided by agreements between the competing lines with regard to rates, and by divisions of traffic, or pools, which shall take away the temptation to violate such rate agreements. The common law has been somewhat unfavourable to the enforcement of such agreements, and statutes in the United States, both local and national, have attempted to prohibit them; but the public advantage from their existence has been so great as to render their legal disabilities inoperative. In those parts of the continent of Europe where railways are owned and administered by State authority, the necessity for such agreements is frankly admitted.

But if rates are to be fixed by agreement, and not by competition, what principle can be recognized as a legitimate basis of railway rate-making? The first efforts at railway legislation were governed by the equal mileage principle; that is, the attempt was made to make rates proportionate to the distance. It was, however, soon seen that this was inadmissible. So much of the expense of the handling, both of freight and of passengers, was independent of the length of the journey that a mileage rate sufficiently large for short distances was unnecessarily burdensome for long ones, and was bound to destroy long-distance traffic, if the theory were consistently applied. The system has been retained in large measure in passenger business, but only because of the conflict which inevitably occurs between the authorities and the passengers with regard to the privilege of breaking and resuming a journey when passenger rates are arranged on any other plan. In freight schedules it has been completely abandoned.

A somewhat better theory of rate regulation was then framed, which divided railway expenditures into movement expense, connected with the line in general, and terminal expense, which connected itself with the stations and station service. Under this system each consignment of freight is compelled to pay its share of the terminal expense, independently of distance, *plus* a mileage charge proportionate to the length of the journey or haul. There has been also a further attempt in England to divide terminal charges into station and service terminals, according to the nature of the work for which compensation is sought. But none of these classifications of expense reaches the root of the matter. A system of charges which compels each piece of traffic to pay its share of the charges for track and for stations overlooks the fundamental fact that a very large part of the expenses of a railway—more than half—is not connected either with the cost of moving traffic or of handling traffic at stations, but with the cost of maintaining the property as a whole. Of this character are the expenditures necessary for maintenance of way, for general administration, and for interest on capital borrowed, which are almost independent of the total amount of business done, and quite independent of any individual piece of business. To say that all traffic must bear its share of these interest and maintenance charges is to impose upon the railways a rate which would cut off much of the long-distance traffic, and much of the traffic in cheap articles, which is of great value to the public, and which, from its very magnitude, is a thing that railways could not afford to lose. It is also a fact that with each recurring decade these general expenses (also called indirect, undistributed, or fixed charges) have an increased importance as compared with the particular (direct, distributed, or operating) expense attaching naturally to the particular portions of the traffic. For with increased density of population it becomes profitable to make improvements on the original location, even though this may involve increased charges for interest and for some parts of its maintenance, for the sake of securing that economy of operation, through larger train-loads, which such an improved location makes possible.

Whatever the ostensible form of a railway tariff, the contribution of the different shipments of freight to these general expenses is determined on the principle of charging what the traffic will bear. Under this principle, rates are reduced where the increase of business which follows such reduction makes the change a profitable one. They are kept relatively high in those cases where the expansion of business which follows a reduction is small, and where such a change is therefore unprofitable. This theory of charging what the traffic will bear is an unpopular one, because it has been misapplied by railway managers and made an excuse for charging what the traffic will not bear. Rightly applied, however, it is the only sound economic principle. It means taxation according to ability—that ability being determined by actual experiment.

In the practical carrying out of this principle, railways divide all articles of freight into classes, the highest of which are charged two or three, or even four, times the rates of the lowest. This classification is based partly upon special conditions of service, which make some articles more economical to carry than others (with particular reference to the question whether the goods are offered to the companies in car-loads or in small parcels), but chiefly with regard to the commercial value of the article, and its consequent ability to bear a high charge or a low one. For each of these classes a rate-sheet gives the actual rate-charge per unit of weight between the various

stations covered by the tariff. This rate increases as the distance increases, but not in equal proportion; while the rates from large trade centres to other trade centres at a great distance are not higher than those to intermediate points somewhat less remote; if the law permits, there is a tendency to make them actually a little lower. Besides the system of charges thus prescribed in the classification and rate sheet, each tariff provides for a certain number of special rates or charges made for particular lines of trade in certain localities, independently of their relation to the general system. If these special rates are published in the tariff, and are offered to all persons alike, provided they can fulfil the conditions imposed by the company, they are known as commodity rates, and are apparently a necessity in any scheme of railway charges. If, however, they are not published, and are given to certain persons as individual favours, they become a prolific source of abuse, and are quite indefensible from the standpoint of political economy.

While the superficial appearance of the railway tariff is different for different countries, and sometimes for different parts of the same country, the general principles laid down are followed in rate-making by all well-managed lines, whether State or private. It is a mistake to suppose that the question of public or private ownership will make any considerable difference in the system of rate-making adopted by a good railway. A State system will be compelled, by the exigencies of the public treasury, to arrange its rates to pay interest on its securities; a private company will generally be prevented, by the indirect competition of railways in other parts of the country which it serves, from doing very much more than this. The relative merit of the two systems depends upon the question how we can secure the best efficiency and equity in the application of the principles thus far laid down. There are three different systems of control:—

1. *Private operation, subject only to judicial regulation*, was exemplified most fully in the early railway history of the United States. Until 1870 railway companies were almost free from special Acts of control; and, in general, any company that could raise or borrow the capital was allowed to build a railway wherever it saw fit. In the United Kingdom there was almost as much immunity from legislative interference with charges, but the companies were compelled to secure special charters, and to conform to regulations made by the Board of Trade in the interests of public safety. The advantage of this relatively free system of railway building and management is that it secures efficient and progressive methods. Most of the improvements in operation and in traffic management have had their origin in one of these two countries. The disadvantage attendant upon this system is that the courts are reluctant to exercise the right of regulation, except on old and traditional lines, and that in the face of new business methods the public may be inadequately protected. There is also this further disadvantage, that in the gradual progress of consolidation railway companies take upon themselves the aspect of large monopolies, of whose apparently unrestricted power the public is jealous. As a result of these difficulties there has been, both in the United Kingdom and in the United States, a progressive increase of legislative interference with railways. In the former the Railway and Canal Traffic Act of 1854 specially prohibited preferences, either in facilities or in rates. The Regulation of Railways Act of 1873 provided for a Railway Commission, which should be so constituted as to take cognizance of cases on the investigation of which the courts were reluctant to enter. Finally, the legislation of 1888 put into the hands of a reorganized Railway Commission and of the Board of Trade powers none the less important in principle because their action has been less in its practical effect than the advocates of active control demanded. In the United States the years from 1870 to 1875 witnessed sweeping and generally ill-considered legislation ("Granger" Acts) concerning railway charges throughout the Mississippi valley; while the years from 1884 to 1887 were marked by more conservative, and for that reason more enforceable, Acts, which culminated in the Interstate Commerce Act, prohibiting personal discrimination and gradually restricting discrimination between places, and providing for a National Commission of very considerable power—not to speak of the pooling clause, which was extraneous to the general purpose of the Act, and has tended to defeat rather than strengthen its operation. An increased amount of attention has also been paid, both by the states and the government, to laws in the interests of public safety.

2. *Operation by private companies, under specific provisions of the Government authorities with regard to the method of its exercise*, has been the policy consistently carried out in France, and less systematically and consistently in other countries under the domination of the Latin race. It was believed by its advocates that this system of prescribing the conditions of construction and operation of lines could promote public safety, prevent waste of capital, and secure passengers and shippers against extortionate rates. These expectations have been only partially fulfilled. Well trained as was the civil service of France, the effect of this supervision in deadening activity was sometimes more marked than in its effect in preventing abuse. Moreover, such a system of regulation almost necessarily carries with it a guarantee of monopoly to the various companies concerned, and not infrequently large gifts in the form of subsidies, for without such aid private capital will not submit to the special burdens involved. These rights, whether of monopoly or of subsidy, form a means of abuse in many directions. Where the Government is bad, they are a fruitful source of corruption; even where it is good, they enable the companies to drive hard bargains with the public, and prevent the expected benefits of official control from being realized.

3. *State operation and ownership* is a system which originated in Belgium at the beginning of railway enterprise, and has been consistently carried out by the Scandinavian countries and by Hungary. Since 1860 it has been the policy of Australia. It has generally come to be that of Germany and, so far as the finances of the countries allow, of Austria and Russia; British India also affords not a few examples of the same method. The theory of State ownership is excellent. So large a part of the railway charge is of the nature of a tax, that there seem to be *à priori* reasons for leaving the taxing powers in the hands of the agents of the Government. In practice its operation is far more uncertain. Whether the intelligence and efficiency of the officials charged by the State with the handling of its railway system will be sufficient to make them act in the interest of the public as fully as do the managers of private corporations, is a question whose answer can only be determined by actual experience in each case. If they fail to have these qualities, the complete monopoly which a Government enjoys, and the powers of borrowing which are furnished by the use of the public credit, increase instead of diminishing the danger of arbitrary action, unprogressiveness, and waste of capital. Even in matters like public safety it is by no means certain that Government authorities will do so well as private ones. The question is one which practical railway men have long since ceased to argue on general principles: they recognize that the answer depends upon the respective degree of talent and integrity which characterize the busi-

ness community on the one hand and the Government officials on the other.

Authorities.—On economics of construction and of operation, see Wellington, *The Economic Theory of Railway Location*, 5th edition, New York, 1896. On principles governing railway rates in general, and specifically in England, see Acworth, *The Railways and the Traders*. London, 1891. On comparative railway legislation and the principles governing it, see Hadley, *Railroad Transportation; Its History and Its Laws*, New York, 1885. On the history of railway legislation in England, see Cohn, *Untersuchungen über die Englische Eisenbahnpolitik*, Leipzig, 1874–83. On practice concerning rates in continental Europe, see Ulrich, *Das Eisenbahntarifwesen*, Berlin, 1886. (Since this was published, Continental passenger rates have fallen. The French translation—Paris, 1898—gives Russian tariffs.) (A. T. H.)

British Railway Legislation.

Construction.

The first thing a railway company in Great Britain has to do is to obtain a special or private Act of Parliament authorizing the construction of the line. Not that the mere laying or working of a railway requires parliamentary sanction, so long as the work does not interfere with other people's rights and interests. An example of a railway built without any legislative authority is the little mountain railway from Llanberis to the summit of Snowdon, which was made by the owner of the land through which it passes. Such a railway has no statutory rights and no special obligations, and the owner of it is liable to be sued for creating a nuisance if the working of the line interferes with the comfort of those residing in the neighbourhood. When, however, a company desires to construct a line on a commercial scale, to acquire land compulsorily, to divert rivers and streams, to cross roads either on the level or by means of bridges, to pass near houses, to build tunnels or viaducts, and to execute all the other works incidental to a railway, and to work the line when completed without interference, it is essential that the authority of Parliament should be obtained. The company therefore promotes a Bill, which is considered first by select committees of the two Houses of Parliament, and afterwards by the two Houses themselves, during which period it faces the opposition, if any, of rival concerns, of local authorities, and of hostile landowners. If this is successfully overcome, and the proposals meet with the approval of Parliament, the Bill is passed, and after securing the Royal Assent, becomes an Act of Parliament. The company is then free to proceed with the work of construction, and at once becomes subject to various general Acts, such as the Companies Clauses Act, which affects all joint-stock companies incorporated by any Special Act; the Land Clauses Act, which has reference to all companies having powers to acquire land compulsorily; the Railway Clauses Act, which imposes certain conditions on all railways alike (except light railways); the various Regulation of Railways Acts; the Carriers Protection Act; Acts for the conveyance of mails, parcels, troops; Acts relating to telegraphs to the conveyance of workmen, and to the housing of the labouring classes; and several others which it is unnecessary to specify. From the early days of railways Parliament has also been careful to provide for the safety of the public by inserting in the general or special Acts definite conditions, and by laying upon the Board of Trade the duty of protecting the public using a railway.

Inspection.

The first Act which has reference to the safety of passengers is the Regulation of Railways Act of 1842, which obliges every railway company to give notice to the Board of Trade of its intention to open the railway for passenger traffic, and places upon that public department the duty of inspecting the line before the opening of it takes place. If the officer appointed by the Board of Trade should, after inspection of the railway, report to the department that in his opinion "the opening of the same would be attended with danger to the public using the same, by reason of the incompleteness of the works or permanent way, or the insufficiency of the establishment for working such railway," it is lawful for the department to direct the company to postpone the opening of the line for any period not exceeding one month at a time, the process being repeated from month to month as often as may be necessary. The company is liable to a fine of twenty pounds a day if it should open the line in contravention of such order or direction. The inspections made by the officers of the Board of Trade under this Act are very complete: the permanent way, bridges, viaducts, tunnels, and other works are carefully examined; all iron or steel girders are tested; stations, including platforms, stairways, waiting-rooms, etc., are inspected; and the signalling and "interlocking" are thoroughly overhauled. A code of requirements in regard to the opening of new railways has been drawn up by the department for the guidance of railway companies, and as the special circumstances of each line are considered on their merits, it rarely happens that the department finds it necessary to prohibit the opening of a new railway. The Regulation of Railways Act of 1871 extends the provisions of the above Act to the opening of "any additional line of railway, deviation line, station, junction, or crossing on the level" which forms a portion of or is connected with a passenger railway, and which has been constructed subsequently to the inspection of it. This Act further defines the duties and powers of the inspectors of the Board of Trade, and also authorizes the Board to dispense with the notice which the previous Act requires to be given prior to the opening of any railway or part of it.

It may be remarked that neither of these Acts confers on the Board of Trade any power to inspect a railway after it has once been opened, unless and until some addition or alteration, such as defined in the last-named Act, has been made. When a line has once been inspected and passed, it lies with the company to maintain it in accordance with the standard of efficiency it originally possessed, but no express statutory obligation to do so is imposed upon the company, and whether it does so or not the Board of Trade cannot interfere.

Inquiries into accidents.

The Act of 1871 further renders it obligatory upon every railway company to send notice to the Board of Trade in the case of (1) any accident attended with loss of life or personal injury to any person whatsoever; (2) any collision where one of the trains is a passenger train; (3) any passenger train or part of such train leaving the rails; (4) any other accident likely to have caused loss of life or personal injury, and specified on that ground by any order made from time to time by the Board of Trade. The department is authorized, on receipt of such report, to direct an inquiry to be made into the cause of any accident so reported, and the inspector appointed to make the inquiry is given power to enter any railway premises for the purposes of his inquiry, and to summon any person engaged upon the railway to attend the inquiry as a witness, and to require the production of all books, papers, and documents which he considers important for the purpose. The inspector, after making his investigation, is required to make a report to the Board of Trade as to the causes of the accident and the circumstances attending the same, with any observations on the subject which he deems right, and the Board "shall cause every such report to be made public in such manner as they think expedient." The usual mode of publishing such reports is to forward them to railway companies concerned, as well as to the press, and on application to any one else who is interested. The reports are subsequently included in a Blue-book and presented to Parliament. It should be noted that although the inspecting officer may in his report make any recommendations that he may think fit with a view to guarding against any similar accident occurring in the future, no power is given to the Board of Trade, or to any other authority, to compel any railway company to adopt such recommendations. This omission is sometimes held to be an error, but as a fact it is an advantage. The moral effect of the report, with the criticisms of the company's methods and recommendations appended thereto, is great, and it rarely happens that a company refuses to adopt, or at any rate to test, the recommendations so made. If on the other hand the company is of opinion that the suggestions of the inspecting officer are not likely to prove beneficial, or are for any reason unadvisable, it is at liberty to reject them, the responsibility of doing so resting entirely upon itself. The effect of this latitude is to give the company ample discretion in the matter, and to enable the Act of Parliament to be administered and the object of it to be attained without undue interference.

Working.

In 1889 a very important Act was passed placing upon the Board of Trade the obligation to call upon railway companies throughout the United Kingdom (1) to adopt upon all passenger lines the "block" system of working; (2) to "interlock" their points and signals; (3) to fit all trains carrying passengers with some form of automatic continuous brake. Prior to this some companies had, to a certain extent, done these things, but few, if any, were completely equipped in these respects. A reasonable period was afforded them, according to circumstances, to comply with these requirements, and at the present time the work is practically complete. In this respect the lines of the United Kingdom are far ahead of those of any other country, and a diminution of accidents, particularly of collisions, has resulted therefrom. America is now following the lead thus set, and all the most important lines in the United States have adopted block working and interlocking, but a great deal still remains to be done. In certain respects, on the other hand, America has gone further than the United Kingdom, especially in the matter of automatic signalling, and in the operating of points and signals by electrical power or air-pressure instead of manual labour. In America, also, it is the custom to fit freight trains with an automatic continuous brake, whereas in the United Kingdom this appliance is required by law only in the case of passenger trains, and in fact is not fitted to goods and mineral trains except in one or two isolated instances.

The above-named Acts enable the Board of Trade to take all the necessary steps to ensure that the safety of passenger trains is sufficiently guarded. More recently legislation has been passed to safeguard the lives and interests of railway servants. In 1893 an Act was passed by Parliament giving the Board power to interfere if or when representations are made to them by or on behalf of any servant or class of servants of a railway company that the hours of work are unduly long, or do not provide sufficient intervals of uninterrupted rest between the periods of duty, or sufficient relief in respect of Sunday duty. In such cases the company concerned may, after inquiry, be called upon to submit such a schedule of the hours during which the man or men are employed as will bring those hours within limits which appear to the department reasonable. In the event of the company failing to comply with the demands of the department, the latter is empowered to refer the case to the Railway and Canal Commissioners, who form a special Court constituted by the Railway and Canal Traffic Act of 1888, for deciding, among other things, questions relating to rates and charges, for protecting traders from undue charges and undue preference, for regulating questions of traffic, and for deciding certain disputes between railway companies and the public. The Commissioners are then empowered to deal with the matter, and if "a railway company fail to comply with any order made by the Railway and Canal Commissioners, or to enforce the provisions of any schedule" approved by them, it is liable to a fine of a hundred pounds for every day during which the default continues. This Act has been the means of effecting a considerable reduction in the hours worked by railway men on certain railways, and no case has yet arisen in which a reference to the Commissioners has been necessary. Such modifications of the hours of work have not only been beneficial to the men, but have improved the discipline of the staff and the punctuality and regularity of the train service, particularly in respect of the goods trains.

Hours of labour.

The Notice of Accidents Act of 1884, which obliges employers of labour to report to the Board of Trade, when "there occurs in any employment" as defined by the schedule of the Act, "any accident which causes to any person employed therein, either loss of life or such bodily injury as to prevent him on any one of the three working days next after the occurrence of the accident from being employed for five hours on his ordinary work," affects railways in course of construction, but not, as a rule, otherwise.

Although the administration of the above-mentioned Acts of Parliament has had a beneficial effect upon the safety of the public, and has enabled an enormous volume of traffic to be handled with celerity, punctuality, and absence of risk, it has during recent years come to notice that the number of casualties among railway servants is still unduly great, and in 1899 a Royal Commission was appointed to investigate the causes of the numerous accidents, fatal and non-fatal, to railway men. As a consequence of the report of this Commission the Railway Employment (Prevention of Accidents) Act of 1900 was passed, putting upon the Board of Trade the duty of making "such rules as they think fit with respect to any of the subjects mentioned in the schedule to this Act, with the object of reducing or removing the dangers and risks incidental to railway service." Rules may also be made in respect to other matters besides those mentioned in the schedule, and companies may be called upon to adopt or reject, as the case may be, any appliance, the use or disuse of which may be considered desirable in the interest of the men. Before, however, the rules so made become binding upon the companies, the latter have the right of appealing against them to the Railway Commissioners. Failure to comply with any of the rules renders a company "liable for each offence, on conviction under the Summary Jurisdiction Acts, to a fine not exceeding fifty pounds, or in the case of a continuing offence to a fine not exceeding ten pounds for every day during which the offence continues after conviction." Rules drafted by the Board of Trade under this Act came into force on the 8th of August 1902, the subjects referred to being (1) labelling of waggons; (2) movements of waggons by propping and tow-roping; (3) power-brakes on engines; (4) lighting of stations and sidings; (5) protection of points, rods, &c.; (6) construction and protection of gauge-glasses; (7) arrangement of tool-boxes, &c., on engines; (8) provision of brake-vans for trains upon running lines beyond the limits of stations; (9) protection to permanent-way men when relaying or repairing permanent way. The final settlement of a rule requiring brake-levers to be fitted on both sides of goods-waggons was, however, deferred, owing to objections raised by certain of the railway companies.

Safety of servants.

Other Acts which are of importance in connexion with accidents are the Accidents Compensation Act of 1846; the Employers' Liability Act of 1880, and the Workmen's Compensation Act of 1897.

The public Acts of Parliament referring to British railways are collected in BIGG's *General Railway Acts.* (H. A. Y.)

STATISTICS OF ACCIDENTS.

The railway companies of Great Britain are, as stated above, obliged by the Act of 1871 to give the Board of Trade notice of certain kinds of accidents occurring on their lines. Some of these kinds are explicitly mentioned in the Act, but with regard to requiring notice of others, the Board of Trade has a discretionary power. This it has exercised from time to time, and its general orders now in force specify, as requiring notice, accidents (1) as regards the locomotive power and rolling-stock, such as the bursting of engine-boilers and failures of axles, wheels, tyres, and other parts of locomotive engines, tenders, or vehicles; (2) as regards the permanent way and works, such as the failure of rails, bridges, tunnels, viaducts, &c.; and (3) miscellaneous accidents to rolling-stock and permanent way, such as trains coming into collision with the gates of level-crossings and other obstructions on the lines, &c.

Accidents to trains, such as collisions and derailments, may be divided into two classes, namely, those caused by defective construction or maintenance of the permanent way, works, and rolling-stock, and those caused by mistakes or negligence on the part of the employés of the railway companies; to these must be added a few cases that arise from unavoidable causes, such as obstacles falling on the rails, or the expansion of rails through excessive heat. The improvements in safety appliances on the railways have much reduced the number of serious accidents to trains, and the following summary (Table V.) of the cases into which it was found necessary to order inquiries by the inspecting officers of the Board of Trade, divided into periods of five years, shows to what extent such reduction has taken place since 1871:—

Accidents to trains.

TABLE V.

Number of inquiries held by inspecting officers of the Board of Trade into accidents to trains during successive periods of five years, and total number of miles open for traffic at end of each period of five years.

Period.	Number of Inquiries.	Miles open at End of Period.
1871 to 1875	996	16,658
1876 ,, 1880	621	17,933
1881 ,, 1885	488	19,169
1886 ,, 1890	303	20,073
1891 ,, 1895	266	21,174
1896 ,, 1900	290	21,855

These accidents may be divided into the classes shown in Table VI.:—

TABLE VI.

Class of Accident.	1871–1875.	1876–1880.	1881–1885.	1886–1890.	1891–1895	1896–1900.
A. From engines or vehicles meeting with obstructions, or leaving the rails in consequence of obstructions, or from defects in connexion with the permanent way or works	96	86	78	44	40	27
B. From boiler explosions, failures of axles, wheels, or tyres, or from other defects in the rolling-stock	88	60	40	26	18	9
C. From trains entering stations at too great speed	16	25	40	35	44	30
D. From collisions between engines and trains following one another on the same line of rails, excepting at junctions, stations, or sidings	68	27	23	8	13	18
E. From collisions at junctions	107	67	47	27	26	38
F. From collisions within fixed signals at stations or sidings	394	223	192	112	101	125
G. From collisions between engines or trains meeting in opposite directions	23	9	7	19	4	2
H. From collisions at level-crossings of two railways	5	1	..	..	..	1
I. From engines or trains being wrongly run or turned into sidings or otherwise, through facing-points	124	87	45	20	11	8
J. On inclines (trains)	46	33	10	10	5	11
K. Miscellaneous	29	3	6	2	4	21

The principal improvements which have tended to the reduction of most of the classes of accidents shown in the preceding table

are the adoption of the block system, of interlocking points and signals, and of continuous automatic brakes, all of which the Board of Trade was empowered to order by the Regulation of Railways Act of 1889.

The circumstances which contributed to the accidents inquired into are shown in the following summary (Table VII.); but it must be borne in mind that as a large number of the accidents arose from more than one of the circumstances enumerated, this summary shows an excess over the actual number of accidents :—

TABLE VII.

Circumstances contributing to the Accidents.	1871–1875.	1876–1880.	1881–1885.	1886–1890.	1891–1895.	1896–1900.
Defective rolling-stock or failures of apparatus of rolling-stock . . .	174	232	156	77	39	17
Defective road or works signalling and safety apparatus, &c.	412	276	140	80	53	34
Insufficient or defective accommodation for the requirements of the traffic .	120	51	20	5	6	8
Insufficient establishment, long hours, inexperienced servants, or want of proper supervision	187	125	20	31	69	38
Defective systems for securing intervals between trains	212	89	49	35	25	11
Negligence, want of care, and mistakes of officers and servants	740	459	360	233	220	244
Foggy or stormy weather	82	47	39	31	25	30

In the accidents that occurred to trains, the loss of life and personal injury to passengers was as shown in Table VIII :—

TABLE VIII.

Year.	Number of Passengers Killed and Injured from Accidents to Trains.		Number of Passenger Journeys (exclusive of Journeys by Season-Ticket Holders).	Proportion of Killed and Injured to Number carried.	
	Killed.	Injured.		Killed.	Injured.

1892	21	601	864,435,388	1 „ 41,163,589	1 „ 1,438,328
1893	17	484	873,177,052	1 „ 51,363,356	1 „ 1,804,084
1894	16	347	911,412,926	1 „ 56,963,307	1 „ 2,626,550
1895	5	399	929,770,909	1 „ 185,954,182	1 „ 2,330,253
1896	5	388	980,339,433	1 „ 196,067,887	1 „ 2,526,648
1897	18	324	1,030,420,201	1 „ 57,245,567	1 „ 3,180,309
1898	25	632	1,062,911,116	1 „ 42,516,445	1 „ 1,681,821
1899	14	693	1,106,691,991	1 „ 79,049,428	1 „ 1,596,958
1900	16	863	1,142,276,686	1 „ 71,392,293	1 „ 1,323,611
1901	0	476	1,172,395,900	...	1 „ 2,463,017

From this table it will be seen that no deaths occurred to passengers from collisions, derailments, &c., on the railways of the United Kingdom in the year 1901. The two accidents involving the greatest loss of life in the period covered by the table were (1) the Tay Bridge disaster, which occurred in 1879, when, owing to the failure of the bridge while a train was passing over it during a gale, the train was thrown into the water and 73 passengers lost their lives; and (2) the terrible accident at Armagh in 1889, when the rear portion of a passenger train ran back down an incline and came into collision with a following passenger train, causing the death of 80 passengers and injury to 262 others.

Accidents to passengers.

Accidents to passengers from causes other than accidents to the trains in which they were travelling for the years 1875, 1880, 1885, and 1890–1901 are shown in Table IX :—

TABLE IX.

Year.	From Accidents in connexion with the Movement of Trains, Railway Carriages, &c.		From Accidents on Railway Premises not in connexion with the Movement of Trains, &c.		Total.

[1] *Note.*—In the year 1896 an Order of the Board of Trade under the Regulation of Railways Act 1871, laying down more stringent regulations for reporting non-fatal accidents, came into force. By this Order companies are required to report *all* cases of injury to passengers. The principal causes of accidents to passengers in this class are from falling between trains and platforms or on the ballast when entering or alighting from trains in motion, from falling off platforms or out of trains, from being run over when crossing the lines at stations, and from falling when ascending or descending steps at stations.

Total risk to passengers.

Taking the figures for 1901, the total risk to passengers from the time they entered the premises of the railway company until their departure therefrom was—

Fatal accidents . . .	1 in 7,420,227
Non-fatal accidents . . .	1 „ 415,007

This calculation, like those previously given in the above tables, does not take into account the journeys made by holders of season-tickets, of which 1,879,136 were issued in 1901, as the number of journeys made by the holders cannot be estimated. It is obvious that if an accurate estimate of these journeys could be made, a large increase in the number of passenger journeys would be shown, with a corresponding benefit to the passenger when calculating his risk of accident.

Accidents to employés.

Notwithstanding the measures taken by the railway companies for the protection of their servants when on duty, and the efforts of the Government to reduce the risks incurred by the men, the number of accidents of this class continue to be high. The effects of the Rules issued by the Board of Trade under the Railway Employment (Prevention of Accidents) Act of 1900 will, it is hoped, however, tend to the reduction of these accidents. The principal risks incurred by the men are those entailed by shunting operations, and by the work of repairing or inspecting the permanent way while the traffic is in progress. The Rules issued by the Board of Trade are intended to minimize these risks. Table X. shows the number of accidents occurring to servants of the companies in traffic operations, but a large number of slight accidents occur from causes in which the movement of the traffic is not concerned, and these are not included in the two following tables (Tables X. and XI.)

The number of persons employed by the railway companies is known accurately for certain years only, namely, 1874, 1884, 1889, 1895, 1898, and 1901, but for the purposes of these tables it has been estimated for the other years taken (estimated figures being printed in italics).

The apparent sudden rise of the injuries in 1896 is due to the effect of the Board of Trade Order of October 1895, referred to in the note to Table IX. From the commencement of 1896 the companies were required to report non-fatal accidents to their servants whenever they were such as to prevent the servant injured, on any one of the three working days next after the accident, from being employed for five hours on his ordinary work.

TABLE X.

TABLE XII.

Year.	Number of Persons Killed at Level-Crossings.	Number of Persons Injured at Level-Crossings.	Year.	Number of Persons Killed at Level-Crossings.	Number of Persons Injured at Level-Crossings.
1875	66	41	1895	65	33
1880	74	30	1896	51	27
1885	58	21	1897	80	25
1890	83	35	1898	64	27
1891	66	31	1899	60	22
1892	77	21	1900	63	35
1893	55	30	1901	55	26
1894	80	31			

The number of accidents to persons making use of level-crossings over the railways does not show any appreciable diminution in the 25 years from 1875 to 1901, although improvements have been made by the provision of foot-bridges or subways at many busy places where the level-crossings were previously the only means of crossing the line, and in other cases by the provision of signals interlocked with the gates. The numbers of persons killed and injured while passing over level-crossings in certain years are shown in Table XII.

Other accidents.

The remaining classes of accidents on railways are those which occur to trespassers on the railways, of whom 282 were killed and 154 injured in 1901; those which occur to persons transacting business at railway stations and sidings (principally traders' servants engaged in obtaining or delivering goods), 17 of whom were killed and 122 injured in 1901; and those that occur to persons who can neither be described as being on business or trespassing, of whom 24 were killed and 28 injured in 1901. In addition, 144 persons committed suicide by placing themselves in front of trains in 1901, and 17 persons were injured while apparently attempting to commit suicide in the same manner. The number of suicides is slightly in excess of the average number for preceding years.

Accidents in United States.

In the United States of America the figures of accidents are now reported under an Act of Congress, approved on the 3rd March 1901, which requires that "common carriers engaged in interstate commerce make full reports of all accidents to the Interstate Commerce Commission by a monthly report under oath, of all collisions of trains, or where any train or part of a train leaves the track, and of all accidents which may occur to its passengers or employés while in the service of such common carrier and actually on duty." The reports rendered in accordance with this Act are apparently more complete than those hitherto furnished, but the requirements of the Act do not include accidents at level-crossings. For the second six months of 1901 it appears that 108 passengers were killed and 1999 injured in accidents to trains, and 87 were killed and 1510 injured in other accidents. The number of employés killed was 1343, and 17,213 were injured. Compared with the accidents in the United Kingdom for the same period of six months the relative figures are given in Table XIII. :—

TABLE XIII.

	United States of America.		United Kingdom.	
	Killed.	Injured.	Killed.	Injured.
Passengers . .	195	3,509	80	1299
Servants . . .	1343	17,213	286	2178

The latest proportions given for the United States are for the year ending 30th June 1900, as shown in the Report of the Interstate Commerce Commission ; these are compared with the British figures for the year ending 31st December 1900 in Table XIV :—

TABLE XIV.

	United States.		United Kingdom.	
	Killed.	Injured.	Killed.	Injured.
Passengers: Proportion of killed and injured from accidents in connexion with the movement of trains to number of passenger journeys .	1 in 2,316,648	1 in 139,740	1 in 8,461,309	1 in 470,848
Servants: Proportion of killed and injured to numbers employed	1 in 399	1 in 26	1 in 916	1 in 116

The differences between the mileage of the railways, the numbers of passengers carried, and the numbers of employés in the two countries in the year 1900 are shown in Table XV. It will

TABLE XV.

	United States. Year ending 30th June 1900.	United Kingdom. Year ending 31st December 1900.
Mileage of railways . .	193,345	22,078
Number of passengers carried in 12 months . . .	576,865,230	1,142,276,686
Number of employés . .	1,017,653	575,834

be noticed that while the mileage and number of employés is higher in the United States than in the United Kingdom, the number of passengers carried is higher in the United Kingdom.

The number of persons killed and injured at level-crossings (not including those described as employés and trespassers) was 558 killed and 1090 injured in the year ending 30th June 1900, as against 59 killed and 29 injured in the same period in the United Kingdom. (H. A. Y.)

Financial Organization.

Before considering the general method of financial organization of railway companies, it is important to note the attitude taken up by the State toward their construction. In the United States public policy encourages the free building of lines by providing, under general laws, that any body of citizens may become incorporated in order to locate a railway, expropriate the necessary land, and proceed with construction and operation, the sole preliminary being that evidence must be shown of *bona fides* by a most modest subscription of capital. The effect of this legislation has been to make the railway a highly competitive business, subject from the investor's point of view to the extra hazards which must necessarily attend on capital engaged in fierce competition. From the point of view of the public, the policy mentioned has resulted in the multiplication of lines, and consequent cheap rates of service, together with wide development of territory. In the other countries of the world, where Government sanction has to be obtained for each undertaking, after proof not only of the ability of promoters to further the enterprise, but also of its present necessity and probable profitable conduct, the result is to surround capital with greater safeguards, but at some sacrifice of public benefit.

Some economic and *quasi*-political questions of importance may arise as the pressure of continuous high rates threatens to handicap a given region in the commercial race. For instance, in the United States the so-called "Granger" movement by the farmers was an important political force for some years. As the product of the farm depended largely on export values, it followed that the producers in the far interior found the cost of transportation to the sea a heavy burden, and largely disproportionate to the charge upon their competitors nearer to the shore. The progress of competition between rival carriers finally afforded a natural solution of this difficulty, by the reduction brought about in the rates of freight until a point was reached where it bore small proportion to the value of the article transported. But in cases where the same difficulty presents itself with a governmental concession practically precluding competition in rates, the aggrieved citizen naturally turns to the State for redress. This situation is beginning to assert itself in the Argentine Republic, in the British colonies, and to some extent in England itself.

The financial organization of railways began in various countries on substantially identical lines where it was proposed to build under private corporations. The shares of the corporation, after being paid for, carried no further liability, and the capital thus raised by subscription was augmented by borrowing under powers conferred by legislation or charter. Financial developments, however, soon assumed different forms in the different countries. In Great Britain and on the Continent borrowing powers were granted in very limited degree, generally for only one-fourth of the capital, and the debenture, or other obligation representing the authorized debt, became esteemed as a security of the highest character for investment. In the United States, on the other hand, borrowing powers were exercised for the most part under general laws and without limitation, so that often all the actual capital for building a railway was raised by forms of debt, while the share capital was issued solely for contractors' profit, and afforded no guarantee or margin for protection of indebtedness. The latter, therefore, became necessarily a much more precarious form of security for the investor, and large losses ensued to the public, both in the United States and in Europe, by reason of a confused belief that bonds or debentures indicated in each community an identical security, whereas the case was quite otherwise. In the former country, as has been above pointed out, the existing conditions of free competition call for the same examination on the part of an investor into individual conditions and environment as would be needful in respect to any other competitive industry. As rates have fallen, it has come to pass, particularly in the United States, that a complete rehabilitation of the plant has been gradually forced upon all the railways of the country. As the cost of hauling a large train-load is proportionately much less than of hauling a small one, the efforts of managers have been directed to increasing the carrying capacity of their trains. Herein is the explanation of the demands for new capital on a great scale by the older railway companies, which otherwise would presumably have reached the approximate limit of capital requirements. Hence, also, arose the policy now general in the United States of devoting a greater or less proportion of net revenues to payment for permanent improvements, instead of dividing them amongst the shareholders, a policy which has excited much criticism among British holders of American shares, but which American opinion has accepted as being for the best interest of shareholders, inasmuch as it gives assurance of greater stability under the stress of commercial fluctuations.

The tendency to amalgamate connecting systems of railway has had a marked stimulus in late years, by reason of the economies in operation and the advantages in conduct of traffic accruing from the extension of lines under one control. A certain jealousy is exhibited in some public quarters lest a centralized power thus vested over a great number of employés should lead to political abuses in a country where manhood suffrage prevails, but it is to the credit of those controlling such great executive powers that they seem to have been exercised, on the whole, wisely and in the public interest.

The peculiar status of the railway in modern life makes it of equal interest to the investor, the employé, and the political economist. It will be found that the best end is subserved for each of these by all development which tends to secure the maximum of service at the minimum of cost. By such influences will be created that volume and diversity of human industry which affords the best guarantee for the welfare of the individual and of the State. To this end the modern railway has proved itself an instrument of greater efficiency than any other, or perhaps than all others combined, as witness in the United States the growth in tonnage from 72,500,000 tons in 1870 to 975,000,000 tons in 1899, an increase of more than 1300 per cent. (J. GR.)

Railway Construction.

The principles of railway construction described in the ninth edition of this Encyclopædia remain true, and most of the essential facts there told need no modification. The changes are in detail.

Gauge. The tendency of time is to unify the gauge in each country and, generally speaking, in the world, though progress in that direction is not without interruption. In France, for example, at the end of 1898 there were 26,044 miles of railway, and of this amount 2490 miles were of narrow gauge, viz., 1 metre, 0·80 metre, and 0·60 metre, while 870 miles of narrow gauge were in course of construction. In British India about

42 per cent. of the total mileage is built to metre gauge or less, while the standard is 5 feet 6 inches, and the metre gauge lines are added to year by year. In the British colonies generally the gauge of 3 feet 6 inches may be called standard; but throughout the world the gauge of 4 feet 8½ inches is much more used than any other, and is increasing in far greater ratio. In North America 4 feet 8½ inches has become almost universal, except for small industrial railways and some short lines for local traffic, chiefly in mountainous country. The long lines of 3 feet gauge have generally been converted, or a third rail has been laid, permitting interchange of vehicles. The gauges of 5 feet and more have disappeared. A considerable number of lines use 4 feet 9 inches; but cars run freely from this gauge to the lines of 4 feet 8½ inches gauge, and back again. The commercial importance of this free interchange of cars is now the controlling fact in deciding on the gauge of a new railway, unless that railway is isolated by its geographical position. In Great Britain, also, the standard gauge is 4 feet 8½ inches, and there railways are now built to other gauges only under exceptional conditions; the "broad gauge" of 7 feet disappeared when the Great Western main line from London to Penzance was converted to standard gauge throughout its length on 20th–23rd May, 1892. In Ireland, however, the standard gauge is 5 feet 3 inches; and perhaps it would have been better for all the countries of Europe and America had 5 feet 6 inches, or even 6 feet, been made the standard, since the physical limits of the power of locomotives and the ultimate carrying capacity of cars would not have been reached so soon.

On the continent of Europe the standard gauge is generally 4 feet 8½ inches, but in Russia it is 5 feet, and in Spain 5 feet 5¾ inches. In France, as in the United States, there are many miles of track of 4 feet 9 inches gauge; but for traffic purposes this is not a break from the standard of 4 feet 8½ inches. The narrow-gauge railways of France have already been mentioned. In other Continental countries there is also an important mileage of metre gauge, and even narrower, on lines of local or secondary importance. India had, in March 1900, 13,670 miles of railway of 5 feet 6 inches gauge, 9496 miles of metre gauge, and 598 miles of special gauges; hence that country will supply valuable comparative data for the study of the efficiency and cost of working of broad and narrow gauge lines, and for such data the reader may be referred to the elaborate yearly reports of the Government of India. In Australia the disadvantages of a break of gauge are already felt. In New South Wales the standard is 4 feet 8½ inches; but in Victoria, on the south, it is 5 feet 3 inches; and in Queensland, on the north, it is 3 feet 6 inches. Obviously, as commerce between the states increases, the tax of a break of gauge at the frontier will become more serious, and for some years various commissioners of those states have urged the importance of one gauge. In New Zealand, Tasmania, and South Africa the gauge is 3 feet 6 inches. In Lower Egypt the standard is 4 feet 8½ inches, but the line into the Egyptian Sudan is 3 feet 6 inches. The reasons for building the Sudan line to this gauge were weighty and sufficient; but the time will come when a struggling commerce will be taxed with the perpetual costs of a break of gauge. On the other hand, the South African railways are built to 3 feet 6 inches; and if the so-called Cape-to-Cairo railway is ever completed, there will be one gauge from Upper Egypt to Cape Town.

Sleepers.

For sleepers (called cross-ties or ties in the United States) wood is the material still generally used. Metal is employed for the purpose in a few countries where timber is scarce, or liable to destruction by white ants, and, also somewhat experimentally, on a considerable mileage on the continent of Europe; but its use there is not increasing, and in the United States it is exceedingly limited. In England, Germany, and France at least 90 per cent. of the wooden sleepers are treated before they are laid, to preserve them from decay, and the same practice is followed to some extent in other European countries. A great number of preservative processes have been tried (many of them patented), but the one now most largely used is that known as "creosoting." Dead oil of coal tar is forced into the wood under pressure, or sucked in under vacuum, both the timber and the oil being heated. In the United States only a very small percentage of the cross-ties are treated in any way beyond seasoning in the open air, timber being still too cheap in nearly all parts of that country to justify preservative treatment—at least so the officials of the railways think. A few lines, however, which have a long mileage in timberless regions do treat their sleepers. Probably the large majority of railway engineers in nearly all countries believe that timber sleepers, preserved in some way, and protected from direct wear by plates or chairs under the rail, will be standard practice for many years. Steel is the only material that can be substituted for wood in the present stage of invention, and generally it is still too costly for this use.

Rails.

One of the most important events in the whole history of the railway was the substitution of steel for iron rails. That made possible the wheel weights and the speeds of to-day, and diminished the cost of maintenance of track to such a point as made possible the rates of to-day. The continued improvement of the steel rail in stiffness of section and in toughness and hardness of material is an element of progressive economy almost as important as the substitution of steel for iron. The weight of rail has increased, particularly in the United States, and in Great Britain rails weighing 95 and 100 lb per yard are now largely laid on main lines. Harder steel is also employed. The important element in controlling this quality is carbon, and in their notions of desirable carbon contents the rail makers and users of Great Britain differ from those of the United States. Generally speaking the rail steel of the United States is higher in carbon, hence harder, than that made and used in England. In the United States the best and most widely accepted practice is from 0·43 per cent. of carbon as the minimum limit for light rails up to 0·70 per cent. for the top limit for heavy rails. Nevertheless, it is true that even there some rail-makers and railways still specify the minimum carbon as low as 0·35 per cent. In Great Britain the limits of carbon adopted range from 0·25 up to 0·50 per cent., but in the greater number of cases 0·4 is specified as the lower limit. It will be seen, therefore, that there is practical agreement in the two countries as to the minimum of carbon, but a wide difference as to the maximum. The tendency on the Continent is towards harder steel than prevails in England. In recent years there has been a real advance in the art of making rails. This has not consisted so much in the acquisition of new knowledge as in the spread of knowledge from a few men to many. It has come to be widely known that the treatment of the steel from the time of melting to the last passage through the rolls is quite as important as the chemistry of the stock. Especially has it become known to many, as it has long been known to a few, that the last work on steel must be done at a comparatively low temperature if the product is to be fine-grained, homogeneous, and tough. The spread of this knowledge has already affected the outline of the cross-section of the rail, in the United States at least, and it will soon begin to affect rolling-mill practice.

To understand how a more correct knowledge of mill treatment has affected the rail section we must look at the typical sections used. In the United Kingdom the

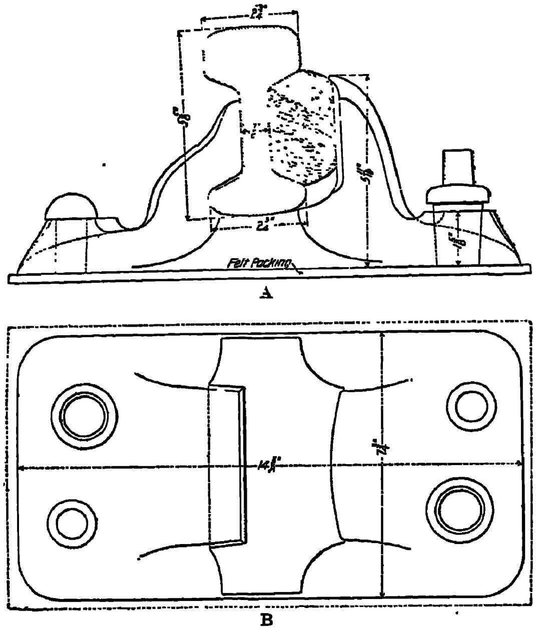

FIG. 1.—A, section of English bull-head rail, 90 lb to the yard, showing also chair and fastenings; B, plan of chair.

standard rail section is the bull-head, which is shown in Figs. 1 and 2. This is used also to a comparatively small extent in France and in India. The rail section much more generally used, always in the United States and nearly always on the continent of Europe, is frequently called the Vignoles section, or in the United States the T rail (Figs. 3 and 4). It is also often spoken of as a flange rail. An inspection of the figures will show that in the bull-head rail the weight of metal in the top and bottom members is not very different, and that the neck (or web) is comparatively thick. Similarly, it will be seen that

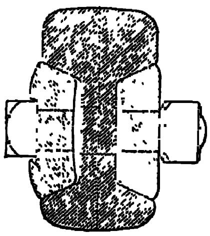

FIG. 2.—English rail and rail joint.

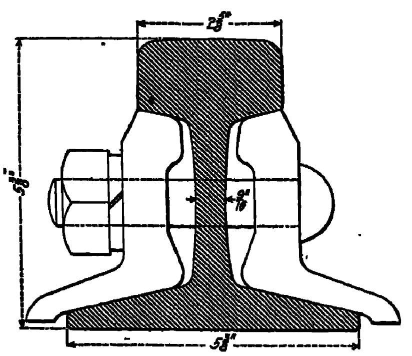

FIG. 3.—American rail, 90 lb to the yard, showing rail joint.

in the Vignoles section the flange or foot is broad and thin, and that there is considerably less metal in the flange than in the head. It will be understood, then, that one part of the bull-head rail cools about as fast as another, but that the flange of the Vignoles rail cools much faster than the head. The result of this is that the finishing passes must be made while the head is at a temperature too high to give good results—otherwise, the flange would be too cool to be rolled. This fact resulted in the development in the United States of what are there called balanced sections—that is, sections in which the metal is divided approximately equally between the head and the flange—and, furthermore, the head is made comparatively broad and thin. The final development of this section was reached in 1893, when the American Society of Civil Engineers recommended a set of standard sections, one

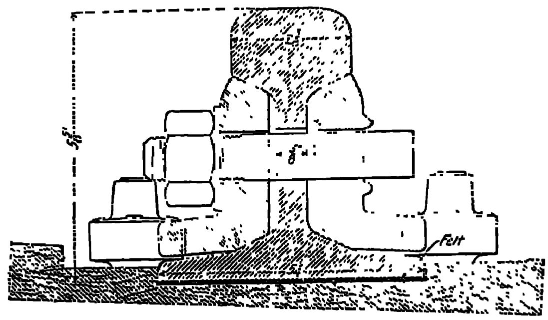

FIG. 4.—French rail, 90½ lb to the yard, showing also rail joint and seat in the sleeper.

of which is seen in Fig. 3. By comparing this with the French rail (Fig. 4) the reader may see the difference in the distribution of the metal. These balanced sections are now standard on many railways, their use is increasing, and, so far as we can now foresee, they are destined to prevail, except that the flange will probably be made thicker. The bull-head section is a better section to roll, but track made with it is more costly, and changes are less convenient; it now seems likely that its use will be continued indefinitely in the British Islands, but that it will not supersede the flange rail elsewhere. The spread of knowledge of the mill treatment of rails is likely to bring about still another change in mill practice, namely, such an arrangement of rolls as will retard the progress of the rails just before they reach the finishing rolls, and permit their temperature to fall, thus making the finishing passes cooler than is now ordinary practice. This will probably be brought about by introducing a table over which the rails will move slowly but continuously, fed up to the finishing rolls at a uniform rate, but having time to cool while on this table. Obviously rail-makers will not permit any change in practice to be made which would diminish the speed and regularity of the output, and it is not for the interest of anybody that such a thing should be done. The plan now developing, as briefly outlined above, will not lessen the speed or quantity of output; it will merely require additional machinery and additional room.

Joints and fastenings.

A few types of rail joints and fastenings are shown in the figures, and little need be added to what the cuts tell. In the United States the joint shown is well-nigh universal. It consists of two symmetrical angle bars, and the variations are in length (from 20 inches to 48 inches), in weight, and in the number of bolts, which may be four or six for each joint. The best length of joint is still much debated. Other joints than the type shown (almost invariably patented) are used, and some of them largely, but far the greater number are of the angle splice type seen in Fig. 3.

Rails in the United States are usually laid directly on the sleepers and spiked with hook-headed spikes driven with a maul. The whole arrangement is simple, and lends itself admirably to fast track-laying, and to repairs and changes of line. Further, it is cheap in first cost, but obviously it is not so durable or so stable as the British and Continental methods. Of late years tie plates have come into considerable use, and their use is increasing. These plates, in the United States, are always made of rolled steel and punched with rectangular holes, through

which the spikes are driven. All the accepted forms now have two or more flanges on the bottom of the plate, running lengthwise of the plate and crosswise of the rail; these are necessary to give the plate proper stiffness, and further, as they are driven into the tie by the weight of passing traffic, they help to fix the plate securely in its place. The plates are laid between the rail and the cross tie and serve two principal purposes: they diminish the wear of the tie under the rail, and they help to support the spike and so to keep the gauge. In Great Britain the simple fish-plate joint, as shown in Fig. 2, is used, often provided with flanges depending vertically below the bottom of the rail, to give additional stiffness to the joint. The rail is laid in a cast-iron chair and held there by a key driven in alongside the rail; this key, which is usually of oak, though sometimes of metal, is now generally placed outside the rails, though the inside position is still to be seen occasionally. The chair is held to the sleeper by screwed spikes and by round drift bolts, which are entered in holes already bored in the sleeper. On some railways, *e.g.*, the Great Western and the Taff Vale, fang bolts are employed. With what has been said of practice in the United States and Great Britain, the figures of Continental joints and fastenings will explain themselves. Wherever the bull-head rail is used, it must be laid in chairs; but the usual Continental practice is to use the Vignoles rail, with plates or strips of felt beneath it, all very carefully fastened to sleepers by screwed spikes. The diagram (Fig. 4) of the French rail and joint shows also the rail seat in the sleeper. The practice of notching the sleeper in this way, and giving the rail a slight cant inwards, is very common on the Continent. The same result is reached in England by canting the rail in its chair. This is never done in the United States, where the rails stand upright; and little pains are taken to prepare seats for them on the ties, on which they soon seat themselves. On the Great Western Railway the practice is to prepare a serrated surface on the sleeper for the chair, which is forced into its seat by hydraulic pressure. On the London and North-Western a strip of felt is interposed between the chair and the sleeper. There is a tendency in Great Britain to increase the weight and bearing-surface of the chairs, also the number of sleepers per mile.

Permanent way.

A section of road-bed typical in the United States is shown in Fig. 5. In Great Britain and the Continent the sleepers are frequently covered with the ballast up to the level of the top of the rail—a practice which adds to stability, but makes inspection and maintenance somewhat more difficult. In general, the reader will be struck by one broad distinction between American and European practice in railway track, namely, the greater expenditure in Europe to get security and permanence. Space does not permit analysis of the causes of this interesting phase of the subject; but underneath it lie the facts that in the United States money and labour were dear, vast and thinly-peopled areas had to be crossed and developed, and the citizen was left to work out his enterprises with the least possible official control. With the gradual equalizing of conditions in the civilized countries of the earth there is a slow but steady movement in the direction of uniformity in railway construction. Various proposals, however, have been brought forward from time to time for constructing railways on principles radically different from those generally followed. In the Lartigue system, for instance, the train is straddled over a single central rail, elevated a suitable distance above the ground. Several small lines have been constructed on this plan, including one, worked by steam, between Ballybunnion and Listowel in Ireland; and in 1901 a Bill was passed by Parliament authorizing a more ambitious railway on the same principle, from designs by Mr F. C. Behr, to connect Liverpool and Manchester. The motive-power is to be electricity, and it is proposed to run frequent trains without a stop between the two places at a speed exceeding 100 miles an hour. In the Langen monorail the car is hung from a single overhead rail; a line on this system is worked between Barmen and Elberfeld, a distance of about 9 miles, the cars for a part of the way being suspended over the river Wupper.

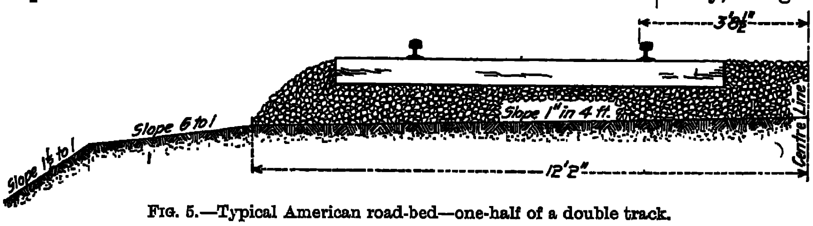

FIG. 5.—Typical American road-bed—one-half of a double track.

The important subjects of tunnels and bridges as related to railway construction are not taken up here, because they are treated in the special articles on those subjects.

(H. G. P.)

SIGNALLING.

In railway phraseology the term "signal" is applied to a variety of hand motions and indications by lamps and other symbols, as well as to fixed signals; but only the last-named class—discs and semaphores, with lights, permanently fixed (on posts) at the side of the track—will be considered here. These may be divided into (1) interlocking signals, used at junctions and yards, and (2) block signals, for maintaining an interval of space between trains following one another. In either class the function of a signal is to inform the engine-driver whether or not he may proceed beyond the signal, or on what conditions he may proceed, and it is essential to give him the information some seconds before it need be acted upon.

Interlocking.

So early as 1846 it became a common practice in England to concentrate the levers for working the points and signals of a station in one or more cabins, and the necessity of interlocking soon became evident to prevent simultaneous signals being given over conflicting routes, or for a route not yet prepared to receive the train. In large terminals concentration and interlocking are essential to rapid movement of trains and economical use of ground. The form of signal now approved practically everywhere is the semaphore (Fig. 7), an arm or blade about 5 feet long extending out horizontally, at right angles to the line of the track, from the top of a post (wood or iron) 15 to 30 feet high, and sometimes higher. This arm, turning on a spindle, is pulled down ("off") to indicate that a train may pass it. The horizontal (or "on") position indicates "stop." A lamp is fixed to the side of the post about on a level with the blade, and by the movement of the blade is made to show at night red for "stop" and green for go-ahead or "all clear." The earlier practice, white for "all clear," still prevails largely in America. The signal is worked from a cabin by rods or wires.

In the early days of railway signalling three positions of the semaphore arm were recognized:—(1) Horizontal, or at right angles to the post, denoting danger; (2) at a downward angle of 45 degrees, denoting caution; (3) hanging vertically downwards or parallel to the post, denoting all right. Corresponding to the position of the arm, three different lights were employed at night —red for danger, green for caution, and white for all right. But of late years, in consequence of the introduction of block-working, British railways make use of only two positions of the arm and two lights—the arm at right angles to the post and a red light,

both signifying danger or stop; and the arm at about 60 degrees and a green light, both meaning all right or proceed. Some companies, while adopting the two positions of the arm or semaphore, still adhere to the use of the three lights—red, green, and white. But the more modern practice of using only red and green lights for signals is far preferable. The reason is obvious. There are many lights and lamps on the platforms, in signal-boxes, and in the streets and houses adjacent to a railway; and if white lights were recognized as signals, a driver might mistake a light of this nature as a signal to proceed: in fact, accidents have been caused in this manner. It is therefore better to abolish the use of white lights for signalling purposes. A white light is not to be regarded as a danger signal, as is sometimes erroneously stated, but rather as no signal at all; and as there is a well-known rule to the effect that "the absence of a signal at a place where a signal is ordinarily shown must be treated as a danger signal," it follows that a white light, when seen at a place where a red or green light ought to be visible, is to be treated as a danger signal, not because a white light *per se* means danger, but because in such a case it denotes the absence of the proper signal. Some companies have adopted a purple light as a "danger" signal for shunting purposes in sidings and yards; but this practice is not to be commended, since red should be the universal danger signal. On the other hand, a few companies have adopted the purple light as an "all-right" signal for shunting purposes, to which there is no objection.

Distant signals are used to make it unnecessary for an engine-driver to slacken his speed in case the stop (*home*) signal is obscured by fog or smoke, or is beyond a curve, or for any reason is not visible sufficiently far away. Encountering the distant signal at a point 400 to 800 yards before reaching the home signal, he is informed by its position that he may expect to find the latter in the same position. The arm of a distant signal usually has a fish-tail end. In America its night colour-indication is made different from that of the home signal. Thus, where white is used to indicate all clear (in both home and distant) the distant arm, when horizontal, shows a green light; where green is the all-clear colour a horizontal distant shows either a yellow light or (on one road) a red and a green light side by side. Two lights for a single arm, giving their indication by position as well as colour, have been used to a limited extent for both home and distant signals. *Dwarf signals* are used for very slow movements, such as those to or from a siding. In cases where room must be economized, signals are usually placed on narrow overhead bridges or "gantries" spanning a number of tracks.

Fig. 6 shows a typical arrangement of interlocked signals, the principle being the same whether a yard has

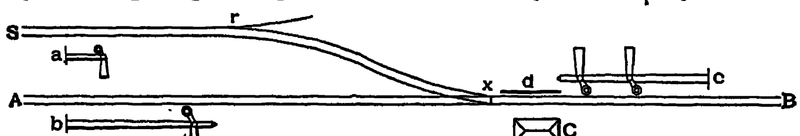

FIG. 6.—Interlocked signals (American practice, signals at right of track, and arms at right of post).

one set of points or a hundred. The signals (at *a*, *b*, and *c*) are of the semaphore pattern (Fig. 7). For the four signals and one pair of points there are, in the second storey of the cabin C, five levers. Each signal arm stands normally in the horizontal position, indicating stop. To permit a train to pass from A to B the signalman moves the arm of signal *b* to an inclined position (60 degrees to 75 degrees downwards); and the interlocking of the levers prevents this movement unless it can safely be made. If *a* has been changed to permit a movement from S to B, or if the points *x* have been set for such a movement, or if either signal on post *c* has been lowered, the lever for *b* is immovable. In like manner, to incline the arm of signal *a* for a movement from S to B it is first necessary to have the points set for track S, and to have the levers of all the other signals in the normal (stop) position. A sixth lever, suitably interlocked, works a lock bar, which engages with the head rod of the points; it is connected to the lock through bar *d* (called in America the detector bar). This bar, about 45 feet long, lying alongside of and close to the rail, must move upwards when the points lock is being moved either to lock or to unlock; and as it is held down by the wheels of any car or engine standing or moving over it, the signalman is prevented from inadvertently changing the points when a train is passing. At *r* is a throw-off or derailing switch ("catch-points"). When *x* is set for the passage of trains on the main line, *r*, connected to the same lever, is open; so that if a car, left on the side track unattended, should be accidentally moved from its position, it could not run foul of the main track. The dwarf signal *a* being for slow movements, has a blade about 1 foot long, and the post is about 4 feet high; the lower arm on post *c* being for slow movements, is also frequently made shorter than the upper one. Where more than two full-sized arms are used on a post, the custom in America is to have the upper arm indicate for the track at the extreme right, and the others in the order in which the tracks lie; in Great Britain the opposite rule prevails, the upper arm indicating for the extreme left.

All the switches and locks are connected with the signal cabin by iron rods (channel-iron or gas-pipe) supported (usually near the ground and often covered by boxing) on small grooved wheels set at suitable distances apart. The foundations of these supports are of wood, cast iron, or concrete. Concrete foundations are comparatively recent, but are cheap and durable. For signals (but not for points) wire connexions are universal in England, and are usual in America, being cheaper than rods. In changing the direction of a line of rodding (pipe) a bell-crank is used, but with a wire a piece of chain is inserted and run round a grooved pulley. Wire connexions are shown at *a* and *b*, Fig. 7, the main or "front" wire being attached at *a*.

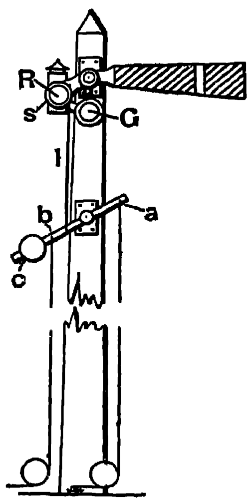

FIG. 7.—Semaphore signal. R, red glass; G, green glass.

By this the signalman moves the arm down to the inclined or go-ahead position, to do which he has to lift the counter-weight *c*. If the wire should break, the counter-weight would restore the arm to the horizontal (stop) position, and thus prevent the unauthorized passage of a train; and in case of failure of the rod l, the iron spectacle *s* would act as a safety counter-weight. The back-wire *b* is added to ensure quick movement of the arm, but is not common in England. Long lines of rigid connexions are "compensated" for expansion and contraction due to changes in temperature by the introduction of bell-cranks or rocker-arms. With wire connexions compensation is difficult, and many plans have been tried. The most satisfactory devices are those in which the connexion, in the cabin, between the wire and the lever is broken when the signal is in the horizontal position. The wire is kept taut by a weight or spring, and at each new movement the lever (if the wire has lengthened or shortened) grips it at a new place.

The function of the interlocking machine is to prevent the simultaneous display of conflicting signals, or the display of a signal over points that are not set accordingly. The most common forms of interlocking have the locking bars arranged in a horizontal plane; but for ease of description we may take one having them arranged vertically,

the principle being the same. The diagram (Fig. 8) shows a section with a side view of one lever. A machine consists of as many levers, placed side by side, as there are points and signals to be moved, though in some cases two pairs of points are moved simultaneously by a single lever, and two or more separate arms on the same post may be so arranged that either one of them will be moved by the same lever, the position of the point connexions being made to govern the selection of the arm to be moved. A switch rod would be connected to this lever at H; the lever K is for use where a signal is connected by two wires, as before described. The lever is held in each of its two positions by the catch rod V, which engages with notches in the segment B. When the signalman, preparatory to lowering a signal, grasps the lever at its upper end, he moves this rod upwards, and in so doing actuates the interlocking, through the tappet N, attached at T. Lifting the tappet locks all levers which need to be locked to make it safe to move this one. In pulling over the lever the rocker R is also pulled; but the slot in it is radial to the centre on which the lever turns, so that during the stroke N remains motionless. On the completion of the stroke and the dropping of V, N is raised still farther, and this unlocks such levers as should be unlocked after this lever is pulled ("cleared" or "reversed"). It will be seen that whenever the tappet N of any lever is locked in the position shown in the figure, it is impossible to raise V, and therefore impossible to move the lever.

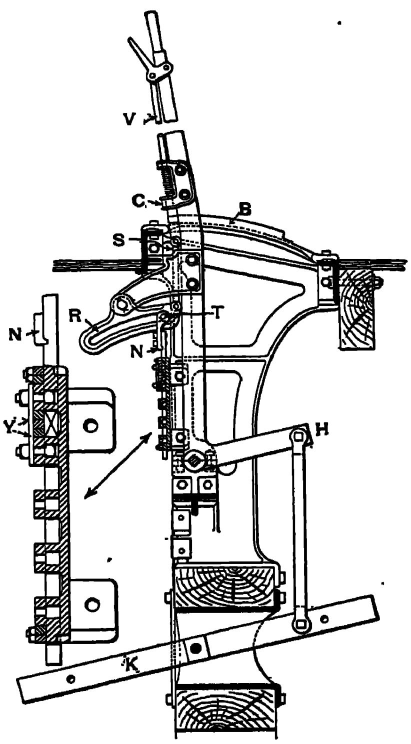

FIG. 8.—Signal lever, with mechanical interlocking.

The action of tappet N may be understood by reference to Fig. 9. A tappet, say 3, slides vertically in a planed recess in the locking plate, being held in place by strips G and K. Transverse grooves N, O, P, carry dogs, such as J. Two dogs may be connected together by bars, R. The dogs are held in place by straps Y (Fig. 8). Locking is effected by sliding the dogs horizontally; for example, dog J has been pushed into the notch in tappet 1, holding it in the normal position. If tappet 2 were raised, its notch would come opposite dog J; and then the lifting of 1 would lock 2 by pushing J to the left. By means of horizontal rod R, the lifting of 1 also locks 4. If 4 were already up, it would be impossible to lift 1.

"*Power interlocking*" is the term used to describe switch and signal machines worked by compressed air, or electric or hydraulic power. The use of power makes it possible to move points at a distance from the cabin. The most widely used apparatus is the electro-pneumatic, which has been installed at over seventy plants in America and to some extent in other countries. One of these, at the South Station, Boston, is probably the most elaborate interlocking plant in the world. In this system points and signals are moved by compressed air at 70 ℔ per square inch, a cylinder with piston being fixed at each signal or switch. From a compressor near the cabin air is conveyed in iron pipes buried in the ground. The valves admitting air to a cylinder are controlled by electromagnets, the wires of which are laid from the cabin underground. Each switch or signal, on completing a movement, sends an electric impulse to the cabin, and the interlocking is controlled by this "return." In the machine the "levers" are very small and light, their essential function being to open and close electric circuits. This is performed through the medium of a long shaft, placed horizontally with its end towards the operator, which is revolved on its axis through 60 degrees of a circle. This shaft actuates the interlocking, which is in principle the same as that already described; and it opens and closes the electric circuits, governing the admission of air to cylinders, by means of simple metal contact strips rubbing on sections of its surface. The high-

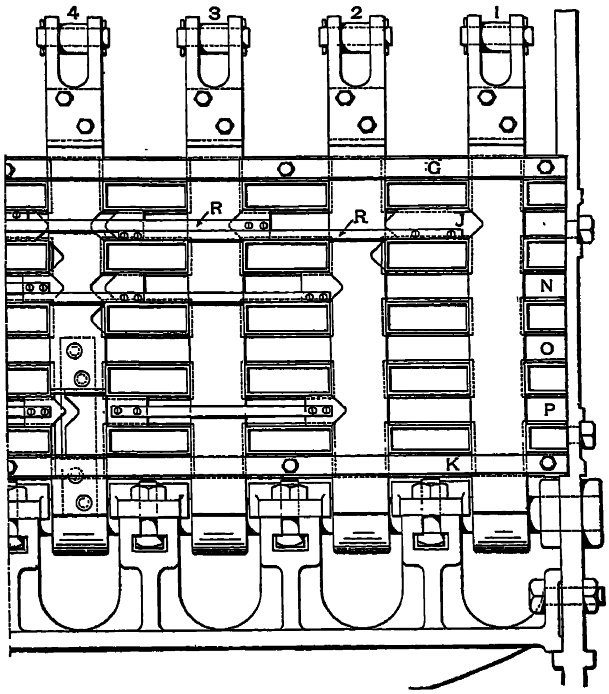

FIG. 9.—Interlocking frame.

pressure machine has been used with hydraulic power instead of pneumatic, and with electrical interlocking instead of mechanical.

Interlocking apparatus worked by compressed air at low pressure (15 ℔ per square inch), and with no electrical features, is in use on some lines in America and has been introduced into England. In place of an electromagnet for admitting compressed air to the cylinders, a rubber diaphragm 8 inches in diameter is used. This is lifted by air at 7 ℔ pressure, this pressure being conveyed from a cabin, 500 feet or more, in one or two seconds. As in the electro-pneumatic machine, the lever of a switch cannot complete its stroke until the switch has actually moved home and conveyed a "return indication" to the cabin. Pneumatic apparatus of other designs is in use to a limited extent.

Pneumatic interlockings are costly to instal, and, depending on an unfailing source of power, have not been much used at isolated places, except on railways where an air-pipe is installed for block signals; but at large yards the pneumatic machines have been made a means of

economy, because one attendant can manage as many levers as can two or three in a manual power machine. Moreover, a single lever will work two or more switches, locks, &c., simultaneously, where desirable. The absence of outdoor connexions above ground is also an advantage.

Since about 1900 electric power has come into use for working both points and signals; although, as mentioned below, motors have been used since about 1897 for isolated automatic signals. At interlocking a motor, with gearing and cranks, is fixed to the sleepers at each pair of points. The power is conveyed from the cabin by underground wires, the locking is of common mechanical types, and, in general, the system is similar to pneumatic systems except in the source of power. By using accumulators, charged by dynamos run by gasoline engines, or by a travelling power-car, the cost of power is reduced to a very low figure, so that power-interlocking becomes economical at small as well as large stations. Electric interlocking is extensively used at Crewe, on the London and North-Western, and at Chicago, Illinois.

Block signalling.

The essence of block signalling is a simple regulation forbidding a train to start from station A until the last preceding train has passed station B. As the introduction of the telegraph was almost or quite contemporaneous with the advent of the railway, the possibility of a block system was early recognized; but its introduction was retarded by the great cost of employing attendants at every block station. But as traffic increased, the time-interval system, dependent, in the case of irregularities, on the efficiency of a flagman, proved inadequate; and in the United Kingdom the block system is now practically universal, while in America it is in use on many thousand miles of line. The Continent is far behind Great Britain.

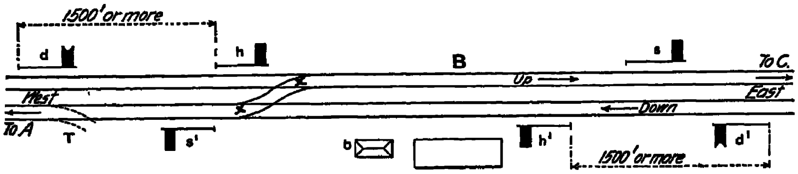

FIG. 10.—Block signals. (English practice, trains run on left-hand track, signals at left of track, arms on left of post.)

The manual "block" system in use at the present day in no way differs from that devised by Cooke in 1842, except so far as the details and designs of the telegraphic instruments are concerned. Cooke used a single-needle instrument giving two indications—the needle to the left signifying "line clear," to the right, "line blocked"; the instrument being also available for speaking purposes. The instruments employed in Great Britain consist of two dials—one for the up line and one for the down—and a bell. They may be divided into two main classes, those requiring one wire, and those requiring three wires for each double line of rails. The dials of the one-wire instruments give only two indications, namely, "line clear" and "train on line" or "line blocked," the latter being the normal indication, even when there is no train in the section. The three-wire instrument has the advantage of giving three indications on the dial, namely, "line clear," "line closed," and "train on line," the normal indication being "line closed." The one-wire instrument differs from the three-wire in that the indicator is moved over to the different positions by a momentary current, and is then held there by induced magnetism, the wire being then free for any succeeding signals. In the three-wire apparatus there is a separate wire, with an instrument at each end for the up line; the same for the down line; and a wire for the bell, which is common to both lines. When no current is flowing, the indicator is vertical, meaning "line blocked or closed." When a current is sent along one of the wires, the deflections to the right or left, according to the polarity of the current, mean "line clear" or "train on line" respectively. Some dial instruments are made with needles, some with small discs, some with miniature semaphores to give the necessary indications, but the effect is the same. The block instruments and bells should not, as a rule, be used for speaking purposes; but on a few subsidiary railways, block working is effected by means of ordinary single-needle telegraphic instruments, or by telephone, the drawback to such an arrangement being that the signalman has no indication before him to remind him of the condition of the line.

Fig. 10 shows the signals at a typical English station, which may be called B. Notice having been received over the block telegraph that a train is coming from A (on the up track), the signalman in the cabin, *b*, lowers the home signal *h*; and (if the block section from B to C is clear of trains) he lowers the starting signal, *s*, also. The function of a distant signal *d* has already been described; it cannot be lowered unless *h* has been lowered. The relation of the signals to the "crossover road" *xx* is the same in principle as is shown in Fig. 6. Dwarf signals are omitted from the sketch. Where the sections are very short, the starting signal of one section is often placed on the same post as the distant signal of the next. Thus, supposing B and C to be very close to each other, B's starting signal would be on the same post as C's distant signal, the latter being below the former, and the two would be so interconnected by "slotting" apparatus that C could not lower his distant signal unless B's starting signal was "off," while B by the act of raising his starting arm would necessarily throw C's distant arm to "danger." In America many block stations have only the home signal, even at stations where there are points and sidings, and on double-track lines the block telegraphing for both is done on a single Morse circuit. In the United Kingdom the practice is to have separate apparatus and separate wires for each track.

Lock-and-block.

In the simple block system it is clearly possible for a signalman, through carelessness, forgetfulness, or other cause, so to lower his signals as to admit a second train into the block section before the first has left it, and that without the driver of either train being aware of the fact. To eliminate as far as possible the chance of such an occurrence, which is directly opposed to the essence of the block system and may obviously lead to a collision, the locking of the mechanical signals with the electrical block instruments was introduced in England by Mr W. R. Sykes about 1876, the apparatus being so arranged that a signalman at one end of a section is physically unable to lower his signals to let a train enter that section until they have been released electrically from the cabin at the other end. The starting signal at a block section A cannot be lowered until the signalman at the next station B, by means of an electric circuit, unlocks the lever in connexion with it. In so doing he breaks the unlocking circuit at his own station, and this break is restored only on the arrival of the train for which the unlocking was performed, the wheels of the train acting through a lever or by a short rail circuit. Valuable improvements have been made in this machine by Patenall, Coleman, and others, and these are in use in America. The passage of a train is also made to set a signal at "stop" automatically, by disconnecting the rod between the signal and its lever. The connexion cannot be restored by the signalman; it must be done by an electromagnet brought into action by the train as it passes the next block station.

"Lock-and-block" has been used to a limited extent on a good many lines in England and a half-dozen in America, but of extensive installations there were in 1901 only four: two in America—the New York, New Haven, and Hartford, 229 miles, and the New York Central and Hudson River, 457 miles, and two in England—the South-Eastern and Chatham and the London and South-Western.

In "permissive blocking," an objectionable practice

which is occasionally resorted to on many lines, especially in America, a second train is permitted to enter a section before the preceding one has cleared it, the engineman being required so to control his speed that if the preceding train be unexpectedly stopped he can himself stop before colliding with it. With this practice "lock-and-block" would be useless.

The block system is used on single as well as on double lines. In the United Kingdom and in Australia the means for preventing collisions between trains running towards each other is the "staff system."

Staff system.

The staff, suitably inscribed, is delivered to the engine-driver at station A, and constitutes his authority to occupy the main track between that station and station B. On reaching B he surrenders the staff, and receives another one which gives him the right to the road between B and C. If there are two or more trains to be moved, all except the last one receive tickets, which belong to that particular staff. The staff system requires no telegraph; but to obviate the inconvenience of sometimes finding the staff at the wrong end of the road, electric staff apparatus has been devised. Staffs (or tablets) in any desired number are kept at each of the two stations, and are locked in a cabinet automatically controlled, through electromagnets, by apparatus in the cabinet at the other station; and a staff (or tablet) being taken out at one station, a second one cannot be taken out at either station until this first one is returned to the magazine at one station or the other. Thus we have a complete block system. By simple "catching apparatus" on the engine, staffs or tablets may be delivered to trains moving at a good speed. The electric staff is used in Great Britain, in Australia, and on half a dozen roads in America.

In America automatic rail-circuit block signals are extensively used, and the Pennsylvania Railroad has substituted them for non-automatic on its main line.

Automatic signals.

They have been introduced in England and France (1901), but only on a very few lines. The apparatus is costly, and so is inspection; but at block stations where there are no points the wages of a signalman are saved. The block sections are made shorter, usually less than a mile long. There are three styles in general use, the Hall (introduced in 1871), the Union clock-work (1880), and the Westinghouse electro-pneumatic (1884). Within the past few years all manufacturers have made signals worked by individual electric motors, and these have been introduced extensively in America. Energy is derived from a non-freezing battery at each post, or from accumulators fed by wires from dynamos situated, say, every 10 miles along the line. Another recent device is the gas-motor signal. A tank of carbonic acid gas, at the foot of the post, furnishes power for several thousand movements. Line-wire circuits have been about abandoned everywhere, and the rail circuit is universal.

FIG. 11.—Automatic electric block signal, with rail circuit.

Fig. 11 shows the arrangement of a rail circuit. The disc is fixed to a vertical spindle (Fig. 12), and the clock-work revolves the spindle on its axis, one-quarter turn at each operation. The current from the main battery *b* flows through the rails of one side of the track to the signal *s*, through an electromagnet which controls the clock-work, and back to the battery through the other rail. The presence on any part of this block section of a train, or any vehicle with metal wheels connected by metal axles, short-circuits the current from the battery, so that the relay (placed vertically) drops its armature. This releases the clock-work and causes the signal disc to turn so as to indicate "stop." On the restoration of the current the signal makes another quarter turn and then shows only its edge to the approaching train, indicating "all clear." At each rail joint a wire is used to ensure electrical continuity, and at the ends of each block section there are insulating joints. The current for a rail circuit must be of low tension because of the imperfect insulation. As a rule the ballast must not be allowed to touch the rails, and it must be free from iron or other conducting material. Block sections more than about 1 mile long are usually divided into two or more circuits, connected together by relays. At points the rail circuit is run through a circuit breaker, so that the "opening" of the points will set the signal for that section. The circuit is also run through the rails of the side track as far as it fouls the main track. An indicator at each switch gives audible or visual warning of the approach of a train

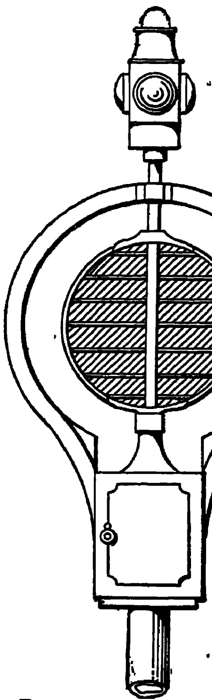

FIG. 12.—Signal moved by clock-work (Union).

The enclosed disc signal, commonly called a "banjo" (Fig. 13), is a circular box about 4 feet in diameter, with a glass-covered opening, behind which a red disc is shown to indicate stop. The disc, very light, made of cloth stretched over a wire, or of aluminium, is supported on a spindle, which is delicately balanced on a pivot so that the closing of an electromagnet lifts the disc away from the window and thus indicates "all clear." On the withdrawal or failure of the current the disc falls by gravity to the "stop" position. A local battery is used, with a relay, the rail circuit not being strong enough to lift the disc.

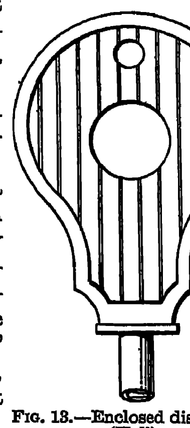

FIG. 13.—Enclosed disc signal (Hall).

In the electro-pneumatic system a full-size semaphore is used. Compressed air, from pumps situated at intervals of 10 to 20 miles, is conveyed along the line in an iron pipe, and is supplied to a cylinder at each signal, exactly as in pneumatic interlocking, before described. The rail circuit, when complete, maintains pressure in a cylinder, holding the signal "off." On the entrance of a train or the failure of the current, the air is liberated and the signal arm is carried by gravity to the "stop" position.

Automatic signals are sometimes made to stand normally (when no train is in the section) in the "stop" position. The local circuit is connected with the rail circuit so that it is closed only when a train is approaching within, say, one mile. With the rail circuit, distant signals are controlled, without a line wire, by means of a polarized relay. Each signal, when cleared, changes the polarity of the rail circuit for the next section in its rear, and this, by the polarized relay, closes the local circuit of the distant signal, without affecting the home signal for that section.

Automatic signals are used in America on a few single lines. The signal at A for the line AB is arranged as before described; and the signal at B, for movements in the opposite direction, is worked by means of a line wire from A, strung on poles. When a section is occupied, signals are set *two* sections away, so as to provide against the simultaneous entry of two trains.

The length of railway in the United States equipped with automatic block signals was in 1902 about 4000 miles.

Fog-signalling. One of the chief causes of anxiety and difficulty in the working of railway traffic is fog, which practically blots out the whole system of visible signals, so that while the block telegraph remains, the means of communicating the necessary instructions to the driver are no longer effective. Delay and confusion immediately arise; and in order to secure safety, speed has to be lessened, trains have to be reduced in number, and a system of "fog-signalling" introduced. In England, especially around London, elaborate arrangements have to be made. "Fog-signalling" consists in the employment of audible signals, or detonators, to convey to drivers the information ordinarily imparted by the visible or semaphore signals. As soon as possible after a fog comes on, a man is stationed at the foot of each distant signal, and generally of each home signal also, who by means of detonators, red and green flags, and a hand-lamp conveys information to the driver of every train as to the position of the semaphore arm. A detonator is a small flat metal case about 2 inches in diameter and ½ inch deep, furnished with two leaden ears or clips which can be easily bent down to grip the head of the rail. The case contains some detonating composition, which readily explodes with a loud report when a wheel passes over it. As soon as a signal arm is raised to "danger," the fogman places upon one of the rails of the track to which the signal applies two detonators, or in the case of a new and improved class of detonator which contains two separate charges in one case, one detonator, and at the same time exhibits a red flag or light to the driver of an approaching train. The engine of a train passing over the detonators explodes them, the noise so made being sufficient to apprise the driver that the signal, though invisible to him, is at danger, and he then should act in the same way as if he had seen the signal. If, however, the signal arm should be lowered to the "all-right" position before a train reaches it, the fogman should immediately remove the detonators and exhibit a green flag or lamp, replacing the detonators as soon as the signal is again raised to danger. As a rule the fogmen are drawn from the ranks of the permanent-way men, who otherwise would be idle. But if, as sometimes happens, a fog continues for several days, great difficulty is experienced in obtaining sufficient men to carry on this important duty without undue prolongation of their hours of work. When this happens, signalmen, shunters, porters, yardsmen, and even clerks may have to be called on to take a turn at "fogging." Some companies have adopted mechanical appliances, whereby a man can place a detonator upon a line of rails or remove it while standing at a distance away from the track, thus enabling him to attend to more than one line without danger to himself. The cost of detonators often amounts to a considerable sum; and an apparatus called an *economizer* has been introduced, whereby the explosion of one detonator removes the second from the rails before the wheels reach it. As it is only necessary for one detonator to explode, the object of placing two on the rails being merely to guard against a miss-fire, considerable saving can thus be effected. Many attempts have been made to design a mechanical apparatus for conveying to a driver the requisite information as to the state of the signals during a fog, and for enabling the fogmen to be dispensed with. Such inventions usually consist of two parts, namely, (1) an inclined plane, or block, or trigger, placed on the permanent way alongside the track or between the rails, and working in connexion with the arm of the signal; and (2) a lever or rod connected with the steam-whistle, or an electric bell or indicator on the foot-plate, and depending from the underside of the engine in such a position as to come in contact with the apparatus on the ground, when the latter is raised above the level of the rails. Most of the proposed systems only give an indication when the signal is at danger, and are silent when the signal is off. This is contrary to good practice, which requires that a driver should receive a positive indication both when the signal is "off" as well as when it is "on." If this is not done, a driver may, if the signal is "off" and if the fog is thick, be unaware that he has passed the signal, and not know what part of the line he has reached. The absence of a signal at a place where a signal is usually exhibited should invariably be taken to mean danger. Fog signals that depend on the explosion of detonators or cartridges have the drawback that they require recharging after a certain number of explosions, varying with the nature and size of the machine. Even when a satisfactory form of appliance has been discovered, the manner of using it is by no means simple. It is clearly no use placing such an apparatus immediately alongside a stop signal, as the driver would receive the intimation too late for him to be able to stop at the required spot. To place devices of this description at or near every stop signal in a large station or busy junction would involve a multiplication of wires or rods which is undesirable. Every such apparatus should certainly be capable of giving an "all-right" signal as well as a "danger" signal. It requires very careful maintenance, and should be in regular daily use to ensure its efficiency.

Development of signalling. The fundamental principles of railway signalling are simple, but the development of the science has called for much study and a large money outlay. On every railway of any consequence the problems of safety, economy, and convenience are involved, one with another, and cannot be perfectly solved. Not for twenty years after block signalling was acknowledged to be desirable did the railways of Great Britain deem themselves able to afford the money to make its use universal. Even so fundamental a duty as that of guarding the safety of life and limb is a relative one, when we have to consider whether a certain expenditure is justifiable for a given safety device. Having good discipline and foregoing the advantages of high speed, many a manager has successfully deferred the introduction of signals; others, having to meet severe competition, or, in Great Britain, under the pressure of the Government, have been forced to adopt the most complete apparatus at great cost. In large city terminal stations, where additions to the space are out of the question, interlocking is necessary for economy of time and labour, as, indeed, it is in a less degree at smaller stations also; as a measure of safety, however, it is desirable at even the smallest, and the wise manager extends its use as fast as he is financially able. At crossings at grade level of one railway with another, and at drawbridges, interlocked signals with derailing switches obviate the necessity of stopping all the trains, as formerly was required by law everywhere in America, and saving a stop saves money. The block system was introduced primarily for safety, but where trains are frequent it becomes also an element of economy. Without it trains must usually be run at least five minutes apart (many managers deem seven or ten minutes the shortest safe interval for general use), but with it the interval may be reduced to three minutes, or less, according to the shortness of the block sections. With automatic signals trains are safely run at high speed only one and a half miles apart. Automatic signals are liable to dangerous failure from sticking of movable parts or from lightning; but records show that a series of signals properly cared for will fail only once in a million times (from all causes); and in view of the lower cost of the automatic, and its perfect adaptability to permissive signalling, makers and users of the system offer the defence that (1) not all failures cause collision; and (2) human attendants also make dangerous mistakes. The signal equipment of the largest railways costs from £100 to £1000 per mile. The electro-pneumatic on a four-track American line has cost \$5000 a mile, not counting interlocking plants. British manufacturers of signals (not railway companies) employ enormous capital. In America automatic signals have been developed at a cost of probably two or three million dollars; and the investment in interlocking represents a still larger sum. On the Continent and in India signalling development has followed that of Great Britain. The German and French lines have many signals, but the equipment of the several lines is far from complete, and the very numerous modifications which have been made in British theories by Continental engineers have not proved improvements, but quite the contrary.

(B. B. A.)

LOCOMOTIVE ENGINES.

Recent changes.

The increase in the weight and capacity of locomotives constitutes the most marked feature in their recent development all over the world. Many factors have contributed to this change. Two of the most important have been the increase of the axle-weight limit and the raising of the boiler above the ground to a sufficient height to allow of almost any desired dimensions of boiler and fire-box, independently of the width between the frames and the diameter of the driving wheels. The improvement in quality of steel boiler plate has permitted an increase in tractive effort with cylinders of a given diameter, and the substitution of cast steel for cast iron in details has reduced useless weight. The general tendency in railway working at the present time is towards higher average speeds with heavier trains, and this circumstance has forced attention to the importance of adequate boiler capacity combined with the highest efficiency of boiler and machinery, especially as the limits of weight and clearance dimensions are being rapidly reached. Clearance dimensions are those heights and widths which must not be exceeded by the engines, carriages, &c., running over a line if they are to avoid coming into contact with fixed structures, such as bridges, tunnels, and platforms. In America, as may be seen from Fig. 14,

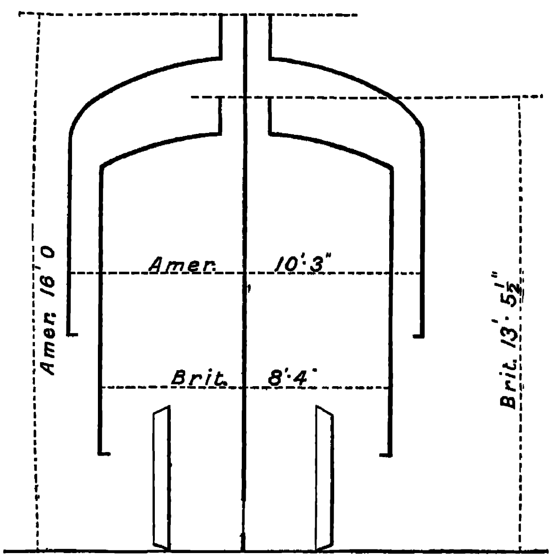

FIG. 14.—British and American clearance gauges.

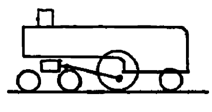
the maximum permissible measurements are considerably larger than they are in Great Britain, and this fact partially explains the superior size and weight of American engines as compared with British. It is not, however, the whole explanation, for British locomotive designers have not worked nearly up to the extreme dimensions possible until quite recently, and then only in comparatively few cases. Even first-class lines occasionally run some of their fastest and heaviest trains with engines whose designs are thirty years old, and which were suited to a time when the weights to be drawn were much smaller and the average of speed lower. The result is that the wasteful practice of using two engines to one train has frequently to be followed. Even so, there is frequently no reserve of power that will enable a driver to make up lost time; and once late, owing to whatever cause, the train continues so to the end of its journey. It is sometimes argued, however, that even when a driver has an engine capable of "playing with" the load behind it, he has no right to run faster than the speed indicated in his working time-tables, and that if an accident should happen when he was doing so, he might incur a grave legal responsibility. Still, of late years British railway engineers have come to recognize the advantages of ample locomotive power, just as the managers are perceiving the economy of big and full train loads; and recent designs, as may be seen from the examples given below in Table XVI., show increase in boiler capacity, in extent of heating surface, in steam-pressure (which in several cases now reaches 200 ℔ per square inch), in cylinder dimensions, and in adhesive weight. Increased production of steam is the problem that confronts the locomotive engineer, and he has attempted to solve it by the use of larger and longer boilers, and by the employment of various special devices. The employment of liquid fuel is also being tried by several railways in Great Britain, notably the Great Eastern (see PETROLEUM, § *Liquid Fuel*, vol. xxxi.).

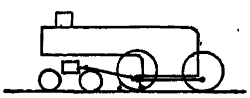
Classification.

Locomotives may be classified, according to the kind of service for which they are employed, into "passenger," "goods" or "freight," and "shunting" or "switching." These broad divisions include many types, which differ with the weight to be hauled, the character of the line, and the speed required, the selection of a type for a given duty being more or less controlled by the custom and tradition of the country. The two main factors governing a design are the required tractive effort and the speed, but locomotive types are best recognized and named according to the number and arrangement of the wheels used for driving. In the following synopsis the small diagrams are intended to indicate the arrangement, relatively to each other, of the boiler, wheels, and cylinders in the principal types into which locomotives may be classified:—

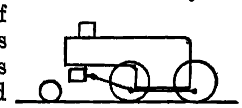
(1) "Single-driver" type. Still used by several railways in Great Britain for express passenger service, but going out of favour; it is also found in France, and less often in Germany, Italy, and elsewhere in Europe. It is frequently designed with three axles only, the driving axle being in the middle. It is adapted for light, high-speed service, and noted for its simplicity, excellent riding qualities, low cost of maintenance, and high mechanical efficiency; but having limited adhesive weight, it is unsuitable for starting and accelerating heavy trains.



(2) "Four-coupled" type, with leading bogie truck. For many years this was practically the only one used in America for all traffic, and it is often spoken of as the "American" type. In America it is still the standard engine for passenger traffic, but for goods service it is now employed only on branch lines. It has been extensively introduced, both in Great Britain and the Continent of Europe, for passenger traffic, and is now the most numerous and popular class. It is a safe, steady-running and trustworthy engine, with excellent distribution of weight, and it is susceptible of a wide range of adaptability in power requirements (see Table XVI., Nos. 1–7, 13, 19, 28, 31, and 34).

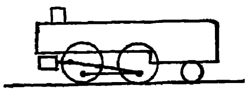


(3) "Four-coupled" three-axle type. Used to some extent in France and Germany and considerably in England for passenger traffic of moderate weight. Engines of this class, with 78-inch driving wheels and the leading axle (which is placed much farther back than is shown in the diagram) fitted with Webb's radial axle-box, for many years have been doing excellent work on the London and North-Western Railway. The famous engine "Charles

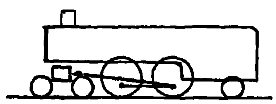


Dickens" was one of this class. Built in 1882, it had, by 12th September 1891, performed the feat of running a million miles in 9 years 219 days, and it completed two million miles on 5th August 1902, having by that date run 5312 trips with express trains between London and Manchester.

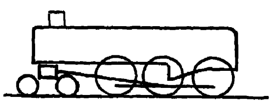
(4) "Four-coupled" three-axle type, with trailing axle. Used on several English lines for fast passenger traffic, and also on many Continental railways. The advantages claimed for it are: short coupling-rods, large and unlimited fire-box carried by a trailing axle, compactness, and great power for a given weight. Its critics, however, accuse it of lack of stability, and assert that the use of large leading wheels as drivers results in rigidity, and produces destructive strains on the machinery and permanent way.



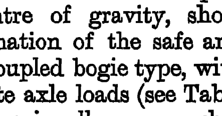
(5) "Four-coupled" type, with a leading bogie truck and a trailing axle. This was, in 1902, the most recent type for powerful express passenger service. It is used to a limited extent both in England and on the Continent, and is rapidly increasing in favour in the United States, where it originated and is known as the "Atlantic" type. It has many advantages for heavy high-speed service, namely, large and well proportioned boiler, practically unlimited grate area, fire-box of favourable proportions for firing, fairly low centre of gravity, short coupling rods, and, finally, a combination of the safe and smooth riding qualities of the four-coupled bogie type, with great steaming capacity and moderate axle loads (see Table XVI., Nos. 9, 10, 20, and 29). Occasionally a somewhat similar type is designed with the bogie under the fire-box and a single leading axle forward under the smoke-box—an arrangement in favour for suburban tank engines. In still rarer cases both a leading and a trailing bogie* have been fitted.



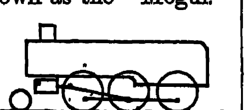
(6) "Six-coupled" with bogie, or "Ten-wheel" type (see Table XVI., Nos. 11, 12, 21, 30, and 35). A powerful engine for heavy passenger and fast goods service. It is used to a limited extent both in Great Britain and on the Continent, but is much more common in America. The design combines ample boiler capacity with large adhesive weight and moderate axle loads, but except on heavy gradients or for unusually large trains requiring engines of great adhesion, passenger traffic can be more efficiently and economically handled by four-coupled locomotives of the eight-wheel or Atlantic types.



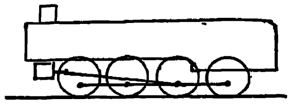
(7) "Six-coupled" total-adhesion type (all the weight carried on the drivers). This is the standard goods engine of Great Britain and the Continent. In America the type is used only for shunting. It is a simple design of moderate boiler power.



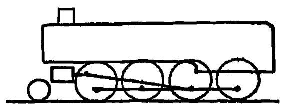
(8) "Six-coupled" type, with a leading axle. This is of American origin, and is there known as the "Mogul." It is used largely in America for goods traffic. On the Continent it is in considerable favour for goods and passenger traffic on heavy gradients. The type is, however, less in favour than either the Ten-wheel or the eight-coupled "Consolidation" for freight traffic (see Table XVI., No. 22).



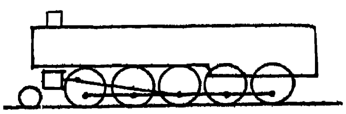
(9) "Eight-coupled" total-adhesion type; now found on a good many English railways and common on the Continent for heavy slow goods traffic. In America it is comparatively infrequent, as total-adhesion types are not in favour (see Table XVI., Nos. 14–17, 32, and 36).



(10) "Eight-coupled" type, with a leading axle. This originated in America, where it is termed the "Consolidation." In the United States it is the standard heavy slow-speed freight engine, and has been built of enormous size and weight. The type has been introduced in Europe, especially in Germany, where the advantages of a partial-adhesion type in increased stability and a larger boiler are becoming appreciated. The wide range in capacity and weight of this type in America is illustrated in Table XVI., Nos. 23–26. No. 25 is an example of a very powerful pusher locomotive for heavy gradients, and shows the application of the Wootten, or wide, shallow fire-box for burning fine anthracite or low-grade bituminous coal. Occasionally the American eight-coupled type has a bogie instead of a single leading axle, and is then termed a "Twelve-wheeler," or "Mastodon."



(11) "Ten-coupled" type, with a leading axle. This originated in America, where it is known as the "Decapod." It is used to a limited extent for mountain-grade goods traffic, and has the advantage over the "Consolidation" or eight-coupled type of lighter axle loads for a given tractive capacity.



In addition to the foregoing list, various special locomotive types have been developed for suburban service, where high rates of acceleration and frequent stops are required. These are generally tank engines, carrying their fuel and water on the engine proper. Their boilers are of relatively large proportions for the train weight and average speed, and the driving wheels of small diameter, a large proportion of their total weight being "adhesive." Other special types are in limited use for "rack-railways," and operate either by engagement of gearing on the locomotive into a rack between the track rails, or by a combination of this and rail adhesion (see the section below on *Mountain Railways*).

Table XVI., the data for which have been mostly supplied by the various railway companies in Great Britain and the different manufacturers in America, is intended to give some idea of the state of locomotive-building at the beginning of the 20th century, chiefly in Great Britain and America. While, therefore, it contains particulars of some recent engines of which only a few examples—perhaps only one—are in existence, it ignores some types which, although in extensive use, do not seem likely to be perpetuated, or which do not present any novel features. Nos. 1–18 are British engines, Nos. 19–27 American, and Nos. 28–36 Continental.

Comparison of locomotive practice.

Locomotives of similar type in the principal countries differ considerably in appearance and constructive detail. A broad distinction may be drawn between European and American practice in the framing and running gear. All American locomotives are built with bar or rectangular-section forged frames, and with a flexible system of levers and springs for equalizing, or distributing, the weight between the various axles. English and Continental locomotives, on the other hand, have side frames of plates braced together as a

rigid whole, and the weight is transmitted to the axles by independent spring supports, though equalizing levers are not entirely unknown. American locomotives of standard gauge invariably have the frames inside of the wheels, and outside cylinders, with solid integral saddles to carry the forward end of the boiler. British and Continental locomotives have the frames either inside or out, or both; and the cylinders are often inside, especially in Great Britain, the use of a cranked driving axle being a necessary incident of this practice. In American engines the height of the boiler from the ground and its larger diameter are noticeable features. The fire-box, too, is larger, and often placed above, instead of between, the frames; it is made of steel, not of copper as in Great Britain. An extended smoke-box is another characteristic of American practice, but one which is also to be found in Great Britain and the Continent. In proportions, American engines have much larger ratios of grate area and heating surface to cylinder volume than are found elsewhere, the difference being especially marked in contrast with British practice, and their actual dimensions and weight exceed those usual in other countries. High finish and absence of external pipes and visible mechanism are striking features of British engines, and to a less extent of those of the Continent. The aim of American designers is to have all moving and wearing parts accessible for quick inspection and repair, and appearance and finish are regarded as of secondary importance.

Elements of design.

(1) *Train Resistance* is a matter involved in much obscurity. It depends upon many variable conditions, such as the weather, track, kind and condition of equipment, as well as composition and weight of train. The formulæ given below presuppose that the trains are of average weight, and that the bearings are well lubricated and warmed by running; they also apply only after speeds of 12 miles an hour have been reached, since in starting a train from rest the frictional resistance is momentarily higher. On level straight track it should be taken at not less than 20 lb per ton of 2000 lb; this falls rapidly to the normal amount at a speed of say 2 miles an hour, but up to 12 miles an hour resistance should never be assumed at less than 5 lb per ton of 2000 lb. Train resistance may be expressed by the summation of the following factors:—

At a given speed	$Y_1 = \frac{S}{6} + 3$	(a)
Additional for gradients	$Y_2 = 0{\cdot}38\ M$	(b)
Additional for curves	$\left\{ Y_3 \begin{array}{l} = 0{\cdot}7\ C \text{ (for cars)} \\ = 1{\cdot}4\ C \text{ (for locomotive)} \end{array} \right\}$	(c)
Additional for acceleration	$Y_4 = 0{\cdot}0132V$	(d)
Or, for an increase in speed from a velocity V_1 to V_2	$Y_4 = 0{\cdot}0132(V_2^2 - V_1^2)$	(e)

In the above the resistances are in pounds per ton of 2000 lb of train weight, including the locomotive: S = speed in miles per hour; M = gradient in feet per mile; C = curvature in degrees; and V = velocity attained in one mile, starting from zero and expressed in miles per hour. Equations (d) and (e) include an allowance for energy stored in the rotating wheels.

A large number of the formulæ which have been suggested by various observers for the calculation of train resistances are collected in a paper on "Train Resistance," read before the Institution of Civil Engineers (London), on 26th November 1901, by Mr J. A. F. Aspinall, general manager of the Lancashire and Yorkshire Railway. This paper contains an account of numerous experiments carried out by the author with trains of various lengths, composed of the standard four-wheel-bogie passenger stock of that railway, and the general formula which he gives as expressing the results he obtained is

$$R = 2{\cdot}5 + \frac{V^{\frac{5}{3}}}{50{\cdot}8 + 0{\cdot}0278L},$$

where R = resistance in pounds per ton (2240 lb) drawn, V = velocity of train in miles per hour, and L = length of train in feet over the coach-bodies.

(2) *Tractive Effort.*—Theoretical tractive effort is represented by

$$T.\ E. = \frac{Pd^2S}{D}, \text{ in pounds} \quad . \quad . \quad . \quad . \quad . \quad . \quad (f)$$

where P = mean effective pressure in cylinders, in pounds per square inch; d = diameter of cylinder, in inches; S = stroke of piston, in inches; and D = diameter of driving wheels, in inches. For any given train, therefore, the following equation is true:—

$$\frac{Pd^2S}{D} = 1{\cdot}1(Y_1 + Y_2 + Y_3 + Y_4)T \quad . \quad . \quad . \quad . \quad . \quad (g)$$

where T = weight of train, including locomotive and tender, in tons of 2000 lb, 10 per cent. being allowed for internal friction of the engine. The tractive effort of a locomotive is greatest in starting, or at slow speeds; it is dependent upon the mean effective pressure in the cylinders, which is greatest at long cut-off when starting, and is generally assumed at 85 per cent. of boiler pressure for a maximum.

(3) *Steaming Capacity* is a variable factor, depending upon the type of boiler, combustion rate, character of fuel, &c. In good practice on heavy work the following are maximum results:—In express passenger service, with simple expansion cylinders, one-horse power for each two square feet of heating surface. In fast freight service, with simple expansion cylinders, one-horse power for each three square feet of heating surface. In heavy freight service, with simple expansion cylinders, one-horse power for each four square feet of heating surface. In express passenger service, with compound cylinders, one-horse power for each half square foot of heating surface. In the heaviest goods and passenger service a new limit for performance has been approached in the capacity of the stoker to shovel coal into the fire-box; 100 to 120 lb per minute appears to be the maximum practicable quantity.

Compound locomotives.

The era of compounding, as applied to locomotives, was inaugurated by Mr A. Mallet in 1876 in France, followed by Mr A. von Borries in Germany, Mr T. W. Worsdell and Mr F. W. Webb in England, and Mr S. M. Vauclain in America, all about the year 1889. Since the latter date the growth in use of the compound has been rapid, especially in America and France, in both of which countries it has passed the experimental stage. The same may be said of England so far as concerns the London and North-Western Railway, where many compounds on the Webb system are at work with satisfactory results; but on other lines, such as the North-Eastern, they are as yet scarcely more than experiments, though there are signs that such experiments will be widely tried in the near future.

The types proposed are many, and are known under the names of their designers. They may be classified (a) by the number of cylinders, two, three, or four; (b) by the number of main crank connexions, two or four; (c) by the peculiarities in starting mechanism, which may be either automatic or non-automatic; (d) by the use or not of a receiver between the cylinders.

The main types are represented by the "two-cylinder" (Mallet in France, von Borries in Germany, Worsdell in England); the "three-cylinder" (Webb and Johnson in England); and the "four-cylinder" (Mallet and de Glehn in France, Vauclain in America, Russia, &c., Webb in England). The four-cylinder designs are by far the most used, and appear to give the best results.

Important advantages are claimed for compounding, especially for modern powerful locomotives. The principal ones are:—

(a) Possibility of greater heat utilization by increasing the range of steam expansion, which is accomplished by successive expansion in two cylinders, instead of in one.

(b) Saving of steam by reduction of cylinder condensation, due to the lower range of temperatures resulting from less expansion in each cylinder.

(c) Better steam distribution by working at long cut-offs, thus avoiding the mechanical difficulties with valve motions at short cut-offs.

(d) Other mechanical advantages in certain types of multiple-cylinder compounds, such as the use of cylinders of smaller diameter, which with high pressure steam give a more uniform turning movement at the drivers than is possible in the two-cylinder simple engine.

(e) An important operating advantage obtained as the obvious result of the saving in fuel secured, namely, an

increase in the reserve capacity of the boiler for a given amount of work done by the engine.

The obtainable economy in fuel varies with service conditions, but the following may be expected as reasonable average results for compound as compared with simple locomotives having the same characteristics and used in the same kind of service:—

Passenger	10 to 15 per cent.
Goods	15 to 20 „ „
Heavy continuous grade goods .	25 to 40 „ „

It is very difficult to compare the cost of locomotives in various countries, because the specifications and material and weights vary. On the Continent of Europe it is customary to sell locomotives by weight, while in Great Britain and the United States they are sold at so much each. The cost of material causes fluctuations, apart from those which result from demand. We may, however, take as typical a British six-coupled goods engine and tender, with cylinders 18 by 24 inches. Such engines were sold in Great Britain in 1899 for about £3000. In the United States we may take as typical an eight-wheel or American-type locomotive and tender, with cylinders 17 by 24 inches. Such engines were sold in 1870 for about $12,750, in 1880 for $9000, in 1890 for $7000, and in 1900 for $8500. In the earlier years such an engine was unusually large and few were built. Now it is smaller than is ordinarily used in the United States. Further, even with the same size of cylinders these engines have increased in size and weight during the thirty years. In 1876 an eight-wheel American engine with cylinders 17 by 24 inches weighed about 72,000 lb; now it would weigh about 90,000 lb. Then the boiler was about 48 inches in diameter, now it is about 54. Steam-pressure has risen from 130 lb to 180 lb and more. In the United States the prices in the last quarter of 1900 were about $11,500 for a 60-ton Consolidation locomotive, $15,500 for a 90-ton Consolidation, and from $12,500 to $15,000 for a 75-ton Mogul or 10-wheel engine.

Cost of locomotives.

ROLLING STOCK.

Passenger Trains.—The passenger carriage of Great Britain and the Continent and the passenger car of the United States are unlike in many particulars. The carriage has, in general, transverse compartments, with side doors, and without a longitudinal passageway or end doors, although the recent introduction of corridor cars, having end doors and platforms, with communication through the car or train, suggests the probability of a general though gradual change of practice in that respect. The American passenger car has end doors only, with a central longitudinal passageway or aisle. In general the whole interior space is open; but just as the use of cars with end doors and through aisles is increasing in Great Britain and on the Continent, so the use of sleeping-cars divided into private compartments is increasing in the United States. Even in those cars, however, the end doors and through aisles are retained, and the number in use is not yet great enough to indicate a general change to the compartment plan, even for sleeping-cars. The relative merits of these two broad types of passenger-car design have been much discussed, but the question is too complicated to be considered here. It is enough to say that it is affected by the temperament, or at least by the rooted habits, of the peoples, by the methods of dealing with baggage, and by the division of passengers into classes.

The three classes, which originally were universal in Great Britain, have now been reduced to two on several important lines, by the abolition of the second class. Where this alteration has been effected, third-class passengers are carried by all trains, even the fastest, at a maximum rate of one penny a mile, and the practice of restricting certain expresses to first- or first- and second-class passengers only lingers on two lines in the South of England and in Ireland. On the Continent third-class passengers are still excluded from many of the faster trains, though there is a tendency towards increased liberality in this respect. The ordinary fares, however, are there appreciably lower than in Great Britain. In Hungary, Austria, and Russia a zone-tariff system is in operation, whereby the country is mapped out into zones, and the traveller pays according to the number of these he passes through, and not simply according to the number of miles he is conveyed. For example, on Russian railways, for any distance up to 6 versts (=4 miles), there is a minimum fare of 23 kopecks first class, 14 kopecks second class, and 9 kopecks third class. For distances between 6 and 300 versts, the charge progressively increases verst by verst, though at a gradually diminishing rate, so that, for instance, the first-class fare for 300 versts (8 roubles 90 kopecks) is less than twice that for 150 (5 roubles 40 kopecks). For distances greater than 300 versts, the fares increase by zones; these vary in length, but the increment of price is the same for each, whatever its length, namely, 50 kopecks first class, 30 kopecks second class, and 20 kopecks third class. The zones are 25 versts long between 301–500 versts, 30 between 501–710 versts, 35 between 701–900 versts, 40 between 901–1510 versts, and 50 for greater distances. By a change which came into effect in May 1902, the 50-verst zones extend only from the 1511th to the 3010th verst, and for greater distances the zones contain 70 versts. The charges on these are increased to 100 kopecks first class, 60 kopecks second class, and 40 kopecks third class. In America there is nominally one class, the average fare being about 1⅛d. per mile, but the extra charges levied for parlour, sleeping, and other cars practically constitute a differentiation of class, besides making the real cost of travelling higher than that just given. Immigrants are carried in special trains at much lower rates.

In America and other countries where long distances have to be travelled and passengers have to spend several days continuously in a train, sleeping-cars, restaurant-cars, smoking-cars, &c., become almost a necessity, and accordingly are to be found as a matter of course on most of the best through trains. On the continent of Europe they are largely in the hands of the International Sleeping-Car Company, and the charges for such accommodation *de luxe* frequently constitute a very heavy addition to the ordinary distance rates levied by the railways. In England, where the distances are comparatively small, sleeping and restaurant cars must rather be regarded as luxuries; still, even so, they are very frequently to be met with. The Midland Railway was the first to run sleeping-cars on its trains, the innovation being due to Sir James Allport about 1875. The earliest were Pullman cars imported from America; but when other lines began to adopt them, they were made in England with such differences as commended themselves to the various designers. In the most recent type a side corridor runs the whole length of the vehicle, and terminates in a vestibule platform at either end, so that communication

Dining and sleeping cars.

may be had with the adjacent coaches. Off this corridor open small compartments or berths, made for one or two persons only, each being fitted with a folding lavatory similar to that found in a ship's cabin. Sleeping-cars are run on most of the important night trains between London and Scotland, Manchester, Liverpool, Holyhead, &c., and are available for passengers holding first-class tickets on payment of a uniform fee of five shillings. Such cars for third-class passengers have frequently been talked about, but have yet to make their appearance on any British railway. The number of restaurant-cars increased greatly about the end of the 19th century; and whereas at first they were attached only to two or three expresses, mostly running between London and Scotland, they are now frequent on trains covering much shorter distances, *e.g.*, between London and Lancashire, Birmingham, Cromer, &c. The introduction of corridor trains has greatly extended their usefulness, and, without extra charge beyond the amount payable for food, they are provided for all classes, except on the Great Western Railway, which, although early in the field as regards corridor trains, for long excluded all but first-class passengers from its dining-cars, which, moreover, were very limited in number. However, the introduction in 1901 of corridor trains and dining-cars for all classes by its great rival, the London and South-Western Railway, compelled a change in its policy, and in 1902 orders were given for dining-stock for second- and third-class passengers.

Construction of carriages.

European carriages were at first mounted on two, and later on three, axles, which were free to rise and fall through a limited range, but not to turn with respect to the carriage. Thus the length of the body was limited, for to increase it involved an increase in the length of the rigid wheel-base, impossible with due regard to safety. Hence bogies or swivel trucks, which allow of longer car bodies, are fast coming into use; indeed, the standard coaching stock of Great Britain is now carried on bogies. The American passenger car has invariably been mounted on swivel trucks, having four wheels each for ordinary cars and six wheels each for sleeping, postal, and other heavy cars.

A noteworthy feature in British practice has been the large increase in the weight of passenger vehicles, both absolutely and still more in relation to the number of persons they can accommodate. The result, which is attributable in great part to the lavatories now general, and to the introduction of corridor carriages, is reflected in the heavier trains run, and in the larger and more powerful locomotives that must be provided to haul them. Some idea of the extent to which rolling stock has increased in weight and decreased in capacity may be gained from the official figures, as given in Table XVII., of the standard stock in use on the Midland Railway in 1901, if they are compared with those in the similar table to be found in the article RAILWAYS in the ninth edition of this Encyclopædia (vol. xx. p. 248). Thus a standard bogie third-class passenger coach in 1885 weighed 17¾ tons and held 70 persons; in 1901 the weight had risen to almost 25 tons and the capacity fallen to 36 persons.

Heating and lighting.

As a result of early practice in bridge, station, and tunnel construction, British and Continental carriages cannot be made as large as American passenger cars; though the restriction is less on the Continent than in Great Britain (see Fig. 14 for clearance gauges). One consequence is that larger cubic capacity per passenger is possible in the United States—a fortunate circumstance, since the greater range of temperature there makes proper heating and ventilation relatively more important and at the same time more difficult. In the United Kingdom the ancient system of hot-water cans[1] is still largely employed for heating, but in the United States much the most common method is by steam taken from the boiler of the locomotive and circulated through the train by a line of piping connected by flexible couplings between the cars—a method which is also finding increased favour in Europe. As to lighting, the feeble glimmer of the oil lamp is still to be seen in some English railway carriages, but it has mostly been displaced by gas and electricity. The former is a rich oil gas, compressed and stored in steel reservoirs under the carriages. The latter is obtained from dynamos driven from the axles of the coaches. In block-trains, where the component coaches are permanently coupled together, one dynamo sometimes lights all the carriages; but usually each has its own dynamo, and so becomes an independent unit. In the system most commonly employed in England the dynamo is connected to the axle in such a way that its speed, and consequently the current it yields, is approximately constant, whatever the speed of the train. In another system, which is of American origin, the required constancy of current is provided for by means of an automatic switch, which adds to or takes away resistance from the field-coils of the dynamo according as the speed of the train rises or falls. In both systems accumulators are used to maintain the light when the train is at rest or travelling too slowly to admit of current being generated. Gas and electric lighting are also extensively resorted to in American and Continental trains; but up to 1902 compressed oil-gas was very much more common than electric lighting, and in the United States kerosene-oil lamps were still extensively employed.

TABLE XVII.—*Details of Midland Railway Stock.*

Carriage.	Length of Body.	Compartments.						Number of Passengers.		Weight.

Communication with guard.

In Great Britain the railway companies are by the Regulation of Railways Act, 1868, required to fit trains which run more than 20 miles without a stop with some means of communication between the passengers and the officials in charge. With the system of separate carriages this is not an easy matter to accomplish satisfactorily. On some lines electrical devices have been in use for many years, but the most common method has been a continuous cord running along the whole length of the train outside and above the carriage windows, which, when pulled down, was supposed to give an alarm signal to the guards and engine-driver. The arrangement had many disadvantages, not the least being that it frequently failed to act. Recently a number of the railway companies have decided

[1] These cans in many cases do not contain water, but fused acetate of soda. When cold, the contents are solid; but when they are heated by being immersed in hot water, they liquefy, and in the process absorb heat, which is given out again on the change of state back to solid. Hence the cans remain warm for a very long time.

to adopt a modification whereby the cord, which runs along the cornice inside the compartments, is continuous through each carriage but not through the train, and is connected to the air-brake apparatus, so that, when pulled down, it puts the brakes on sufficiently to attract the attention of the driver. In the corridor trains, attendants can pass freely from one end to the other, and a system of electric bells enables the passenger to summon them at will.

There is a broad difference in practice in making up passenger vehicles into trains, which has come about partly because of the different mode of handling luggage. In the United States the passenger claims his luggage at the luggage-room of the station, or more often gives his receipt ("check") to a third party, and only sees his luggage at his hotel or house. Hence the luggage going by any one train is concentrated in one or more special vehicles ("baggage cars"), placed at or near the head of the train; this is also true of Continental practice. Here also will often be found in the United States the "express car," which carries such packages as in other countries are carried by parcel post or by fast goods trains at special rates. Here will often be found also a huge post-office car. Then follow, in order as mentioned, a smoking-car, ordinary day-cars (often called coaches), parlour-cars, sleeping-cars, and, finally, a dining-car. Dining, sleeping, and postal cars have no place in trains making short runs. In the United Kingdom passenger trains often contain vehicles which are never seen in the United States and seldom on the Continent, namely, horse-boxes and carriage-trucks. These are a part of the thorough organization for comfort and convenience in railway travelling which is probably more complete in the British Islands than anywhere else in world.

Weight. A comparison of the weights of passengers trains in Europe and the United States is difficult to make. In all countries trains of different weights are used according to the different services they are required to perform, and it would obviously be improper to compare a long-distance fast train, with sleeping or dining cars, with a slow short-distance train, carrying nothing but passengers. Moreover, the weight of a train timed to leave a given station at a particular time may vary from season to season, and even from day to day, according to the number

of coaches required to accommodate the traffic. For short and middle distances probably the usual weight of trains varies between about the same limits in all countries; for long distances the necessity of providing sustained arrangements for living on the journey tends to increase of weight, and therefore in extensive countries like the United States heavier trains may be found than in small ones like Great Britain. At the same time, there are some long-distance trains in Great Britain quite as heavy, if not heavier than some in the United States, even though the average weight of rolling stock is distinctly greater in the latter country. General conclusions, except of the vaguest character, are therefore almost impossible, and the best that can be done is to consider specific instances. A number of these have been collected in Table XVIII., which gives some of the best and heaviest trains run in the two countries. In using it, the reader must remember that the weight of a particular train may vary not only initially from day to day, owing to variation of traffic, but also on any one journey from station to station, owing to carriages being added or taken away.

Speed. A comparison of average speeds is scarcely less difficult than of average weights. In 1888 a careful study was made of express train mileage in the United Kingdom, on the Continent, and in the United States. For the United Kingdom and the United States 40 miles an hour, including stops, was taken as express train speed, *i.e.*, an average rate of 40 miles an hour from the beginning of the journey to the end. But on the Continent so few trains reached this rate of travelling that the arbitrary speed of 29 miles was taken there for express speed. It was found that in the United Kingdom trains ran 62,900 miles every day at and over 40 miles an hour, and in the United States 13,956 miles, while on the Continent of Europe trains ran 118,000 miles at and over 29 miles an hour, but at and over 40 miles an hour there was something less than 9000 miles a day on the entire Continent. Since that date an important change has taken place in Great Britain, the United States, France, and Germany. In all these countries faster trains are run, and the average express speed has been raised. The fastest trains are no longer run in Great Britain, but in America, by the Philadelphia and Reading Railway between Philadelphia and Atlantic City, in competition with the Pennsylvania Railroad. Passengers are conveyed from Philadelphia by ferry-boat across the river Delaware to Camden, whence the distance to Atlantic City by the Philadelphia and Reading Company's lines is 55½ miles. This is covered by some trains in 50 minutes; the booked speed thus is 66·6 miles an hour, and on some occasions an average speed of over 71 miles an hour has been maintained from start to stop. By the Pennsylvania Railroad Company's system the distance between Camden and Atlantic City is 58 miles, and trains weighing about 160 tons, exclusive of engine, are booked to perform the journey at the rate of 64·4 miles an hour. In Great Britain, on the Caledonian Railway from Forfar to Perth, one train covers 32½ miles in 33 minutes (59·09 miles an hour), and on the North-Eastern Railway a train runs from Darlington to York (43¾ miles) in 43 minutes (61·04 miles an hour). In France, also, instances may be found of trains timed over 60 miles an hour, *e.g.*, Paris to Arras 120 miles in 117 minutes. Of course still higher speeds, up to 75 and even 80 miles an hour, are reached and sustained for shorter or longer distances every day by express trains, the average speed of which between any two stopping-places is very much less. But isolated examples of high speeds afford little information as to the train service at the command of the traveller in different countries, for it is obvious that his convenience will be better served by a large number of trains, all maintaining a good average of speed, than by a service consisting mostly of poor trains, with only one or two exceptionally fast ones. From this point of view Great Britain remains ahead of all other countries. To give exact numerical expression to this superiority is impossible, but Table XIX. will supply a general idea of the volume and speed of express traffic in different countries. No train has been included which does not run daily (except Sundays) and travel at least 40 miles an hour on the average, inclusive of stops. This limitation excludes many trains which are called "fast" and "express," both in the United States and on the Continent, but even if the speed necessary to gain admission to the table were reduced by a good many miles an hour, Great Britain would still hold the first place if the number of high-speed trains is taken into account as well as the average of speed attained:—

* Including trains that pass through Rugby without stopping.

Goods Trains.—The vehicles for the transportation of goods are known as goods waggons or trucks in Great Britain and on the Continent, and as freight cars in America. The principal British and Continental types are open trucks or waggons (the lading often covered with sheets), mineral trucks, and covered or box waggons fo

cotton, grain, &c. The American freight cars of the principal types are known as box cars, gondola cars, coal cars, stock cars, tank cars, and refrigerator cars. Most of these terms explain themselves. The gondola car corresponds to the European open waggon, and is used to carry goods not subject to injury by the weather; but in the United States the practice of covering the load with tarpaulin sheets is unknown, and therefore the proportion of box cars is much greater than in Europe. Indeed, the long hauls in the United States make it even more important there than in other countries to load cars in both directions, and so it has come about that for the return journey coal, coke, ore, lumber, and other coarse articles are loaded into box cars that have carried grain or merchandise one way. It is common to put small end doors in American box cars, through which lumber and rails may be loaded. The fundamental difference between American freight cars and the goods waggons of Europe and all other lands is in carrying capacity. This difference is interesting as an example of development under the influence of surrounding conditions. Indeed, the American freight car is so unlike those of other countries that comparisons are difficult. In the United Kingdom the average carrying capacity of goods waggons must be under 10 tons, perhaps about 8 tons, and the capacity of heavy mineral trucks is 11 tons. On the Continent the average carrying capacity is a little over 10 tons; there are many cars still in service of less than 10 tons' capacity, but much the greater number are rated at 10 tons, while large numbers of 15-ton cars have been built within a few years, and the tendency is to raise the capacity. These are all short cars with four wheels. Freight cars in the United States have long bodies on two swinging trucks of four wheels each, and their average capacity is quite three times as great as that of European waggons. For years the standard freight car has been of 30 tons' capacity (short tons, 2000 lb); in recent years many 40-ton cars have been put in service; and still more recently several thousand cars have been built of 50 and even 55 tons' capacity. This great carrying capacity of the freight cars in the United States has worked in several ways to make possible those very low freight rates mentioned in the introduction to this article. It has diminished the ratio of non-paying to paying load; it has diminished the interest on first cost and cost of maintenance relatively to the work done; it has diminished in some degree, probably small, the amount of track and yard room required to do a unit of work; it has diminished journal and rolling friction relatively to tons hauled, for these elements of train resistance grow relatively less as the load per wheel rises; finally, and most important of all, the wages element has fallen as train loads have grown greater, since no more men are required to handle a heavy train than a light one.

Size and construction of trucks.

It is often said that if these things are true for one country they must be true for another, and that in Great Britain, for example, the use of more capacious cars would bring down the cost of goods carriage. This is not the place to debate a controverted question, but it may be pointed out that social and geographical conditions are different in the United States and the United Kingdom, and in each country the methods of conveying goods and passengers have been developed according to the requirements of those conditions. In one country the population is dense, large towns are numerous and near each other, the greatest distances to be traversed are short, and relatively a large part of the freight to be carried is merchandise and manufactured material. In the other country precisely the opposite conditions exist. Under the first set of conditions quickness and flexibility of service are relatively more important than under the second set; therefore goods are collected and despatched promptly, in numerous cars, often only partly loaded. But where the great volume of freight is raw material and crude foodstuffs, and the distances are great, a low charge per unit of transportation is more important than any other consideration; therefore freight is massed into full car loads and enormous trains, and sent perhaps 1000 miles to a distributing-point, or to a seaport. At the same time it must be noted that several British railway companies are experimenting with trucks of large capacity, similar to those used in America, but appear to find some trouble in getting full loads for them.

Weight and speed.

The differences in the carrying capacity of freight cars in Europe and the United States have brought about the differences in the make-up of freight trains. Here, as with passenger trains, averages mean little, but typical special cases give useful comparisons. In Great Britain we find, on six of the great railways, mineral trains (*i.e.*, trains carrying coal, coke, and ore) which weigh (trucks and load, but not the engine) from 525 to 765 tons. These weights, however, are in some cases greatly exceeded. Several British railways have engines capable of hauling loads of 1000 tons; and on the North-Eastern one (No. 15 in Table XVI.) has taken a train of 81 loaded trucks and one van, weighing $1326\frac{1}{4}$ tons and nearly a third of a mile in length, up a bank of 1 in 108 at the worst point, where also there was a curve of 20 chains' radius. The speed of such mineral trains, like the weight, varies with the gradients and other conditions, and they may be timed from 10 to 30 miles an hour, not counting time spent on sidings. The fast goods trains carry lighter loads and run faster; on the same lines these vary from 214 to 460 tons and make 25 to 30 miles an hour, the speeds rising so high as 37 miles an hour for short distances, and falling so low as 13. In Prussia an example of good practice for the various classes of goods trains gives weights from 900 to 1100 tons, and speeds (terminus to terminus) of 11 to 21 miles an hour, according to load and gradient. In the United States mineral and grain trains weigh from 1500 to 3800 tons (2240 lb), and 2000 tons would be only fairly good practice for this class of traffic. These trains are necessarily and properly very slow, being timed at 10 or 12 miles an hour. The merchandise trains of the United States are lighter and faster than those carrying coal, ore, salt, &c.; and this is true also of the important classes of trains which carry live stock, fruit, and dairy products, and dressed meat in refrigerator cars. It is obvious that the weight and speed of these trains must vary with topographical conditions. In the great continental basin are long lines with easy gradients and curves; in the Allegheny and Rocky Mountains gradients are heavy and curves are numerous and of short radius. We find, therefore, that the trains of which we are now speaking weigh from 600 to 1800, and even 2000 tons, and the journey speeds, from terminus to terminus, including stops, vary from 15 to 30 miles an hour. It is not uncommon for these trains to maintain, for considerable distances, 40 miles an hour; and managers of some of the most important prairie lines estimate that their freight trains often run over a mile a minute for many miles at a time. Such speeds for freight trains of 1000 tons or more demand great engine-power, the best couplings, and high-power continuous brakes. (See BRAKES.)

Couplings.—The means generally employed for connecting freight cars or goods waggons, one to the other, are not automatic; that is, men must go between the vehicles to couple or uncouple them, or at best can only avoid doing so by the use of a stick to guide the coupling link to its

place. As a result, many men have been killed or maimed in the performance of their duties in railway yards, and a great body of public opinion has grown up which calls for automatic couplers, and has found expression in agitation, invention, and legislation. In the United States an automatic freight car coupler is used on possibly 90 per cent. of freight stock. To effect this took more than twenty-five years of discussion and experiment. The Master Car Builders' Association, which is a great body of mechanical officers organized especially to bring about improvement and uniformity in details of construction and operation, expressed itself in 1874 as understanding the importance of a "self-coupler," but none had then been invented which could be considered as useful. At that time a member of the Association spoke of the disappearance of automatic couplers which had been introduced thirty or forty years before. This body pursued the subject with more or less diligence, and in 1884 laid down the principle that the automatic coupler should be one acting in a vertical plane; that is, the engaging faces should be free to move up and down within a considerable range, in order to provide for differences in the height of cars brought together. This principle having been fixed, the task of the inventor was considerably simplified. In 1887 a committee reported that the coupler question was "the knottiest mechanical problem that had ever been presented to the railroad," and over 4000 attempted solutions were on record in the United States Patent Office. The committee had not found one which did not have grave disadvantages. In 1887, however, the Association recommended the adoption of a coupler of the Janney type, and this coupler as it has developed is shown in Fig. 15.

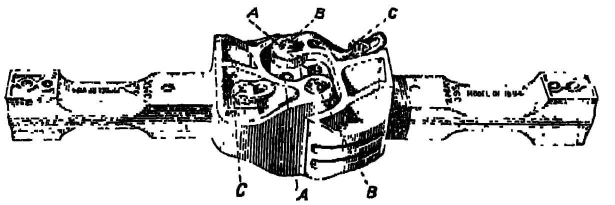

FIG. 15.—Automatic coupling for freight cars (U.S.A.).

The committee concluded that "the principle of contact of the surfaces of vertical cylinders embodied in the Janney coupler affords the best connexion for cars on curves and tangents." The method of constructing the working faces of the Janney coupler is shown in Fig. 16, which illustrates

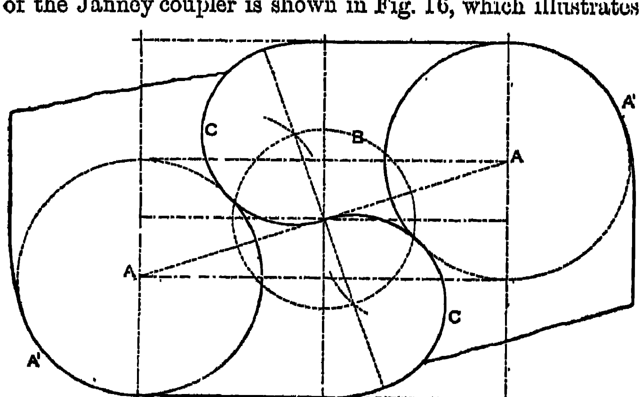

FIG. 16.—Development of the working faces of the Janney coupler. The sides of the square are 6 inches, and the centres AA are taken at 2 inches from the top and bottom of the square. The circles A'A', which are struck with 2-inch radius, define the first portion of the knuckle. The inner circle B has a radius of 1½ inches. From its intersection with A'A' arcs are struck cutting B in two points. These intersections determine the centres of the semicircles CC which form the ends of the respective knuckles. These semicircles and the circles A'A' are joined by tangents and short arcs struck from the centre of the figure.

the principle of contact of vertical cylinders. This principle was patented, but the company owning the patent undertook to permit its free use by railway companies which were members of the Master Car Builders' Association, and thus threw open the underlying principle of this coupler to competition. From that time the numerous patents have been merely on details. There are fifteen different couplers of the Janney type, patented and made by as many different concerns, each of which is used on at least 10,000 cars, and, in addition, many other forms are in less extensive use. The movement towards the use of an automatic coupler was stimulated in some degree by laws enacted by the various states and by the United States; and in 1893 Congress passed an Act, one clause of which required railway companies to have their freight cars equipped with automatic couplers by January 1898. The Interstate Commerce Commission, which has discretion in the matter, extended the limit to 1st August 1900.

The coupler in general use outside of the United States is a chain and hook, with spring buffers, which, however, are no part of the coupler itself. In the United States the universal coupler, which has now almost disappeared, was the "link-and-pin" coupler, in which a draw-bar is spring-connected to the frame of the car. The out-board end of this draw-bar is a socket, into which one end of a solid link is inserted, and the pull is exerted on a pin dropped through this link. The first strain of compression, when the cars close together, is also taken on this draw-bar and transmitted back through the springs to the frame of the car. Thus there is a fundamental difference between American and European practice in that in the United States the coupler is also a buffer.

The essential change from the link-and-pin to the automatic coupler is in the out-board end or head of the draw-bar. The socket to receive the link is replaced by a hook, shown at A, Fig. 15, which is usually called the knuckle. This hook swings on the pivot B. It has an arm which extends backwards, practically at right angles with the working face of the hook, in a cavity in the head, and engages with the locking-pin C. This locking-pin is lifted by a suitable lever, which extends to one side or to both sides of the car. Lifting the locking-pin releases the knuckle, which is free to swing open, disconnecting the two cars. The knuckle stands open until the coupling is pushed against another coupling, when the two hooks turn on their pivots to the position shown in Fig. 15, and the locking-pin drops into place and the couplers are made fast. This coupler is only partly automatic. It often happens that when two cars are brought together to couple, the knuckles are closed and must be opened by hand. There are various contrivances by which this may be done by a man standing clear of the cars, but in most cases he must go between the cars to reach the knuckle. This defect will no doubt be corrected by comparatively simple means. This form of automatic coupler is the only one used to any extent in the United States, where it is now practically universal, and no reason now appears why any other should be used there. It has been adapted to British and Continental rolling stock in a few instances for experiment, but whether or not it will be found acceptable cannot be foretold. The tendency in Great Britain is perhaps rather towards some non-automatic form of coupling which can be safely coupled and uncoupled without the necessity of men going in between the waggons.

Another question which is attracting the attention of inventors and railway companies in England is the problem of fitting waggons with hand-brakes which can be applied and released from either side of the waggon indifferently. The old form of brake is worked by a lever which is fitted at one side only, and thus the men, in order to work the brake, often have to incur the danger of passing

under the waggons. The Board of Trade has power, under the Prevention of Accidents Act of 1900, to insist on all waggons being fitted with "either-side" brakes. (See above, p. 137.)

Vestibules for Passenger Cars.—End platforms and end doors have always been characteristic of American passenger equipment, and are extending to British and Continental carriages. Their use secures a continuous passageway through the train, but is attended with some discomfort and some risk when the train is in motion. The opening of the end doors may make a draught through the car, disagreeable in cold weather, and passengers occasionally fall from the open platform, or are blown from it, while the train is moving. The first object of the vestibule is to enclose the platform with a housing so arranged as to be continuous when cars are made up into trains, and fitted with side doors for ingress and egress when trains are standing. A second effect of the vestibule has developed in use. It appears that the lateral swaying of the cars is diminished by the friction between the vestibule frames. The fundamental American vestibule patent, issued to Mr H. H. Sessions, of Chicago, in November 1887, covered a housing in combination with a vertical metallic plate frame of the general contour of the central passageway, projecting slightly beyond the coupling line, and held out by horizontal springs top and bottom; the plate frame being connected with the platform housing by flexible connexions at the top and sides,

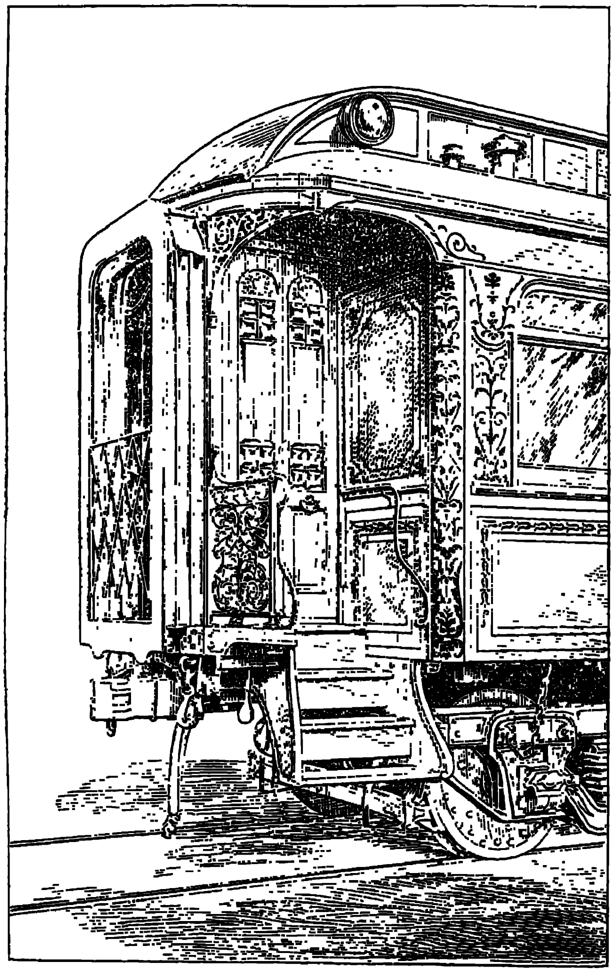

FIG. 17.—A "Vestibule"; the "lazytongs" gate is folded away when two cars are coupled together, giving free passage from end to end of the train.

and by sliding plates below. A common form of this vestibule is shown in Fig. 17. Subsequent improvements on the Sessions patent have resulted in a modified form of vestibule in which the housing is made the full width of the platform, although the contact plate and springs, and the flexible connexions, remain the same as before. On long journeys the vestibule is a convenience and a comfort; but its application is practically limited to the cars which are run in such trains, as it is an obstruction to the free ingress and egress of passengers on local trains which make frequent stops.

Of American cars intended to carry passengers, the proportion equipped with vestibules in September 1900 was about as follows: cars owned by railway companies, 15 per cent.; cars owned by the Pullman Company, 75 per cent. It appears probable that the application of vestibules will continue until the following maxima are reached: railway companies, 25 per cent.; Pullman Company, 100 per cent. (H. G. P.; R. H. So.)

INTRA-URBAN RAILWAYS.

Development. The great concentration of population in cities during the 19th century brought into existence a class of railways to which the name of intra-urban may be applied. Such lines are primarily intended to supply quick means of passenger communication within the limits of cities, and are to be distinguished on the one hand from surface tramways, and on the other from those portions of trunk or other lines which lie within city boundaries, although the latter may incidentally do a local or intra-urban business. Intra-urban railways, as compared with ordinary railways, are characterized by shortness of length, great cost per mile, and by a traffic almost exclusively passenger, the burden of which is enormously heavy. For the purpose of connecting the greatest possible number of points of concentrated travel, the first railways were laid round the boundaries of areas approximately circular, the theory being that the short walk from the circumference of the circle to any point within it would be no serious detention. It has been found, however, in the case of such circular or belt railways, that the time lost in traversing the circle and in walking from the circumference to the centre is so great that the gain in journey speed over a direct surface tramway or omnibus is entirely lost. Later intra-urban railways in nearly every case have been built, so far as possible, on straight lines, radiating from the business centre or point of maximum congestion of travel to the outer limits of the city; and, while not attempting to serve all the population through the agency of the line, make an effort to serve a portion in the best possible manner, that is, with direct transit.

The actual beginning of the construction of intra-urban railways was in 1853, when powers were obtained to build a line, $2\frac{1}{4}$ miles long, from Edgware Road to King's Cross, in London, from which beginning the Metropolitan and Metropolitan District railways developed. These railways, which in part are operated jointly, were given a circular location, but the shortcomings of this plan soon became apparent. It was found that there was not sufficient traffic to support them as purely intra-urban lines, and they have since been extended into the outskirts of London to reach the suburban traffic.

The Metropolitan and Metropolitan District railways followed the art of railway building as it existed at the time they were laid out. Wherever possible the lines were constructed in open cutting, to ensure adequate ventilation; and where this was not possible, they were built by a method suggestively named "cut and cover." A trench was first excavated to the proper depth, then the side walls and arched roof of brick were put in place, earth was filled in behind and over the arch, and the surface of the

ground restored, either by paving where streets were followed, or by actually being built over with houses where the lines passed under private property. Where the depth to rail-level was too great for cut-and-cover methods, ordinary tunnelling processes were used; and where the

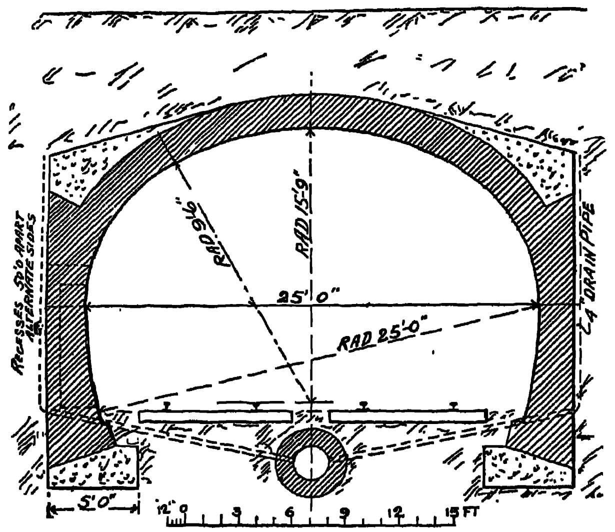

FIG. 18.—Type-section of arched covered way, Metropolitan District Railway, London.

trench was too shallow for the arched roof, heavy girders, sometimes of cast iron, bridged it between the side walls, longitudinal arches being turned between them (Fig. 18).

The next development in intra-urban railways was an elevated line in the City of New York. Probably the first suggestion for an elevated railway was made by Colonel Stevens, of Hoboken, New Jersey, as early as 1831, when the whole art of railway construction was in its infancy. He proposed to build an elevated railway on a single line of posts, placed along the curb line of the street, a suggestion which not only embodies the general plan of an elevated structure, but the most striking feature of it as subsequently built, namely, a railway supported by a single row of columns. The first actual work, however, was not begun till 1870, when the construction of an iron structure on a single row of columns was undertaken. The superiority, so far as the convenience of passengers is concerned, of an elevated over an underground railway, when both are worked by steam locomotives, and the great economy and rapidity of construction, led to the quick development and extension of this general design. By the year 1878 there were four parallel lines in the City of New York, and constructions of the same character had already been projected in Brooklyn and Chicago and, with certain modifications of details, in Berlin. In the year 1894 an elevated railway was built in Liverpool, and in 1900 a similar railway was constructed in Boston, U.S.A., and the construction of a new one undertaken in New York.

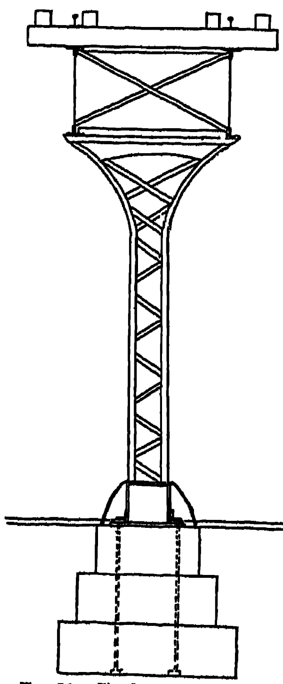

FIG. 19.—Single-column elevated structure.

These elevated railways as a rule follow the lines of streets, and are of two general types. One (Fig. 19), the earliest form, consisted of a single row of columns supporting two lines of longitudinal girders carrying the rails, the lateral stability of the structure being obtained by anchoring the feet of the columns to their foundations. The other type (Fig. 20) has two rows of columns connected at the top by transverse girders, which in turn carry the longitudinal girders that support the railway. In Berlin, on the Stadtbahn, which for a part of its length traverses private property, masonry arches, or an earthen embankment between retaining walls, were substituted wherever possible for the metallic structure.

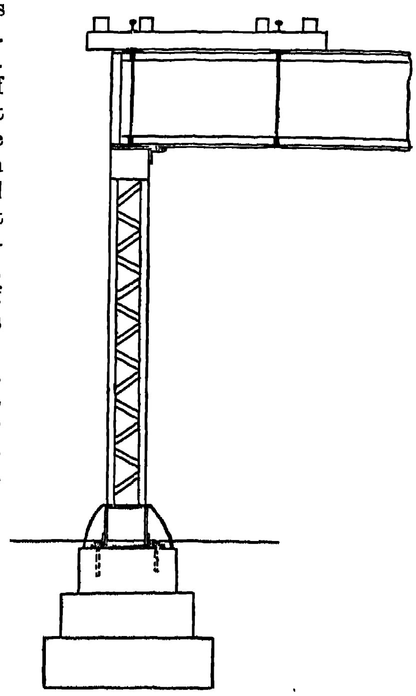

FIG. 20.—Double-column elevated structure (half-section).

The next great development, marking the third step in the progress of intra-urban railway construction, took place in 1886 when Greathead (*q.v.*) began the City and South London Railway, extending under the Thames from the Monument to Stockwell, a distance of 3½ miles. Its promoters recognized the unsuitability of ordinary steam locomotives for underground railways, and intended to work it by means of a moving cable; but before it was completed, electric traction had developed so far as to be available for use on such lines. Electricity, therefore, and not the cable, was installed (Fig. 21). In the details of construction the shield was the novelty. In principle it had been invented by Brunel for the construction of the original

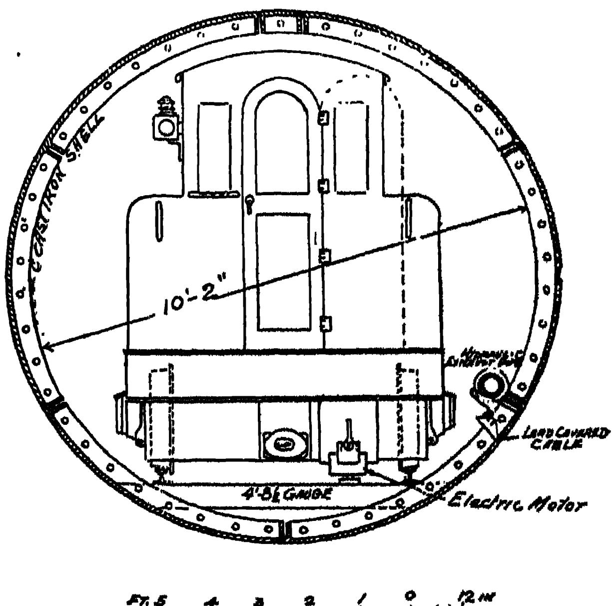

FIG. 21.—Section of tunnel and electric locomotive, City and South London Railway.

Thames tunnel, and it was afterwards improved by Beach, of New York, and finally developed by Greathead. (For the details of the shield and method of its operation, see TUNNELLING.) By means of the shield Greathead cut a circular hole at a depth ranging from 40 to 80 feet below the surface, with an external diameter of 10 feet 9 inches; this he lined with cast-iron segments bolted together, giving a clear diameter of 10 feet 2 inches. Except at the shafts, which were sunk on proposed station sites, there was no interference with the surface of the streets or with street traffic during construction. Two tunnels were built approximately parallel, each taking a single track. The cross-section of the cars was made to conform approximately to the section of the tunnel, the idea being that each train would act like a piston in a cylinder, expelling in front of it a column of air, to be forced up the station shaft next ahead of the train, and sucking down a similar column through the station shaft just behind. This arrangement was expected to ensure a sufficient change in air to keep such railways properly ventilated, but experience has proved it to be ineffective for the purpose. This method of construction has been used for building other railways in Glasgow and London, and in the latter city alone projects for "tube railways" of this character were brought before Parliament in 1902, which involved a capital of about 100 millions. One of the largest of these was for a line running from the terminus of the London United Tramways at Hammersmith, through the heart of the City, to the north-east suburbs. The later examples of these tube railways have a diameter ranging from 13 to 15 feet.

The fourth step in the development of intra-urban railways was to go to the other extreme from the deep tunnel which Greathead introduced. In 1893 the construction was completed in Budapest of an underground railway with a thin, flat roof, consisting of steel beams set close together, with small longitudinal jack arches between

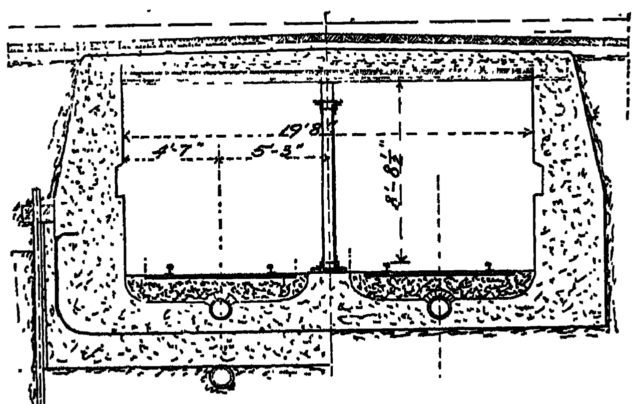

FIG. 22.—Electric underground railway, Budapest.

them, the street pavement resting directly on the roof thus formed (Fig. 22). The object was to bring the level of the station platforms as close to the surface of the street as the height of the car itself would permit; in the case of Budapest the distance is about 9 feet. This principle of construction has since been followed in the construction of the Boston subway, of the Chemin de Fer Métropolitain in Paris, and of the New York underground railway. The Paris line is built with the standard gauge of 4 feet $8\frac{1}{2}$ inches, but its tunnels are designedly made of such a small cross-section that ordinary main line stock cannot pass through them. The system, so far as authorized in 1902, has a total mileage of 38·86 miles, of which seven-tenths are to be in tunnel and the remainder in open cutting or on viaduct. The lines complete and in operation in September 1902 had a mileage of 8·67 miles, and ran between the Porte de Vincennes and the Porte Maillot, between the Place de l'Étoile and the Porte Dauphine, and between the Place de l'Étoile and the Trocadéro. Each of these sections is self-contained and is worked independently, thus abolishing junctions, with their inevitable signal delays; even the northern loop, under construction in 1902, which will form a complete circle with the existing Porte de Vincennes–Porte Maillot line, is not to be worked as a closed circuit, but on the "shuttle" system as an independent line. The stations are very numerous—for example, there are eighteen on the Porte de Vincennes–Porte Maillot line, which is 6·6 miles long—and the average speed is about 13 miles an hour. The terminal stations are constructed as loops, thus enabling trains to pass from the up to the down line without shunting delays, and exchange stations are provided wherever the lines touch each other or other railways. On the main line a three-minute service is maintained by day (5.30 A.M. to

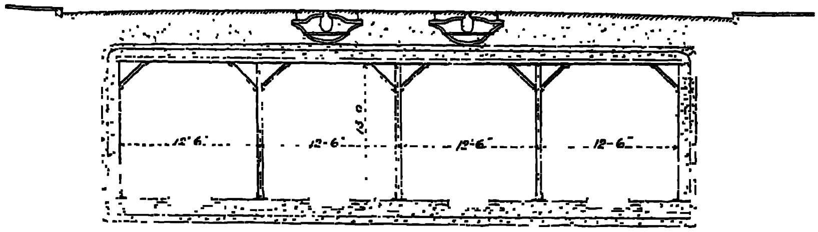

FIG. 23.—New York Rapid Transit Railway, showing also the tracks and conduits of the electric surface tramway.

8.30 P.M.) and a six-minute one by night (8.30 P.M. to 1 A.M.). The motive power is electricity, continuous current at 500 volts being employed. The New York underground railway (Fig. 23), when completed, will mark a still further step in advance, in that there are practically two different railways in the same structure. One pair of tracks is to be used for a local service with stations about one-quarter of a mile apart, following the general plan of operation in vogue on all other intra-urban railways. The other, or central, pair of tracks is for trains making stops at longer distances. Thus there is a differentiation between the long-distance traveller who desires to be carried from one extreme of the city to the other, and the short-distance traveller who is going between points at a much less distance.

To sum up, there are of intra-urban railways two distinct classes: the elevated and the underground. The elevated is used where the traffic is so light as not to warrant the expensive underground construction, or where the construction of an elevated line is of no serious detriment to the adjoining property. The underground is used where the congestion of traffic is so great as to demand a railway almost regardless of cost, and where the conditions of surface traffic or of adjoining property are such as to require that the railway shall not obstruct or occupy any ground above the surface.

Underground railways are of three general types: The one of extreme depth, built by tunnelling methods, usually with the shield and without regard to the surface topography, where the stations are put at such depth as to require lifts to carry the passengers from the station platform to the street level. This type has the advantage of economy in first construction, there being the minimum amount of material to be excavated, and no interference during construction with street traffic or subsurface structures; it has, however, the disadvantage of the cost of operation

of lifts at the stations. The other extreme type is the shallow construction, where the railway is brought to the minimum distance below the street level. This system has the advantage of the greatest convenience in operation, no lifts being required, since the distance from the street surface to the station platform is about 12 to 15 feet; it has the disadvantages, however, of necessitating the tearing up of the street surface during construction, and the readjustment of sewer, water, gas, and electric mains and other subsurface structures, and of having the gradients partially dependent on the surface topography. The third type is the intermediate one between those two, followed by the Metropolitan and Metropolitan District railways, in London, where the railway has an arched roof, built usually at a sufficient distance below the surface of the street to permit the other subsurface structures to lie in the ground above the crown of the arch, and where the station platforms are from 20 to 30 feet beneath the surface of the street—a depth not sufficient to warrant the introduction of lifts, but enough to be inconvenient.

Operation.

In the operation of intra-urban railways, steam locomotives, cables, and electricity have severally been tried, the first being used in the earlier examples of underground lines and in the various elevated systems in the United States. The fouling of the air that results from the steam-engine, owing to the production of carbonic acid gas and of sulphurous fumes and aqueous vapour, is well known, and its use is now practically abandoned for underground working. The cable is slow; and unless development along new lines of compressed air or some sort of chemical engine takes place, electricity will monopolize the field. Electricity is applied through a separate locomotive attached to the head of the train, or through motor carriages attached either at one end or at both ends of the train, or by putting a motor on every axle and so utilizing the whole weight of the train for traction, all the motors being under a single control at the head of the train, or at any point of the train for emergency. The distance between stations on intra-urban railways is governed by the density of local traffic and the speed desired to be maintained. As a general rule the interval varies from one-quarter to one-half mile, except on the express lines of the New York underground railway, where the inter-station interval averages about one and one-half miles. On the steam-worked lines the speed of trains is about 11 to 15 miles per hour, according to the distance between stations. Later practice takes advantage of the great increase in power that can be temporarily developed by electric motors during the period of acceleration; this, in proportion to the weight of the train to be hauled, gives results much in advance of those obtained on ordinary steam railways. Since high average speed on a line with frequent stops depends largely on rapidity of acceleration, the tendency in modern equipment is to secure as great an output of power as possible during the accelerating period, with corresponding increase in weight available for adhesion. With a steam locomotive all the power is concentrated in one machine, and therefore the weight on the drivers available for adhesion is limited. With electricity, power can be applied to as many axles in the train as desired, and so the whole weight of the train, with its load, may be utilized if necessary. On the Central London Railway the acceleration of gravity is also utilized; the different stations stand, as it were, on the top of a hill, so that outgoing trains are aided at the start by having a slope to run down, while incoming ones are checked by the rising gradient they encounter.

The following table (No. XX.) gives the statistics of the most recent English and American electric practice, the effort of the machines being actual output as measured by mechanical horse-power:—

TABLE XX.—*English and American Practice.*

	Central London.	Boston Elevated.	Manhattan Elevated. Electricity.	Manhattan Elevated. Steam.
Weight of train—tons (=2240 lb)	160¾	131	128½	110¾
,, ,, motor—,, ,,	42	27	34	21½
Weight of motor on drivers—tons	42	16	34	14
Number of motors . . .	1	5	2	1
,, ,, cars	8	5	6	5
Average distance between stops—feet	2550	2587	1775	1775
Schedule speed—miles per hour .	14·8	17·2	13·6	11·5
Maximum horse-power during acceleration	650	1600	950	250
Horse-power at full speed . .	220	200	160	150

On the Central London each train is worked by a single electric locomotive, though, owing to complaints of vibration from householders above the line, a modification of this arrangement is to be adopted; the Manhattan Elevated contemplates two motor cars, one at each end of the train, all the axles of each being equipped with motors; while the Boston Elevated, in order to overcome heavy gradients (8 per cent.), has one truck of every car supplied with power.

Cost.

The cost of intra-urban railways depends not only on the type of construction, but more especially upon local conditions, such as the nature of the soil, the presence of subsurface structures, like sewers, water and gas mains, electric conduits, &c.; the necessity of permanent underpinning or temporary supporting of house foundations, the cost of acquiring land passed under or over when street lines are not followed, and, in the case of elevated railways, the cost of acquiring easements of light, air, and access, which the courts have held are vested in the abutting property. The cost of building an ordinary two track elevated railway according to American practice varies from $300,000 to $400,000 per mile, exclusive of equipment, terminals, or land damages. The cost of constructing the deep tubular tunnel in London, whose diameter is about 15 feet, exclusive, in like manner, of equipment, terminals, or land damages, is about £170,000 to £200,000 per mile. The cost of the Metropolitan and Metropolitan District railways of London varied greatly on account of the variations in construction. The most difficult section, namely, that under Cannon Street, where the abutting buildings had to be underpinned, and a very dense traffic maintained during construction, while a network of sewers and mains was readjusted, cost at the rate of about £1,000,000 per mile. The contract price of the New York underground railway, exclusive of the incidentals above mentioned, was $35,000,000 for 21 miles, of which 16 miles are underground and 5 are elevated. The most difficult portion of the road, 4½ miles of four-track line, cost $15,000,000.

The burden of traffic on intra-urban railways assumes proportions not met on any trunk-line railways. During a year the Metropolitan and Metropolitan District railways of London, on a combined trackage of something more than 100 miles, handled upwards of 150,000,000 passengers; but a portion of the mileage of both these lines cannot be strictly reckoned as intra-urban. The elevated system in New York, with 40 miles of double track, has carried in a year over 221,000,000 passengers, and in a single day more than 1,000,000 passengers. The Central London Railway,

with a total of 5¾ miles of double track, has carried as many as 228,961 passengers in one day (29th October 1900, the date of the return of the City Imperial Volunteers from South Africa), and its total for the year 1901 was 41,188,389. (W. B. P.)

TRAMWAYS.

The commercial development of tramways, or as they are called in the United States of America, street railways, has become wholly a matter of mechanical traction. Since the introduction of the cable and electric methods, with notable economies and advantages, very few stage-coach or horse-tramway lines have been established; and the abandonment of the cable itself for electricity on all ordinary levels was in progress at the end of last century. After a long period of experimentation, neither storage batteries nor compressed-air systems can be said to have demonstrated their commercial advantages sufficiently to ensure their wide use. Few storage battery cars were to be found in operation in 1900; and in Berlin the municipality had so far acknowledged their comparative failure as to grant larger privileges to the trolley in the streets of that city, from which it had previously been barred. In Paris and New York compressed-air cars were operated on a few routes, but not in increasing numbers or with any apparent economy. The beginning of the 20th century saw electricity everywhere the dominating motive power in urban traction: for underground lines, with a third rail; for elevated lines, with a third rail; on streets and roads, whether city or surburban, with either the overhead trolley or the conduit system. Where the objection has still remained in cities to laying tracks through fine residential streets, a revival of earlier omnibus services has been attempted in the use of automobiles, propelled chiefly by electric motors and storage batteries. These cannot compete commercially with tramways, though they may be thought by some to be a desirable addition. Several cities in Europe and America have such lines in operation, and that in the city of Mexico may be mentioned as typical.

It is to the United States, with its new centres of busy population undergoing rapid development, that we must look for the most impressive figures of the tramway industry. The large areas covered, the great width of the streets, and the rectangular disposition of all the main thoroughfares have been favourable factors in stimulating a growth of remarkable proportions. In 1899 the number of cable cars declined from 4701 to 4250, and of horse cars from 3106 to 1489; but the number of electric cars increased from 46,549 to 50,658, and the track increased from 15,942 miles to 17,969. All told, there were 871 tramways of various types with a total of 19,213 miles of track and 58,736 cars. These represented a capital stock of $1,023,819,987 and a funded debt of $777,862,571, making a total of 1,801,682,558, or an increase of nearly $200,000,000 over the preceding year. The capitalization is at the rate of about $94,000 per mile of single track. There are no available statistics as to the return to capital from investment in tramways in America, but a study of the situation in 1897 went to show that they were then earning gross $150,000,000. In 1898 some 220 lines earned $130,000,000, these being large systems. The gain in gross earnings in 1898 over 1897 would doubtless reach $25,000,000, making $175,000,000 in 1898, when the total capitalization was about $1,622,000,000. If the net receipts be taken at 40 per cent., there remained applicable to bonds and stock from $60,000,000 to $70,000,000, or from 4 to 5 per cent. upon the entire capitalization as it stood, without regard to the proportion that may have been issued as a stock bonus with the bonds, or the newer construction not yet on an earning basis.

The economies wrought by the introduction of mechanical traction on tramways are noteworthy. They are best evidenced by the analysis of some one system, and that which is available in the fullest detail is furnished by the Metropolitan Street Railway Company of New York, which has the largest composite system in the world, and is operating with animal, cable, electric, and other powers. This company ran 45,390,318 car miles in the year ending 30th June 1900. The cost of operating with the cable per car mile was 17·76 cents; with electricity, 13·16 cents; and with horses, 18·98 cents. The total passenger receipts were $14,335,406. Had the horse mileage been operated electrically, there would have been an economy of $540,000 in the change. Had the whole system been operated by horses, the cost would have been $8,615,082 instead of the actual $7,034,033, showing that on this one system mechanical traction had already effected an annual saving with its present traffic of over $1,500,000. The item of the 13·16 cents cost of operation per electrical car mile of the system is made up as follows: maintenance of way, 0·81; maintenance of equipment, 1·41; power, 1·99; transportation, 7·29; general expenses, 1·66. The percentage of operating expenses to gross receipts was as follows: cable, 51; electricity, 40·5; horses, 73·6. It is to be borne in mind that the Metropolitan electric system is regarded as the costliest of its class, namely, the underground trolley making contact with the feeding conductors by means of a "plough" lowered into a slotted conduit.

Mr J. Clifton Robinson, managing director and engineer of the London United Tramways, supplies the following particulars for the lines in West London owned by that company, which in 1901 were converted from horse to electric traction (overhead trolley), the mileage at the same time being doubled:—The cost of operation per car mile was, with horses, 9·00d.; with electricity it is 5·40d., made up of maintenance of way 0·75d., maintenance of equipment 1·02d., power 0·46d., and other expenses 3·17d. The average number of passengers carried per car mile was, with the horse cars, 8·14; with electric cars it is 11·00; and in addition to this increase in the number of passengers per car mile the mileage has increased over 300 per cent. With horse traction, 8 miles of route carried 9,000,000 of passengers per annum; with electric traction, 16 miles carried 32,000,000. The percentage of operating expenses to gross receipts was 82·00 per cent. with horses; with electricity it fell to 52·00 per cent., and it is expected that this figure will be improved upon when the plant in the power station is employed to the full capacity for which it is designed. In 1902 over 60 miles of line were authorized and in course of construction, and a total of not less than 100 miles is projected in West London and the Thames Valley.

The statistics as to the street railway earnings in America are based upon the universal practice there of charging a "flat" 5 cent fare for the whole trip, which may be 15 or 20 miles long, and often includes one or two free transfers. The extent of this "transfer" practice, which is not at all a familiar condition in Europe, may be inferred from the fact that in Kansas City, Mo., there are no fewer than 85 points of intersection on the leading tramway system, at each of which transfers are given out, so that any part of the city can be reached from any other part on one fare. The population of the urban district is only 215,000, but no fewer than 70,000 such transfers are issued daily. In Europe the measured tariff system prevails, so that while the short-distance rider for less than a mile pays one-fifth the American fare, the long-distance rider may pay two or three times as much. Curiously enough, the gross receipts per mile in Europe are quite as high as in America, indicating that European tramways lie in areas of dense population, while in the United States long cheap rides to reach homes in the suburbs are common. In fact, the rapid building up of suburbs round the American cities has been one of the most obvious results of tramway development; but it has not as yet become so pronounced in Europe as to excite comment. The general effect on American suburban real estate of the discrimination in favour of the citizen seeking a suburban home may be fairly judged from the experience of Brookline, Mass. From 1855 to 1885 the value of real estate had risen about $350,000 a year, reaching $17,000,000. In 1890, consequent on the introduction of the electric tramway and the rush of home-seekers to get out of Boston, the valuation jumped to $30,000,000, although property in the old centre was not injured.

A feature of commercial economy which does not appear at first sight in a study of the American figures is the ability to handle more passengers with fewer cars and fewer men. In the United States in 1890 there were 32,505 cars and 70,764 employés to 8783 miles of road. The electrical transformation was then getting into full swing, and 16-foot cars were in general use, the speed rarely exceeding 6 to 8 miles an hour. The average speed of the electric cars may now be put at 10 miles per hour, and the length of the car at 24 feet. The number of horse and electric cars has been reversed in the ten years. The total number of passengers carried in 1890 by all methods of power was 2,023,010,202, while for the year closing in 1900 the traffic for the electric cars alone is estimated at 4,000,000,000. On the latter basis, and estimating the daily car miles at 3,000,000, the daily saving to the tramways is $180,000. With the same mileage of track as in 1899, the New York Metropolitan showed a gain in 1900 of $1,562,920 in the gross and $695,896 in the net. On one line in New York with horse cars in 1897, the round trip occupied three hours, and 200 cars carried 17,000,000 passengers. With electric cars in 1900, the round trip required only two hours, and

300 cars carried 50,000,000 passengers. The value of the daily saving in time by the trolley to the American working population alone is over $20,000 per day.

The following table (No. XXI.) gives some idea of the relative growth of the development of electric tramways in the leading countries of Europe:—

																4052	142,150	9683

If to these figures there be added those of Norway and Sweden, Russia, Holland, Portugal, Rumania, Servia, and Bosnia, it would appear that for the last year under report there were in Europe 5092 miles of track, 147,760 kilowatt capacity of power plant, and 10,030 motor cars. The growth indicated by these figures did not slacken during 1900, when such cities as Paris and Geneva enjoyed the addition of extensive electric tramway systems; the former city, like London, also seeing a large underground electric railway system put in operation. It has been estimated that the entire Continental tramway enterprise represents an investment of probably £200,000,000. In Great Britain, according to Garcke's *Manual of Electrical Undertakings*, in 1901–1902 a total capital of nearly 40 millions sterling (ordinary, preference, and loan and debenture) was divided among 125 electric traction undertakings, and 47 municipalities had expended on electric traction an amount of 10½ millions. On 1st January 1900 British companies had been organized to build and operate foreign tramways with an authorized capital of £18,543,517, and towards this there had been paid in £9,854,372 for shares and £2,793,777 debentures, a total of roughly two-thirds the amount. To this, again, must be added £4,000,000 of British capital in Continental tramways; £2,000,000 in tramways in the colonies, but not of British corporate domicile; and £6,700,000 invested in American and Canadian tramway work. It should be added, however, that Continental capital, notably German, has of late been very active in the exploitation of tramway enterprises outside the respective territorial limits of the banking groups interested; while a more recent feature of such international financing has been the endeavour to purchase London underground electric railway franchises and companies by American capital. While much of this work may be due to a desire to create markets for apparatus, as well as to bring new securities into existence, it seems to be a fact that no city in the world has yet transportation facilities adequate to the demands of its own resident and suburban population, and this is specially the case in London.

For some of the British systems a large quantity of American apparatus has been imported; but British machinery and detail parts of excellent construction and durability are now freely obtainable, large factories for its production having sprung up in different parts of the country. The figures for 1898–99 of the British tramway system show the following results:—

Total number of cars	6,323
,, ,, locomotives (including motor cars)	584
,, ,, horses	44,171
,, ,, passengers carried	924,820,247
,, ,, car miles run	96,078,503
Gross receipts	£4,879,602
,, per car mile	1s. 0·192d.
Operating expenses	£3,675,559
,, ,, per car mile	9·12d.
Net receipts	£1,204,043
,, per car mile	3·072d.

Since these official figures were compiled, however, the advance of electric traction has been so rapid as to change many of them appreciably. For example, Dublin reported a cost per car mile of only 5·24d., and Leeds reported 5·97d. per car mile with a percentage of 47·3 for operating expenses, although its electric system was far from complete. According to Garcke's *Manual* for 1901–1902, of electrical tramways and light railways in the United Kingdom, the track mileage constructed was 1252 miles, under construction 846 miles, and authorized and about to be constructed 1348 miles, a grand total of 3446 miles. The number of electrical cars constructed was 3834, and under construction 777.

The sociological side of the electric tramway has many interesting aspects, some of which have important commercial or industrial features. In many cities the conversion of the old horse-car stables into electric centres has enhanced the value of adjoining real estate materially; while medical officers have noted a diminution of diseases that might be attributed to horses. The creation of new suburbs has been mentioned already. Another striking fact has been the deliberate effort manifested by tramway managers to reach parks and places of rural pleasure resort; in the United States over 100 tramways have reported as to their ownership of parks, and some of them have gone so far as to organize vaudeville entertainments, the performers during the summer travelling from place to place, and thus providing a constantly new programme. In Geneva, Switzerland, electric tramways have been developed with special reference to the parks on the outskirts; and one of the electric lines runs several thousand feet up Mont Salève, from the plateau of which an unsurpassed view is obtained of the Lake of Geneva on the left and the whole Mont Blanc range on the right.

(T. C. M.)

LIGHT RAILWAYS.

Great Britain.

The term light railways is somewhat vague and indefinite, and therefore to give a precise definition of its significance is not an easy matter. No adequate definition is to be found even in the British statute-book; for although Parliament has on different occasions passed Acts dealing with such railways both in Great Britain and Ireland, it has not inserted in any of them a clear and sufficient statement of what it intends shall be understood by the term, as distinguished from an ordinary railway. Since the passing of the Light Railways Act of 1896, it is possible to give a formal definition by saying that a light railway is one constructed under the provisions of that Act; but it must be noted that the Commissioners appointed under that Act have authorized many lines which in their physical characteristics are indistinguishable from street tramways constructed under the Tramways Act, and to these the term light railways would certainly not be applied in ordinary parlance. Still they do differ from ordinary tramways in the important fact that the procedure by which they have been authorized is simpler and cheaper than the methods by which special private Acts of Parliament have to be obtained for tramway projects. Economy in capital outlay and cheapness in construction is indeed the characteristic generally associated with light railways by the public, and implicitly attached to them by Parliament in the Act of 1896, and any simplifications of the engineering or mechanical features they may exhibit compared with the standard railways of the country are mainly, if not entirely, due to the desire to keep down their expenses.

The saving of cost is effected in two ways: (1) Instead of having to incur the expenses of a protracted inquiry before Parliament, the promoters of a light railway under the Act of 1896 make an application to the Light Railway Commissioners, who then hold a local inquiry, to obtain evidence of the usefulness of the proposed railway, and to hear objections to it, and, if they are satisfied, settle the draft order and hand it over to the Board of Trade for confirmation. The Board may reject the order if it thinks the scheme to be of such magnitude or importance that it ought to come under the direct consideration of Parliament, or it may modify it in certain respects, or it may remit it to the Commissioners for further inquiry. But once the order is confirmed by the Board, with or without modifications, it has effect as if it had been enacted by Parliament, and it cannot afterwards be upset on the ground of any alleged irregularity in the proceedings. (2) The second source of economy is to be sought in the reduced cost of actually making the line and of working it when made. Thus the gauge may be narrow, the line single, the rails lighter than those used in standard practice, while deep cuttings and high embankments may be avoided by permitting the curves to be sharper and the gradients steeper: such points conduce to cheapness of construction. Again, low speeds, light stock, less stringent requirements as to continuous brakes, signals, block-working and interlocking, road-crossings, stations, &c., tend to cheapness in working. On the lines actually authorized by the Board of Trade under the 1896 Act the maximum speed permitted has in no case exceeded 25 miles an hour, and that only on the level and in the straight. For such lines the normal minimum radius of the curves has been fixed at about 600 feet; when a still smaller radius has been necessary, the speed has been reduced to 10 miles an hour and a guard-rail insisted on inside the curve. Again, the speed has been restricted to 20 miles an hour on long inclines with gradients steeper than 1 in 50, and also on a line which had scarcely any straight portions and in which there were many curves of 600 feet radius and gradients of 1 in 50. In the case of a line of 2½ feet gauge, with a ruling gradient of 1 in 40, a maximum speed of 15 miles an hour and a minimum radius of curve of 300 feet have been prescribed. Curves of still smaller radius have entailed a maximum speed of 10 miles an hour. It must be understood that a railway described as "light" is not necessarily built of narrower gauge than the standard. Many lines, indeed, have been designed on the normal 4 feet 8½ inches gauge, and laid with rails weighing from 50 to 70 ℔ per yard; a flat-footed 60 ℔ rail, with the axle load limited to 14 tons, has the advantage for such lines that it permits the employment of a proportion of the locomotives used on main lines. The orders actually granted have allowed 50 ℔, 56 ℔, 60 ℔, and 70 ℔ rails, with corresponding axle loads of 10, 12, 14, and 16 tons. On a line of 2 feet gauge, rails of 40 ℔ have been sanctioned. In regard to fencing and precautions at level-crossings, less rigid requirements may be enforced than with standard railways; and in some cases where trains are likely to be few, it has been provided that the normal position of the gates at crossings shall be across the line. Again, if the speed is low and the trains infrequent, the signalling arrangements may be of a very simple and inexpensive kind, or even dispensed with altogether.

Table XXII. gives particulars of the applications which had been made up to the end of 1901 to the Commissioners since the passing of the Act in 1896. It should be mentioned that the Act, which in 1902 was re-enacted for a further term, provided that the Treasury might advance a portion of the money required for a line in cases where the council of any county, borough, or district had

[4] Five amending orders. [5] Three amending orders. [6] One scheme (Derby and Nottingham) applied for 14 miles of 4′ 8½″ and 5¼ of 3′ 6″.
[7] Nineteen amending orders. [8] Including one of 39¾ miles steam or electric.

agreed to do the same, and might also make a special advance in aid of a light railway which was certified by the Board of Agriculture to be beneficial to agriculture in any cultivated district, or by the Board of Trade to furnish a means of communication between a fishing-harbour and a market in a district where it would not be constructed without special assistance from the State.

As a general classification (Table XXIII.), the Commissioners have divided the schemes that have come before them into three classes: (A) those which like ordinary railways take their own line across country; (B) those in connexion with which it is proposed to use the public roads conjointly with the ordinary road traffic; and (Neutral) which includes inclined railways worked with a rope, and lines which possess the conditions of A and B in about equal proportions.

The so-called light railways in the United States and the British colonies have been made under the conditions peculiar to new countries. Their primary object being the development and peopling of the land, they have naturally been made as cheaply as possible; and as in such cases the cost of the land is inconsiderable, economy has been sought

by the use of lighter and rougher permanent way, plant, rolling stock, &c. Such railways are not "light" in the technical sense of having been made under enactments intended to secure permanent lowness of cost as compared with standard lines. On the Continent of Europe many countries have encouraged railways which are light in that sense. France began to move in this direction in 1865, and has formulated elaborate provisions for their construction and regulation. Italy did the same in its laws of 1873, 1879, 1881, 1887, and 1889; and Germany fostered enterprise of this kind by the Imperial edicts of 1875, 1878, and 1892. Holland, Hungary, and Switzerland were all early in the field; and Belgium has succeeded, through the instrumentality of the semi-official Société Nationale de Chemins de Fer Vicinaux, started in 1885, in developing one of the most complete systems of rural railway transport in the world. An account of the regulations prescribed by several of these countries is given below.

France. In France the lines which best correspond to British light railways are called "*Chemins de fer d'interêt local.*" These are regulated by a decree No. 11,264 of 6th August 1881, which the Ministry of Public Works is charged to carry out. Construction can be commenced after the *Conseil General* of the department has approved the project, and the Prefect the details; only if the scheme interferes with rivers or great public lines of communication does the Ministry of Public Works interfere. The model "form of regulation" lays down the scales of the drawings and the information to be shown thereon. For the first installation a single line is prescribed, but the "concessionaire" must provide space and be prepared to double when required. The gauge may be either 1·44 metres (4′ 8·7″), or 1 metre (3′ 3·37″), or ·75 centimetres (2′ 5·5″). The radius of curves for the 1·44 gauge must not be less than 250 metres, 100 metres for the 1 m. gauge, and 50 metres for the ·75 m. gauge. A straight length of not less than 60 metres for the largest gauge, and 40 metres for the smallest, must be made between two curves having opposite directions. Except in special cases, gradients must not exceed 8 in 100; and between gradients in the opposite sense there must be not less than 60 metres of level for 1·44, and 40 metres for 1 m. and ·75 m. gauges. The position of stations and stopping-places is regulated by the Council of the Department. The undertaking, once approved, is regarded as a work of public utility, and the undertakers are invested with all the rights that a public department would have in the case of the carrying out of public works, and are subject to the same responsibilities and conditions. Within the areas that come under the "Defence Acts" the works are subject to all the military necessities and laws which are prescribed for works in such areas, both retrospectively and prospectively.

The Prefecture is responsible for preventing and limiting all interference by the undertakers with public and private rights, and for regulating the precautions for public safety. The contracts for the work are made either under public competition, on the published price list approved and in use in the department, or by sealed tenders from a selected list of contractors. The working of the lines is under detailed regulations, to which the approval of the Prefect of the department must be obtained; and the penalty for non-observance of these is practically confiscation, if defalcation, or neglect, is carried far enough. The Prefect may step in and work the line at the expense of the "concessionaires." The matters as regards which the Prefect must be consulted and satisfied are: numbers of staff in respect to safe working; efficiency, design, and construction of the locomotives and of the rolling stock; classification and interior arrangements of the passenger and goods carriages: separation of sexes; size and composition of trains; number of trains; policing; general bye-laws; maximum and minimum speed; and time-tables. At the end of the period of the concession the "département" comes into possession of the road and all its fixed appurtenances, and in the last five years of the period the "département" has the right to enter into possession of the line, and apply the revenue to putting it into a thorough state of repair, if it has been allowed to deteriorate. It has also the right to select and buy, at a price to be adjudged by experts, any part or all of the rolling stock and movables, and the owners can only oblige it to take the fuel and stock of necessary working and maintenance materials at a valuation. It has also the right to purchase the undertaking at the end of the first fifteen years, the net profits of the preceding seven years to govern the calculation of the purchase price. The maximum 1st, 2nd, and 3rd class passenger fares are, per kilometre, ·067 f. (·6d.), ·050 f. (·455d.), and ·037 f. (·34d.) respectively, when the trains are run at "*grande vitesse,*" the fares including 30 kilogrammes weight of personal baggage. All goods trains are at *petite vitesse* fares, except those for oysters, fish, and perishable goods. Any reduction of rates must be subject to the approval of the Prefect and of the Minister of Public Works. All preference rates, except on behalf of the public service, are interdicted. All the details of tickets, way bills, invoices, and papers in connexion with traffic, delivery, and storage are specified, and the working hours prescribed by the Prefect.

Belgium. In Belgium a public company under Government control does all that in France forms the responsibility of the Ministry of the Interior and of the Prefect of the department. Over an average of years it appears that 27 per cent. of the capital cost was found by the State, 28 per cent. by the province, 40·9 per cent. by the communes, and 4·1 per cent. by private individuals. As far as possible, these railways are laid beside roads, in preference to independent formation; the permanent way costs £977 per mile in the former as against £793 in the latter. If laid in paving, the price varies between £1108 and £2266 per mile. The total length in Belgium, either worked by the company or leased by it, is 726$\frac{1}{2}$ miles. To work this mileage, 253 locomotives, between 18 and 30 tons in weight, 716 passenger vehicles, 400 covered vans, 1367 open waggons, and 10 special vehicles are in constant use. In the case of a Belgian light railway intended primarily to serve an agricultural district, about 12$\frac{1}{4}$ miles in length, and mainly dependent upon its goods traffic, the line is constructed on the road, excepting where steep gradients, &c., make slight diversions desirable. Usually a line of way is formed at one side of the road, raised slightly by ballast, &c., and separated from the remainder of the road by kerbstones; it resembles a footpath alongside a country road. In this way the railway is not available for ordinary carriage traffic, nor is it used by pedestrians. Through villages, and where roads have to be crossed, the line is of the usual tramway type. The line is of 1 metre gauge, with steel rails weighing 21$\frac{1}{2}$ kilos (42 lb) per yard. In the towns a deeper rail is used, weighing about 60 lb per yard. In three lines of the Vicinaux system, in the aggregate 45 miles in length, the sharpest curves are 30 metres, 35 metres, and 40 metres respectively. There are gradients of 1 in 20 and 1 in 25. The speed is limited, by regulation, to 30 kilometres (about 18 miles) in the country and 8 miles per hour in towns and through villages; the time allowed in the time-table for the journey, for instance, from Andenne to Eghozee, 12$\frac{1}{4}$ miles, averages one hour twenty-five minutes, but one train in the day each way only takes about one hour five minutes. The engine, 18 tons weight, has six wheels coupled, each of 3 feet diameter; all moving parts are cased, and it is driven from either end (the driver, of course, always being in front).

A train, for example, at starting, is composed of one goods waggon, one passenger carriage, and one fourgon or luggage van. For suburban passenger traffic there is usually no van, but the Société has a certain number of vehicles forming a second-class compartment and a small van. Vans have a post office letter-box, in which letters can be posted at the various halting-places.

A room in an inn generally forms a waiting-room for passengers, and a place where parcels can be left, either until called for or to be picked up by the train. No tickets are, however, issued, or ordinary station business transacted; and it is not usual to make any payment to the proprietor of the inn, who gladly affords these slight facilities in return for the custom brought to the house. In addition to the stations as above, there are also fixed points (with a notice-board only) where the train stops if there is any one to pick up or set down, such as at important cross-roads, &c.

In Italy many railways which otherwise fulfil the conditions of a light railway are constructed with a gauge of 4′ 8$\frac{1}{2}$″. The weights are governed by what the railway has to carry and the speed. Light locomotives, light rails, and light rolling stock are employed.

There are no bridges, except where watercourses occur. Cuttings are reduced to a minimum; and where the roads are sufficiently wide, the rails are laid on the margins. The advantage of uniformity of gauge is in the use of trucks for goods which belong to the rolling stock of the main lines.

Italy. In Italy these railways are called "Economic Railways," and are divided into five types. Types I., II., and III., are of 4′ 8½″ gauge, type IV. of 0·95 m., and type V. of 0·70 m.; but as there is no example of type V., the classification is practically one of 1·445 m. (4′ 8½″) and one of 0·95 (3′ 0·5″). The chief difference between the first three types lies in the weight of rails and rolling stock and in the radius of the curves. The real light railway of Italy is that of type IV.: gauge, 0·95 m. (3′ 0·5″); weight of rails, 12 (26·45 ℔) to 20 (44 ℔) kilos.; mean load per axle, 6 tons; minimum curve, 70 m. (229′ 2·6″) radius; width of formation, 3·50 m. (11′ 5·5″); top width of ballast, 2·10 m. (6′ 10·7″); depth of ballast under sleepers, 0·10 m. (3′ 9·5″); maximum gradients, 1 in 50; length of sleepers, 1·70 m. (5′ 6·92″); width between parapets and width of tunnels, 1 m. over width of carriage; height of tunnels, 5 m. (16′ 4·85″); locomotives, maximum weight per axle 6 tons, rigid wheel base 1·80 m. (5′ 10·86″), diameter of driving wheels 1 m. (3′ 3·37″).

Germany. In Germany the use of light railways (*Klein-bahnen*) has made great strides. The gauges in use vary considerably between 4′ 8½″, the standard national gauge, and 1′ 11¾″, which appears to be the smallest in use. They are under the control of the Post and Telegraph Department, the State issuing loans to encourage the undertakings; the authorities in the provinces and communes also give support in various ways, and under various conditions, to public bodies or private persons who desire to promote or embark in the industry. These conditions, as well as the degree of control over the construction and working of the lines, are left to the regulation of the provincial governments. Similarly, the same authorities decide for themselves the conditions under which the public roads may be used, and the precautions for public safety, all subject to the confirmation of the Imperial Government. For instance, at speeds of less than 27 miles an hour, a buffer compartment (instead of a buffer vehicle) may be sufficient between the passenger carriages and the engine; the conductor may have sole charge of the train, sell tickets at stopping-places where no ticket-office is maintained, and look after payments for luggage; the driver and stoker may be charged with the care of the carriages and the greasing of the wheels; women may be employed as gate-keepers; fencing need not be continuous; gates at level-crossings need not always be insisted on; telegraph and bell signals may be dispensed with; trains may occasionally stop at points intermediate to the usual stopping-places; trains of limited size (50 axles) may be pushed at low speeds; brakes per axle on the carriages—actually applied—may be reduced in proportion to the gradients. The freedom which the legislature in Germany has given to provincial and communal authorities to regulate these railways by rules growing out of experience and common sense, in contradistinction to the empirical State regulation which exists in other countries, has resulted in a very large and rapid adoption of their use to the development of rural industries of all kinds.

Portable railways. What are known as "portable railways" should be included in the same category as light railways. With a 24″ gauge, lines of a portable kind can be made very handily, and the cost is very much less than that of a permanently constructed light railway. The simplicity is great; they can be quickly mounted and dismounted; the correct gauge can be perfectly maintained; the sections of rails and sleepers (which are of iron) are very portable, and skilled labour is not required to lay or to take them up; the making of a "turn-out" is easy, by taking out a 15 foot section of the way and substituting a section with points and crossings. The safe load per wheel varies between 12 cwt. on a 10 inch 16 ℔ wheel, and 40 cwt. on an 18 inch 56 ℔ wheel. The rolling stock is constructed either for farm produce or heavy minerals, the latter holding 10 to 27 cubic feet. For timber, 4 or 5 feet bogies can be used. A useful waggon for agricultural transport on a 24-inch gauge line is 16 feet long by 5 feet wide; it weighs 72 cwt. and costs £30. A portable line of this kind will have 20 ℔ steel rails and 2112 steel sleepers—4′ 6″ long—to a mile, laid 2′ 6″ apart centre to centre. The total cost per mile of such a line, including all bolts, nuts, fish-plates, and fastenings, ready for laying, delivered in the United Kingdom, is under £500 a mile.

See EVANS AUSTIN. *The Light Railways Act*, 1896, which contains the rules of the Board of Trade.—W. H. COLE. *Light Railways at Home and Abroad.*—Lieut.-Col. ADDISON. Report to the Board of Trade (1894) on Light Railways in Belgium.

(C. E. W.)

MOUNTAIN RAILWAYS.

Railways having gradients above a certain limit, which may be taken as about 30 in 1000, are regarded as mountain railways. They are of three kinds: adhesion lines; rack railways, either pure rack or rack and adhesion combined; and cable railways.

Adhesion lines (Table XXIV.) may be either of normal or of narrow gauge. The maximum gradient is dependent on

climatic conditions, a dry climate being the most favourable. The theoretical limit is about 60 in 1000; between 50 and 60 in 1000 an adhesional engine is able to haul only its own weight. The gradient should not in practice exceed 45 in 1000; and even that is too heavy, for theoretical conditions cannot always be realized. A wet rail will prevent the use of the theoretical adhesion of the driving wheels, and the gradients must be such that a locomotive can haul some paying load in all states of the weather. On the Albula or Engadine railway in Grisons, Switzerland, the first intention was to lay out the line on a gradient of 45 in 1000; but after consultation with the leading engineers in Switzerland, a gradient of 35 in 1000 was chosen, on the ground of working economy.

Locomotives are of very varied types; but the tendency is towards those which have as much of their weight as possible on the driving wheels, so as to be available for adhesion, and which possess great lateral flexibility for passing round sharp curves. In vehicles, reduction of dead weight and lateral flexibility are usually aimed at. The best have long carriages on bogies; these, however, are more used in America than in Europe. The brakes are like those used on ordinary railways. On the mountain sections of the St Gothard the maximum speed is 45 km. an hour on a rising gradient of 1 in 39; on the Südost railway it is 25 km. an hour on one of 1 in 20; while on the Landquart Davos line it is 20 km. on one of 1 in 22.

Rack Railways.—For gradients above 40 in 1000 a rack railway is the more economical. Some railways which are mainly adhesional operate the steeper grades by means of a rack. When the incline is above 40 in 1000 for the major part of the distance, the rack alone is employed. Above 250 in 1000 the rack is impracticable, partly because the locomotive has to be made disproportionately heavy, and partly because of the danger that the cog-wheel will mount the rack. Since the construction of the Mount Washington and the Rigi lines, the number of rack railways has rapidly increased; and many systems have been introduced, the development of which is illustrated by the names of the early Blenkinsop rack, the Washington, the Riggenbach, the Abt, the Klose, the Pilatus, and the Strub. On the Abt rack, which has the unique advantage that several rack-plates can be placed parallel, the teeth break joint at $\frac{1}{2}$, $\frac{1}{3}$, or $\frac{1}{4}$ of their pitch, according to the number of rack-plates. The cog-wheels are therefore constantly in action with the rack, an arrangement which conduces to smooth working. The rack introduced by Colonel Locker on the Pilatus railway is peculiar in having its teeth placed horizontally, in consequence of the heavy gradients, the steepest of which is 480 in 1000. The Strub rack introduced on the Jungfrau railway is very simple; a rail of the ordinary Vignoles type is employed, the teeth being cut in its head, which is made correspondingly higher than usual (Table XXV.).

The permanent way has of late years mostly been made with steel rails and steel sleepers, bedded in ballast of coarse gravel. The rack is placed in the middle of the track, either fixed directly to the sleepers or elevated on chairs. As the space allowed for change of temperature must necessarily be kept as small as possible, the rack is composed of pieces 3 to 3·5 m. long. To prevent the permanent way from creeping downhill, stops are placed on the downside of the sleepers. Trains are transferred from one track to another either by means of sliding platforms or movable and fixed rack arrangements. On combined rack and adhesion lines the entrances to the rack sections are provided with a piece of rack placed in springs, to enable the pinions of the engine to pass on smoothly and without stoppage. Swiss engineers mostly prefer the Riggenbach rack, on account of its rigidity and

simplicity. The Abt rack has the advantage of smoother working, and is more frequently employed outside of Switzerland. On street railways and railways with numerous level-crossings the Riggenbach system is preferred, because it only breaks the road in one line, and the rack teeth are on a level with the street. For the Abt at least three lineal spaces must be kept clear.

In designing rack-rail locomotives the same rules hold as for ordinary locomotives. In the later rack lines adhesion is not utilized, the wheels being loose on the axles. Originally the boilers were placed vertically; but it was not long before the present plan was adopted of arranging them in such a way that their axis is about horizontal when the engine is on the average gradient of the line. The fire-box and grate should be of the largest possible dimensions. In the most recent practice big locomotives working with combined rack and adhesion have separate mechanical arrangements for the two, each driven by its own pair of cylinders. Engines are fitted both with air-brakes and with a brake to be applied by the driver or fireman, the action in each case being on the cog-wheel axle. The discharge of smoke is so great, owing to the heaviness of the gradients and the slow rate of progress, that it is not only a great nuisance but in the larger tunnels positively dangerous. As far as possible, therefore, tunnels are avoided, especially on the heavy gradients, and apparatus for ventilation and smoke-consumption has to be provided.

Of late years electric motors have been largely used. They were first employed on the Barmen mountain railway, which is fitted with the Riggenbach rack and has a maximum gradient of 185 in 1000. Other electrically-driven lines are the Mont Salève (250 in 1000), the Salgo Tarjan (140 in 1000), the Gornergrat (200 in 1000), and the Jungfrau (250 in 1000). The engines on the Gornergrat railway have two independent, asynchronous, three-phase, six-pole motors, with wound armatures (rotors) and slip-rings; these with a current of 40 periods per second make 800 revolutions a minute, and develop together 180 horse-power at that speed with 540 volts in the trolley wires. They are fixed on the frame of the engine, and drive the cog-wheel axles by means of 12 : 1 gearing. At the normal speed of 7 kilometres ($4\frac{1}{3}$ miles) an hour, the tractional force is about 6 tons, the weight of the locomotive being 10·6 tons. There are two distinct brakes. A hand-brake apparatus acts on the driving axles, and the motors are supplied with braking drums and straps, the latter being applied (1) by hand, (2) automatically when a certain speed is exceeded, (3) as soon as the electric current is from any cause interrupted. The last arrangement is worked by means of a solenoid. The most remarkable mountain railway is perhaps the Jungfrau, which is to be carried—almost entirely in tunnel—4093 metres above sea-level, or more than 1000 metres above the line of perpetual snow, amid glacial surroundings of the most magnificent character.

Vehicles differ according to the type of line. On mixed rack and adhesion lines they depart but little if at all from the ordinary style. On the steep gradient pleasure lines they are built as light as possible, the dead weight being in some cases reduced to 75 kilometres per passenger place. The wheels are loose on the axles. Passenger carriages contain 48 to 60 places, while the goods vans have a carrying capacity of 6 tons, with a dead weight of 2 to 5 tons. All the waggons are fitted with 1 or 2 cog-wheels for braking purposes. On the tourist railways with heavy gradients the speed is 5 to 7 kilometres an hour; in easier gradients 8 to 10 kilometres, and on well-constructed rack lines and combined rack and adhesion, 12 to 15 kilometres on the rack and about 18 kilometres on the adhesion sections. On the heavier inclines the locomotive, as a matter of safety, is always behind the train and not coupled to it.

On the pure rack railways the slowness of the speed renders it impossible to get big returns from the rolling stock; hence the working expenses per mile of line appear high. Maintenance also costs more than with an ordinary adhesion line. For rack railways the cost of construction varies between £3000 and £32,000 a kilometre, and is only slightly influenced by the particular rack system chosen, apart from the expenses of the rack mechanism on the permanent way and engines; other expenses are quite independent of the system adopted. At the end of 1897 the number of rack railways in the world was 71, with a total length of 887·8 kilometres; and of these, 32 were on the pure rack principle. Of the Locker, Bissinger, and Telfner systems there was one example of each, of the Klose 2, of the Abt 29, and of the Riggenbach 35.

Cable Railways (Table XXVI.).—There are two main systems of cable railway: (1) that in which a continuous cable is carried over two main drums at each end of the line, the motion being derived either (*a*) from the weight of the descending waggons, or (*b*) from a motor acting on one of the main drums; (2) that in which each end of the cable is attached to waggons, one set of which accordingly ascends as the other descends. The latter is the system ordinarily applied on mountain cable railways. The weight required to cause the downward motion is obtained either by means of material that has to be transported to the foot of the hill, or by water ballast; while to aid and regulate the motion generally, steam or electric motors are arranged to act on the main drums, round which the cable passes in sufficient turns to prevent slipping. When water ballast is employed, the water is filled into a tank in the bottom of the waggon; if passengers are carried, its quantity is regulated by the number ascending or descending.

In order to control the acting force and render the working of the line as easy as possible, the longitudinal section must be laid out according to certain fixed rules, which, if strict economy is aimed at, must also be observed in cases where the movement of the waggons is governed by water-power acting on the main turning drums. The alignment is perfectly straight, but curves are admissible when they improve the lie of the railway. The permanent way consists of two, three, or four rails, facility of crossing being the end aimed at when more than two are used. In the modern system, however, which admits of very good crossing arrangements, only two rails are employed. On the Stanzerhorn cable railway, Switzerland, both the outer rails are through rails; while the inner ones are provided with counter rails, to leave room for the passage of the cable, which is guided by the rollers below the track. The cars have four wheels keyed to the axles. On one side these have double flanges, whereas on the other they are very broad and without flanges. When the car reaches the siding, the double-flanged wheel keeps it to the through rail, so that it is taken automatically through the siding, while the other broad wheels pass smoothly over the points. Each metal of the double-railed line being a through-rail on the outer half of the sidings, the two cars on each division of the track have their double-flanged wheels on opposite sides. The rails weigh 16 to 30 kilos a metre. Both wooden and steel sleepers are used; on the heavier gradients they are generally bedded in masonry, and on the gentler in gravel anchored to firm supports, to prevent sliding. The gauge, as a rule, is one metre. The total weight of the permanent way varies from 100 to 200 kilos per metre. The cable, which weighs from 2 to 6 kilos per metre, is of such a size as to give a factor of safety of 8 to 10 on the maximum strain, and its end is so

fastened that an automatic brake is brought into play if it slips from its grip. Guiding rollers are placed between the rails at such intervals that the cable does not touch the ground when the tension is least. For braking purposes a special rail—frequently a rack, either Abt or Riggenbach—is generally employed; and where the gradient exceeds 250 in 1000 a catch has to be introduced, to prevent the braking cog-wheels from mounting the rack. Other devices are sometimes used; on the Stanzerhorn line, for example, there are brake jaws, which are screwed down on the tapered head of the brake rail. Various methods of applying the brakes are employed. As a rule, there is an automatic brake, brought into action by turning a weighted lever, and a screw brake, manipulated by the guard; sometimes also an automatic brake applies itself when the speed exceeds a certain maximum. The steepest gradient used is about 650 in 1000. The waggons have rarely more than two axles; and the passenger coaches, which hold 32 to 48 persons, weigh from 6 to 18 tons. The cost of construction varies from £10,000 to £30,000 per kilometre.

Construction.—Mountain railways are frequently exposed to the special dangers of the regions they traverse, such as falls of stone, violent and sudden outbursts of torrents carrying heavy masses of débris, avalanches, and slips of various kinds, all of which have to be guarded against. The extent of these dangers is determined by the more or less close proximity of the snow line, the topographical nature of the country, and the character of the soil; so it may happen that a railway may attain a very great elevation above sea-level and yet encounter only conditions that are comparatively, or even absolutely, easy.

Where falls of stone are to be feared, it is usually preferable to put the line in a tunnel or gallery. If it is to be in the open, the protective works consist of stone walls, with or without a backing of earth, or of heavy timber fences. In the case of torrents, the line is sometimes carried under their bed in a gallery; they are also guarded against by the systematic arrangement of their courses, or by the erection of cross-walls, which serve to arrest the velocity of the water and prevent débris from rushing down in too heavy masses. Avalanches are often avoided by means of tunnels or galleries; if these are too expensive or otherwise impracticable, the snow is held back by retaining walls or dams, or prevented from slipping by the friction of rows of poles, wattlework, or small stone-walls. To deal effectively with torrents, as well as avalanches, it is frequently necessary to carry the protective works to the highest regions of the mountains, where many of these dangers have their origin. (S. J. B.)

Raipur, a town and district of British India, in the Chhattisgarh division of the Central Provinces. The town is 994 feet above the sea, 188 miles east of Nagpur; railway station. Population (1881), 24,948; (1891), 23,759. There are ruins of an immense fort, with many tanks and old temples. Raipur is the cantonment for a wing of a Madras native infantry regiment. It has a German mission, four printing-presses, a Government high school, with 1014 pupils in 1896–97. The Rajkumar College, for the education of the sons of the chiefs of Chhattisgarh, was transferred here from Jubbulpore in 1894; there are 23 pupils, maintained by fees and an endowment.

The district of RAIPUR has an area of 11,724 square miles; population (1891), 1,584,427, showing an increase of 13 per cent., which had been continuous since 1872; (1901), 1,442,778, showing a decrease of 9 per cent., due to the results of famine. Land revenue, Rs.8,66,451, the incidence of assessment being under 4 annas per acre; cultivated area (1897–98), 2,382,308 acres, of which 40,422 were irrigated from tanks, &c.; number of police, 681; boys at school (1896–97), 15,384, being 13·2 per cent. of the male population of school-going age; registered death-rate (1897), 78·68 per thousand. The principal crop is rice. Manufactures of cotton goods and brass ware; steam cotton mill at Rajnandgaon, with 156 looms and 14,868 spindles, employing 800 hands. The north-west corner of the district is crossed by the main line of the Bengal-Nagpur Railway, and a branch tramway is now being constructed from Raipur town due south towards the state of Bastar. The district suffered severely from famine in 1896–97, and again in 1899–1900.

Rajahmundry, or RAJAMAHENDRI, a town of British India, in the Godavari district of Madras; on the left bank of the river Godavari, at the head of the delta, 367 miles north of Madras; a station on the East Coast Railway, which is here carried across the river by a bridge of twenty-one spans. Population (1881), 24,555; (1891), 28,397; municipal income (1897–98), Rs.38,840. The Government college, one of the four provincial schools established in 1854, had 88 students in 1896–97. There are also a training college and high school, two printing-presses, issuing one English and two vernacular newspapers; a public library and reading-room; and a teachers' association.

Rajendralala Mitra, Raja (1824–1891), Orientalist and author, was born in 1824 in a suburb of Calcutta, and died in that city on 26th July 1891. For half a century he was the life and soul of the Bengal Asiatic Society. Five years after his birth Dr H. H. Wilson proposed the admission of learned natives into the Society founded by Sir William Jones in 1784; and elected under this rule, Rajendralala Mitra filled successively the offices of librarian (1846), of vice-president (from 1861 onwards), and in 1885 of president of the Society. Of the Kayasth caste, descended from a family which had served with profit the Nawabs of Murshidabad, he devoted himself from childhood to the study of the classic languages of the East in his father's library. He owed none of his early education to British schools, although for a time he attended the Medical College and studied law. He held no public appointment except that of director of the studies of young zemindars, wards of Government. The distinction which he won, both in Europe and in Asia, for his ability, industry, and research was not the product of State-aided education, but of the spirit of inquiry infused into Indian society by the private efforts of such scholars and statesmen as Sir William Jones, Lord Teignmouth, Henry T. Colebrooke, Sir Charles Wilkins, Dr H. H. Wilson, and James Prinsep. The public service, and the professions of law and medicine, so attractive to Bengalis, seemed to Rajendralala only a distraction from the higher purposes of life opened to him by the Asiatic Society. As he wrote: "Neither Ganesa, the Hindu patron of wisdom, nor Saraswati, goddess of learning, seems ever to have paid any encouragement to history, and as a consequence Indian literature is almost void of all authentic historical records." He set himself to supply this deficiency, using the material supplied by poetry, fable, and tradition, and wresting from stone, brass, and pottery the secrets of the past. He brought to the task a rare knowledge of Sanskrit, Persian, and the classic languages of the East, and a power of writing pure English which few Europeans possess.

His principal work, published in 1875, *The Antiquities of Orissa*—described by him as "some relics of the past weeping over a lost civilization and extinguished grandeur"—is a storehouse of information on architecture, religion, and the social history of India. Three years later he published *Buddha Gaya*, the hermitage of Sakya Muni, containing the story of Buddha's penance, a learned discussion of chronology, and copious accounts of architectural remains, sculptures, and inscriptions. In the *Indo Aryans* he collected together many of his historical contributions to the Asiatic Society's *Journal*, and in the *Bibliotheca Indica* a large number of Sanskrit texts were supplied and explained by him. His catalogues, and his frequent papers published in the Bengal Asiatic Society's *Journals*, show the accuracy and wide range of his inquiry, and knowledge of religion, literature, philology, antiquities, and the manners and customs of India. Although he served as a member of the Calcutta municipality, he took little part in public affairs. Nevertheless, his influence upon modern Indian society was great; and inspired as he was by a fearless search after truth, he naturally came into conflict with the orthodox Hindus, who regarded any questioning of myths and traditions as both heresy and want of patriotism. The University of Calcutta made him a Fellow and Doctor of Law. Foreign societies enrolled him in their ranks, and his Sovereign conferred upon him the dignity of C.I.E. But the distinctions which he valued above all others were his election as president of the Bengal Asiatic Society, and the discovery of a key to the history of the past by diligent research into the relics which the ravages of time and climate were too quickly destroying. (W. L.-W.)

Rajgarh, a native state of Central India, in the Bhopal agency. Area, with the dependency of Sutalia, 655 square miles. Population (1881), 117,533; (1891), 119,489; average density, 182 persons per square mile. The estimated revenue is Rs.5,00,000 and the tribute to Sindhia, Rs.85,172. The chief, whose title is Rawat, is a Rajput of the Omat clan, claiming descent from Vikramaditiya. The grandfather of the present chief became a Mahommedan, but the family have now been received back into Hinduism. British currency has recently been adopted in the state. The town of RAJGARH, which is also called Biaora, has a population of (1881), 6881; (1891), 6476.

to cast upon him responsibility for the failure of Vatican policy towards France, and for the prevalence of reactionary tendencies during the later years of Leo XIII.'s pontificate, there is no evidence to show Cardinal Rampolla to have been more than a faithful exponent of ideas already formed, though not completely applied, before his appointment to the secretaryship of state.

Rampur, a stative state of India, in subordination to the North-Western Provinces. It lies in Rohilkhand, between the British districts of Moradabad and Pilibhit. Area, 945 square miles. Population (1891), 551,249; (1901), 532,067, showing a decrease of 3 per cent. Gross revenue, Rs.31,83,000; military force, 2556 men, including Imperial Service troops. The chief, whose title is Nawab, is a Rohilla Pathan, whose family have always been loyal to the British connexion. The state is crossed by a branch of the Oudh and Rohilkhand Railway from Bareilly to Moradabad. The town of RAMPUR is on the left bank of the river Kosila, 620 feet above the sea; railway station, 39 miles north-west of Bareilly. Population (1891), 76,733; (1901), 77,862. There are manufactures of damask and pottery.

Rampur Boalia, or BEULEAH, a town of British India, the administrative headquarters of Rajshahi district in Bengal; on the left bank of the Ganges. Population (1881), 19,228; (1891), 21,407. It was originally chosen as a commercial factory for the silk trade, which is again being officially encouraged by the Agricultural Department. The town contains a Government college, a collegiate high school, and an industrial school for sericulture; there are eight printing-presses, issuing two vernacular periodicals, a public library and debating club. Most of the public buildings were severely damaged by the earthquake of 12th June 1897. There is a regular steamer service with Damukdia Ghat, 50 miles south-east on the Eastern Bengal Railway.

Ramsay, Sir Andrew Crombie (1814–1891), British geologist, was born at Glasgow on 31st January 1814. Intended for commercial life, he was for a time actually engaged in business, but from spending his holidays in Arran he became interested in the study of the rocks of that island, and was thus led to acquire the rudiments of geology. A geological model of Arran, made by him on the scale of two inches to the mile, was exhibited at the meeting of the British Association at Glasgow in 1840, and attracted the notice of Murchison, with the result that he invited its maker to accompany him on a geological expedition to America. Ramsay accepted the offer, but the arrangement subsequently fell through, and instead he received, by Murchison's good offices, an appointment on the Geological Survey, on which he served for forty years, from 1841 to 1881. He was first stationed at Tenby, and to that circumstance may be attributed the fact that so much of his geological work dealt with Wales. He was chosen professor of geology at University College, London, in 1848, and lecturer in the same subject at the School of Mines in 1851. Eleven years later he was elected to the presidential chair of the Geological Society, and in 1871 he succeeded Murchison as director-general of the Geological Survey. In 1880 he acted as president of the British Association at Swansea, and in the following year retired from the public service, receiving at the same time the honour of knighthood. He died ten years later at Beaumaris, on 9th December 1891. The scope of his work may be gathered from the titles of the following, which are among his most important papers: "Denudation of South Wales," "Old Glaciers of Switzerland and North Wales," "Glacial Origin of Certain Lakes in Switzerland, the Black Forest, &c.," "The Red Rocks of England," and "River Courses of England and Wales." It will be seen that he was especially interested in tracing out the causes which have determined the physical configuration of a district, and he devoted much attention to the effects produced by ice, his name being identified with the hypothesis, which, however, has never commanded general assent, that in some cases lake-basins have been scooped out by glaciers. Sir Archibald Geikie, who published a biography of him in 1895, has characterized him as combining a faculty for bold and broad generalization with habits of patient observation and cautious induction. He received a Royal medal in 1880 from the Royal Society, of which he became a fellow in 1862, and he was also the recipient of the Neill prize of the Royal Society of Edinburgh in 1866, and of the Wollaston medal of the Royal Geological Society in 1871.

Ramsbottom, manufacturing town and urban district (1894), Lancashire, England, in the Heywood parliamentary division of the county, 13½ miles north of Manchester by rail. A Primitive Methodist chapel was erected in 1889, and a cottage hospital was opened in 1900. It has iron and brass foundries, machine factories, and establishments for calico printing, bleaching, spinning, and manufacturing. Population (1891), 16,726; (1901), 15,920.

Ramsgate, municipal borough and watering-place in the Isle of Thanet parliamentary division of Kent, England, 79 miles east-south-east of London by rail. The inner harbour covers (1899) an area of 12 acres; the outer, of 35 acres. In 1888, 895 vessels entered with 118,636 tons of cargo, and 857 vessels cleared with 114,906 tons. In 1901, 1666, vessels entered with 324,145 tons, and 1531 vessels cleared with 266,458 tons. Steamboats run during the season to London, Tilbury, Margate, Deal, Dover, Calais, and Boulogne. Electric trams connect Ramsgate with Broadstairs and Margate. Extensive improvements were carried out in 1895–96 on the sea-front. They include a new sea-wall and a widened approach to the sands. The corporation opened a public library in 1895. Technical schools occupy part of the same building. Ellington Park, area 12 acres, was opened in 1893. Population of the municipal borough (1891), 24,733; (1901), 27,693.

Ranavalo III. (1864– ——), formerly queen of Madagascar, born in 1864, was a great-niece of Radama I. Her name originally was Rasuaherina, but on succeeding to the throne of Madagascar after the death of Queen Ranavalo II., on 14th July 1883, she assumed the style of Ranavalo III. Although nominally queen, she took no share in the government, which her prime minister, Rainilaiarivony, had controlled since 1864. After placing her on the throne, he married her before the close of the year. Ranavalo became queen just after the French had revived their claim to a protectorate over the island. The Hova Government refusing to admit the claim, war broke out, and several sharp engagements took place. The French bombarded the coast towns, but were unable to reach the interior of the island, where the strength of the Hovas lay. In December 1885 a treaty was concluded by which it was agreed that the government of the French Republic should represent Madagascar in all foreign relations, but that in internal matters the Hova Government should be independent, as formerly. During the next ten years French influence was quietly extended over the island, in spite of the efforts of Rainilaiarivony, who pursued an anti-French policy, encouraging English and American planters and traders. In 1894 differences on commercial and territorial questions arose between the Hova Government and the French, which terminated in war. In 1895 a well-organized

expedition was despatched from France to subjugate the island. Many of the inhabitants sympathized with the invaders, and even the Hovas themselves were divided. Although Ranavalo endeavoured to arouse a martial spirit in her subjects, the French advanced on the capital without encountering any effective opposition. On 30th September they captured Antananarivo. Rainilaiarivony was sent into exile, where he died in the following year; but Ranavalo was suffered to remain as nominal head of the Government, under a strict French protectorate. In 1896, to avoid commercial difficulties with foreign Powers, the island was declared a French colony; but no change was made in the internal administration. Later in the year, however, the civil governor was replaced by a military resident, General Gallieni. A formidable insurrection broke out, which Gallieni suppressed, executing or exiling several prominent members of the Hova administration. Finding that the court had been a centre of intrigue, he abolished the sovereignty by proclamation early in 1897, and exiled Ranavalo to Réunion. In 1899 she was removed to Algiers, but was subsequently permitted to visit Paris.

Ranchi, a town of British India, headquarters of Lohardaga district and of the Chota Nagpur division in Bengal, situated in 23° 22′ N. and 85° 22′ E., 2100 feet above the sea. Population (1891), 20,306. It is an important centre of local trade, and the headquarters of the German Lutheran mission. There is a high school and an industrial school; also three printing-presses, issuing two periodicals, a public library and bar library.

Rand. See GOLD.

Randazzo, a town of the province of Catania, Sicily, Italy, at the north foot of Mount Etna, 25 miles north-west of Giarre by the circum-Etna railway. It is a mediæval-looking town, with Norman walls built of lava, a church dating from the 13th–14th centuries, a former ducal palace (now a prison), several mediæval private houses, and an antiquarian museum. Randazzo is the nearest town to the summit of Mount Etna, 9 miles distant, and stands 2474 feet above sea-level. Population (1881), 9908; (1899), about 8500.

Randers, a town of Denmark, 8 miles inland from Randers Fjord, and 36 miles by rail north by west of Aarhus in Jutland. The high school is housed in a mediæval monastery, which was restored in 1894–97. There is a statue to Steen S. Blicher (1782–1848), the national author of Jutland. There are distilleries and manufactories of gloves, railway carriages, &c., and large slaughter yards. In 1899 the port was entered by 648 vessels of 74,968 tons, and cleared by 652 of 76,275 tons. The chief exports are butter and eggs; the chief imports, sugar, petroleum, coal, and iron. Population (1890), 16,617; (1901), 20,057.

Ranenburg, a district town of Russia, in the government, and 105 miles south of the town, of Ryazan. A considerable trade in grain is carried on, and the inhabitants have gained a reputation for gardening. The population in 1897 was 15,347.

Range-Finder (or TELEMETER).—The judgment of the most highly trained observer, guided by the unassisted eye, is not sufficiently trustworthy to develop to the full the powers of modern weapons. Hence numberless inventors have produced instruments in endless variety to assist the gunner and infantry soldier in determining the distance or "range" to their objective. Such instruments are called telemeters, or, more generally, range-finders.

Among the many inventors of range-finders the following names may be mentioned:—Roosaudre (Austria); Deport, Goulier (France); Amici, Braccialini (Italy); Souchier (Russia); Unge (Sweden); Crehore and Squier, Fiske, Gordon, Leslie, Lewis, Pratt (United States of America); Adie, Barr and Stroud, Christie, Mallock, Watkin, Weldon, &c. (Great Britain).

Nearly all range-finders may be described as instruments which automatically solve a triangle. Usually it is a right-angled triangle, the length of the base of which is known, and one of the sides is the range it is desired to find. They are, in fact, goniometers, but the angle which they measure, whether it may be at the end of the measured base, or that subtended by it, is usually expressed as a function of the angle in terms of the measured base. In fact, the range is recorded directly in metres or yards without calculation. It has frequently been observed that, if a convenient telescope could be devised of sufficient focal length for the travel of the eyepiece in focussing to be made the measure of the distance of the objective from the observer, a perfect range-finder would be obtained.

It is proposed in this article to describe briefly the range-finding instruments in the British services (1) as used in the fleet; (2) by the army in the field; and (3) in harbour defence.

(1) The necessity for a range-finder afloat caused the British Admiralty in 1891 to issue an advertisement in the press inviting inventors to produce an instrument, which would, amongst other conditions, record ranges with an accuracy of 3 per cent. at 3000 yards. The resulting competition was declared in favour of a range-finder the joint invention of Professor Barr of the Glasgow University and Professor Stroud of the Yorkshire College.

The naval range-finder consists of a tube 60 inches in length by 3½ inches in diameter, which contains two telescopes. It is carried on a frame by bearings, in which the tube is free to revolve about its longer axis. To the frame is attached a weight capable of movement within a tank. This weight balances the range-finder and frame upon knife-edges. By means of the handle on the left of the instrument and an altitude worm beneath it, the motion of the tube is governed, and the line of sight is directed on the objective. By partially filling the tank with water, the swinging of the weight in a seaway can be checked. The frame is supported on a pedestal and can rotate in azimuth upon it (Fig. 1). A rubber guard is fitted round the eyepieces. Its functions are to guide the eyes of the observer into the correct position, and to protect them from side light and the distressing effect of wind. It also guards the forehead against the jar occasioned by firing heavy guns. The upper portion of the field presented to the left eye is used as a finder, the lower portion is occupied by the scale upon which the ranges are engraved. The finder is a low-power telescope of large field, to the centre of which the objective is brought. When the telescope is thus correctly aligned the objective will be seen with the right eye largely magnified, but as two partial images separated by a thin black horizontal line. When coincidence of the images is effected by means of the working head, the range can be read off against a pointer from the scale seen with the left eye. For night use, means are provided for illuminating the scale. The range to lights may be ascertained by the use of the astigmatizer, an optical device by which a point of light is drawn out into a vertical streak. A beam of light from the objective falls on each reflector (Fig. 2), and passing through the object glasses, each is received by an arrangement of prisms about the centre of the tube, and reflected through the right eyepiece. Two partial images are thus seen. The images could be united by the rotation of one of the reflectors, but owing to the small base used the necessary movement would be so extremely small that it would be practically impossible to measure it. The difficulty has been surmounted by utilizing fixed reflectors and effecting coincidence by means of a prism of small angle. The deflecting prism is situated in the line of the beam of light from the reflector at the right-hand end of the tube. Its multiplying action is of great delicacy. The angle available for subdivision, to measure ranges between infinity and 250 yards, is only one-third of a degree. In a travel of 6 inches the prism renders accurate measurements possible within the required limits. To bring images of distant objectives into coincidence, the prism must be moved towards the eyepiece, and for near objectives in the opposite direction. The range scale is attached to the prism. A consequent advantage is that the accuracy of the instrument is not affected by back lash arising from wear, or irregularity in the actuating mechanism. When once installed the instrument is always ready for use.

Should adjustment be required it is readily and easily applied. It is not within the sphere of this article to enter into the detail of the adjusting mechanism. For further particulars the reader is referred to the *Proceedings of the Institution of Mechanical Engineers*, 30th January 1896. The working of the range-finder is so simple that its use is quickly learnt by any man who can read, and with little instruction and practice he can "take a range" in 8 to 12 seconds. Besides its principal purpose, in connexion with gunnery, there are minor uses in navigation and nautical surveying to which the range-finder can be applied.

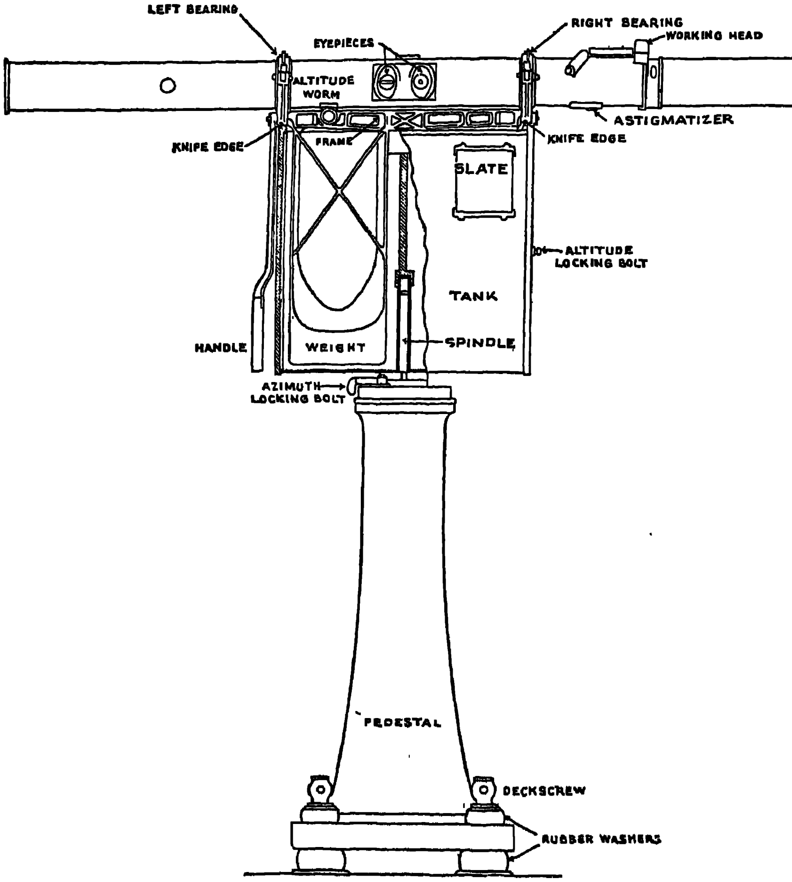

Fig. 1.

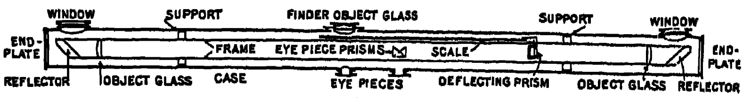

Fig. 2.

With the high speeds of modern war vessels, guns and their objective approach each other so quickly that unless ranges can be communicated from the instrument to the guns with rapidity and accuracy the range-finder is deprived of much of its value. In connexion with the naval range-finder an apparatus is provided, which though not part of the range-finder is sufficiently important to claim passing notice. The apparatus consists of a transmitting and a receiving instrument of clockwork mechanism electrically controlled. In appearance they resemble the ordinary engine-room telegraph, on the dials of which ranges take the place of orders. The transmitter can communicate with a number of receiving instruments, disposed as required in different parts of the ship.

(2) For the army in the field there is but one type of range-finder. To the set of instruments used the name of *mekometer* has been given. The instruments used by the cavalry and infantry are smaller and lighter than those of the artillery pattern, but the principle involved is identical.

The mekometer is practically a box sextant (Fig. 2). Two instruments are used simultaneously at the ends of a base of fixed length. One sextant called the right-angle instrument is fitted with index and horizon glasses permanently inclined at 45°. It consequently measures a right angle. In the other sextant, called the reading instrument, a graduated drum takes the place of the usual index arm and scale. The drum is graduated spirally with a scale of ranges. Both reading and right angle instruments are fitted with a vane of gun metal with a white strip down the centre to facilitate observations. Telescopes of low power can be fitted to the instruments, and two cords of 50 (or 25½) yards are provided with which to measure the base.

Two observers attach the ends of the cord of fixed length (usually 50 yards) to their instruments and separate until it is taut. The observer with the right angle instrument moves into such a position that coincidence of image will be given between the objective and the vane of the instrument at the other end of the base, *i.e.*, he makes ABC a right angle (Fig. 3).

When the right angle is established the observer at C turns the graduated drum of the reading instrument until the image of the vane of the right angle instrument coincides with the direction of the objective. The range AC is then read on the drum. The ranges on the drum are measures of the angle BAC when the base BC is 50 yards.

The mekometer is open to the objection which is common to all range-finders requiring more than one observer. There is always a danger that observers may cause coincidence on different objectives or on different parts of the same objective, and thus inaccuracy in the recorded range must result. The instruments are expected to give an accuracy of less than 2 per cent. at 2000 yards. For ranges over that distance, *i.e.*, for usual artillery ranges, it is desirable to use a double base (100 yards in length), in which case the range registered on the drum must be doubled. This operation, although slight, is a distinct disadvantage, because no calculation, however trifling, is desirable in action; since it adds to the time of taking a range and is a possible source of error. For field artillery, however, a range-finder is only an auxiliary adjunct. The true range can be found by a process of trial and error in as short a time as the mekometer observers take to report it. To quote from the field artillery drill book, "The first round is fired with the elevation due to the range as estimated, or given by the range taker. If it is short the elevation is increased by 100, 200, or 400 yards, and after every round observed short the same alteration is made until a round is observed over; the 'long bracket' is then said to be found. The difference between the two elevations that have bracketed the target is then halved—until the target is enclosed between two rounds the difference of whose elevation is 50 yards, which is termed the "short bracket."[1] Thus the correct elevation is found. It must,

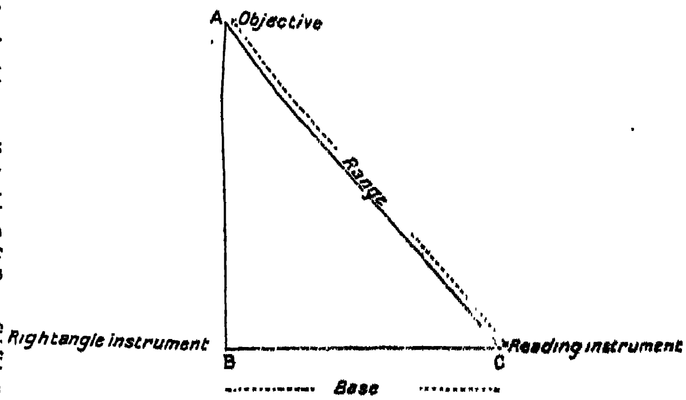

Fig. 3.

however, be remembered that as shrapnel shell is the principal projectile of field artillery, after the correct elevation has been given the true length of time fuze has to be found. This the

[1] At the battle of Omdurman the infantry and machine guns obtained the ranges from the field artillery.

range-finder cannot do. Hence it is that the range-finder for field artillery, although a valuable auxiliary, is not of the same importance as in purely defensive positions such as batteries for harbour defence and land forts. It is believed that in the German and French field artillery a range-finder is not used.

3. For harbour defence, owing to the long range of naval guns, and the fast targets which war vessels present, an accurate range-finder is of first importance. This is largely the case because "ranging" cannot be resorted to in the same manner as in the field, where the targets are comparatively motionless and the effective ranges are less. Successful artillery practice therefore depends, in a great measure, upon the range-finder.

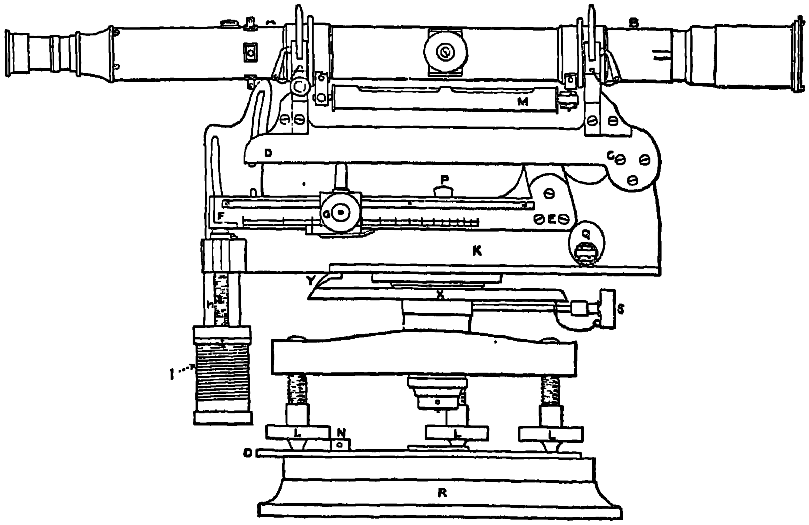

Fig. 4.

The instrument much used in harbour forts is known as the *depression* range-finder. As its name suggests, it solves a triangle in the vertical plane, of which the base is the height of the instrument above sea-level. Its appearance resembles some forms of theodolite (Fig. 4). A framework, capable of rotating in azimuth on a vertical pivot, is supported on a plate carried by levelling screws, L, L, L. To the framework are pivoted two arms DC and FE, at C and E respectively. The arm EF is supported at F by a vertical screw H ending in a drum, upon which, in a spiral scale, the ranges are graduated. Motion in altitude is thus given to the telescope. The arm CD is supported by a slider G. This slider is set by a rack and pinion to the height above sea-level (represented on a scale of feet on EF) at which the instrument may be used. A telescope AB is suitably fitted in jaws at the top of the frame. There are spirit levels at M and Q for adjusting purposes. The telescope is provided with cross wires which can be illuminated for night use. An azimuth circle X and pointer Y enable the direction of any vessel to be indicated, the range of which it is desired to know. The instrument rests on a base plate R to which it is locked by the top-plate O. The observer directs the cross wires of the telescope upon the water line of the objective, by means of the drum I and the azimuth handle P, the top of which just appears in the diagram. The reader watches the arrow on the drum and calls out the ranges as the figures arrive beneath it. The ranges are communicated to the officers at the guns by various devices, which differ according to local requirements.

The details of the *Position Finder* are carefully guarded as confidential. From the brief published descriptions it may be gathered that directing the telescope upon the objective electrically communicates the bearing and range to the gun detachments. The position finder, and also the depression range finder and mekometer, are inventions of Colonel Watkin, C.B.

The greatest advance in practical range-finding for harbour defence, in recent years, has been made in the apparatus to which the name has been given of *automatic sight*.

The mechanism is the invention of Sir George Clarke, K.C.M.G., F.R.S., &c. The principle of the sight is the outcome of a process of evolution in range-finding. The depression range-finder gives ranges from the objective to the range-finder. The position-finder goes a step further, and automatically communicates range and bearing to the vicinity of the guns. But by means of the automatic sight, the same muscular effort which aligns the laying points (or telescope) on the objective, imparts the requisite elevation and direction to the gun.

Such a system of laying ordnance has long been a requirement, but quick-firing guns and smokeless powder demand it as a necessity. The automatic sight renders it possible to regard the individual gun as an independent unit, and with it the largest gun becomes as a rifle in the hands of the man who lays it. Range-finders bind the guns they serve to one objective, and necessitate a rigid fire discipline in order that the guns may be ready to fire at the moment the anticipated range is reported. The automatic sight allows convergence or dispersion of accurate fire, and in a measure restores the elasticity of control of the days of smooth bores. It economizes men, and the gun-layer who uses it does not require the high training necessary for range-finding specialists.

The principle of the apparatus is made clear by Fig. 5. AB is a bar carrying the fore and hind sights, or a telescope fitted at the focus with a pointer. AB is pivoted at C. CD is the attachment of the apparatus to the cradle E. (As the gun recoils through E, the gunner can continue to look over the sights whilst firing.) At right angles to AB is a bar FG, fitted at H with a guide working in a cam plate K. L is a case containing a spring, whose function it is to keep the guide H in contact with the cam. It will be seen that as the gun is elevated or depressed, motion in altitude is imparted to the sight bar AB. The amount of motion is regulated by the form of the cam K, which is cut in accordance with the range table of the gun and the height above sea-level. The sight, therefore, is a depression range-finder, having for its base the height of the axis of the gun above the sea. A compensation for rise and fall of tide is consequently necessary, and is effected by the handle M. M works through a suitably engraved scale and, actuating an eccentric at N, imparts the necessary correcting motion about the pivot R to the cam plate K. The reader is referred for further details to *Garrison Artillery Drill*, 1899, or the *Journal of the United States Artillery*, vol. xiii. p. 323.

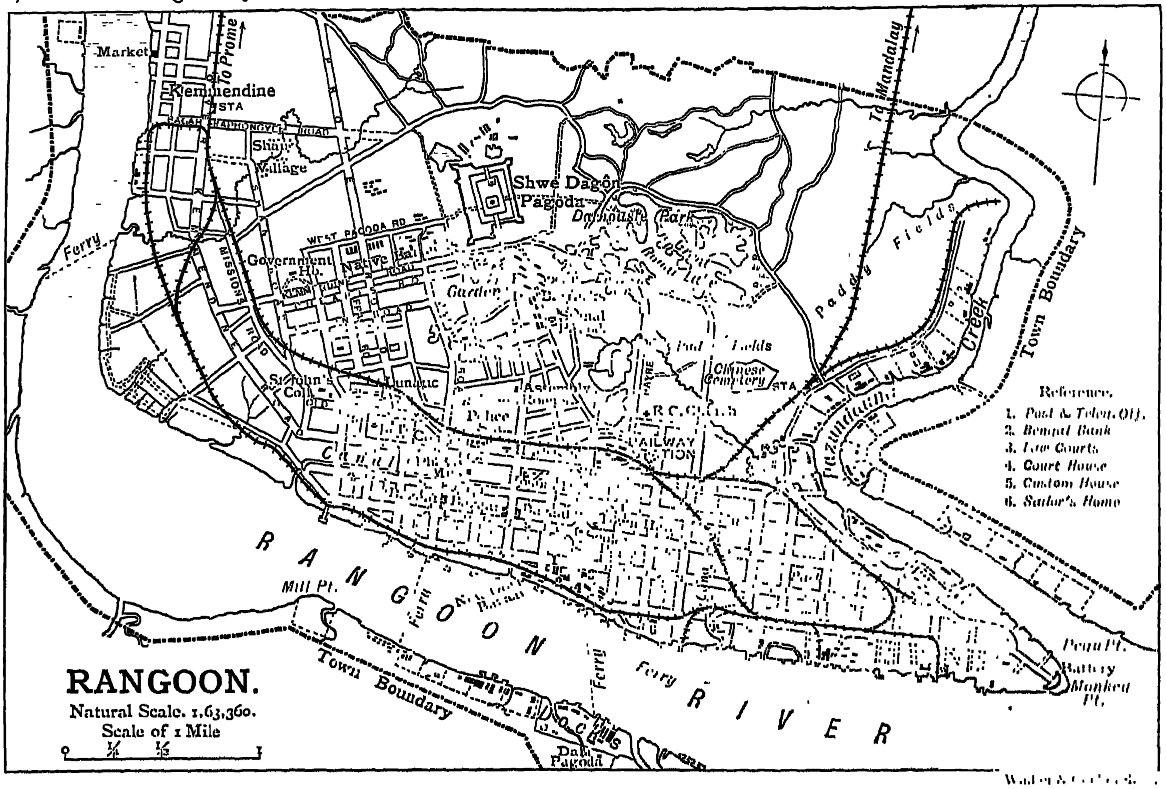
Rangoon, the capital of Burma, situated on the left bank of the river Hlaing or Rangoon, 21 miles from the sea, in 16° 47′ N. and 96° 13′ E. In 1880 Rangoon town was detached from the main district, called Hanthawaddy, and formed into a separate district, with an area of 22 square miles. Population of Rangoon (1891), 181,871; (1901), 232,326.

Until 1874 the management of the town was in the hands of the local government, which devoted itself to raising the centre of the

town above the river level, providing land fit for building purposes from the original swamp, which was flooded at spring-tides, and making roads, bridges, culverts, and surface drains. In 1892 was introduced the Shone sewage system, which now includes 6 miles of sewage mains, 22 miles of gravitating sewers, 4⅜ miles of air mains, and 44 Shone's ejectors. The water-works for Rangoon proper and for the shipping were not completed till 1893. The water-supply is now derived from Victoria Lake, a reservoir near Kokine, five miles distant. The town proper of Rangoon with the Kemmendine suburb is laid out on the block system, each block being 800 by 860 feet, intersected with regular streets. In the extensions of Rangoon to the east and west it has been decided to have no streets less than 50 feet wide. The roads are still lighted by kerosene oil lamps, although Moulmein has adopted a lighting system of oil gas. The lighting extends over 42 miles of roads. Steam tramways run from the town to Pazundaung in one direction and to Alôn and Kemmendine in the other, as well as to the foot of the Shwe Dagôn Pagoda hill. Latterly the erection of masonry buildings, instead of plank houses, has been insisted on in the central portion of the town, with the result that fires have decreased in number. There are two large maidans, or commons, which are used as military parade



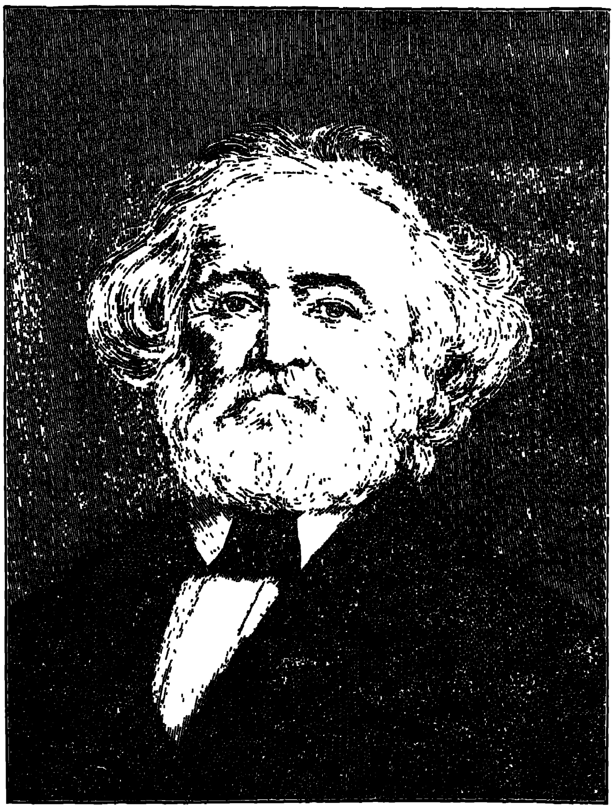
MAP OF RANGOON.

grounds and for racing, as well as for golf links and other purposes of amusement. There is a garden round the Phayre Museum, managed by the Agri-Horticultural Society, and an extremely pretty and well-kept garden in the cantonments under the Pagoda. Beyond these, however, the Royal Lake and Dalhousie Park, with 160 acres of water and 205 acres of well-laid-out and well-timbered park land, form one of the finest recreation grounds of which any city can boast. There are two cathedrals, Church of England and Roman Catholic, a Presbyterian church, and, besides the cantonment church, many other houses of various forms of Christian worship. Religious buildings and lands, indeed, occupy an area in Rangoon out of all proportion to its total size. Christians, Buddhists, Mussulmans, Hindus, Parsis, Armenians, and Jews all own lands and churches, pagodas, temples, mosques, and synagogues. The Buddhist monasteries, in particular, occupy wide spaces in very central portions of the town and cantonments. They are very far from being properly kept, but the ground is devoted in perpetuity to religion, and cannot be resumed, for reasons of public policy. Burial-grounds are equally extensive, and exist in every direction in what were once the outskirts, but are now fast becoming central parts of the city. A large necropolis is being prepared outside Rangoon, and most of the graveyards, many of which are already dangerously overcrowded, will soon be closed. The civil general hospital has accommodation for 368 patients, and over 7000 in-patients and 55,000 out-patients are annually treated in it. The military authorities have a hospital in cantonments. The Dufferin Institute for providing female medical aid to women has a branch and a small hospital in Rangoon, and a new hospital is in course of construction. Contagious diseases, cholera and small-pox, are treated in separate hospitals built outside the crowded part of the town. There are three municipal and eight private markets in Rangoon, which are being improved and extended. Everything, from sacking to jewellery, is sold in them. The introduction of pure water and the establishment of compulsory vaccination have greatly improved the health of Rangoon. The aggregate death-rate, which was 31·41 per mille in 1896, had fallen to 23·16 in 1898–99. The rate is still high, and is due partly to the swampy nature of the outskirts of the town proper, and still more to the deaths among the Hindu immigrants from the Madras Presidency. The death rate among Christians is only 7 per mille. Of the population in 1898–99, the number of Buddhists and Jains was 79,857; Hindus, 57,845; Mahommedans, 28,836; Christians, 12,698, of whom 4686 were natives, 1075 Karens and Shans, and 33 Parsis. The total rainfall in 1898–99 was 109·05 inches. The highest thermometer reading in May was 97·5, and the lowest reading in December 60·8° F. (J. G. Sc.)

Rangpur, or RUNGPORE, a town and district of British India, in the Rajshahi division of Bengal. The town is situated on the little river Ghaghat. Population (1891), 14,216. There is a high school, a normal school, and an industrial school. A public library was established in 1854. The earthquake of 12th June 1897 destroyed many of the public buildings, and diverted the drainage channels.

The DISTRICT of Rangpur has an area of 3486 square miles. The population in 1891 was 2,065,464, showing a slight decrease; average density, 592 persons per square mile. Classified according to religion, in 1891 Mahommedans numbered 1,295,411; Hindus, 768,233; Christians, 243, of whom 86 were Europeans; "others," 1577. In 1901 the population was 2,152,518, showing an increase of 4 per cent. The land revenue and rates in 1897–98 were Rs.11,46,765; number of police, 465; boys at school in 1896–97, 26,068, being 16·3 per cent. of the male population of school-going age; registered death-rate (1897), 38 per thousand. After rice, the most important crop is jute. There are 21 jute presses, with a capital of Rs.5,28,000, producing 181,000 bales, valued at Rs.26,87,000. Tobacco also is largely grown. The Eastern Bengal Railway has two branches, one of which crosses the district to the Brahmaputra, and the other runs north to Cooch Behar. The railway bridge over the Tista at Kaunia was opened in 1901.

Ranke, Leopold von (1795-1886), German historian, was born, 21st December 1795, in the small town of Wiehe, in Thuringia, which then formed part of the electorate of Saxony. His father was an advocate, but his ancestors, so far back as the family can be traced, had been ministers of religion. To the end of his days he maintained the deep religious feeling and family affection which he had acquired as a child. He received his education first at Donndorf, a boarding-school established in an old monastery near his home, and then at Schulpforta. Thence he passed to the University of Leipzig. His studies, both at school and university, were predominantly classical and theological; he received no special training in, and during his early years he displayed no special vocation for, history. The great political events which occurred during his boyhood and youth seem to have had less effect on him than on many of his contemporaries, and he was not carried away either by enthusiastic admiration for Napoleon or by the patriotic fervour of 1813; nor was he implicated in the political movements which during the following years attracted many of the students. He already displayed that detachment of mind which was to be so characteristic of him. At the age of twenty-two he became master in a school at Frankfort-on-the-Oder. He thereby entered the service of the Prussian Government: his birthplace had already been annexed to Prussia. The headmaster was Poppo, the celebrated Grecian. But besides his classical work, Ranke was entrusted with the teaching of history. With the scholar's dislike of text-books, he rapidly acquired a thorough knowledge of the ancient historians, quickly passed on to mediæval times, and here it was that he formed as the ideal of his life the study of universal history—the works of God as displayed in the history of the human race. Here, too, he composed his first work, which deals with the period to which most of his life was to be devoted, *On the History of the Romance and German Races from 1494 to 1516* (Berlin, 1824). To it was appended a critical dissertation on the historians who had dealt with the period, which, showing as it did how untrustworthy was much of traditional history, was to be for modern history as epoch-marking as the critical work of Niebuhr—who in this was his master—had been in ancient history. A copy of the book was sent to the Prussian minister of education, Kampz, the notorious hunter of democrats. Within a week he received the promise of a post at Berlin, and in less than three months was appointed supernumerary professor, with a small salary—a striking instance of the promptitude with which the Prussian Government recognized scientific merit when, as in Ranke's case, it was free from dangerous political opinions. The connexion thus established was to last for fifty years. At the Berlin Library Ranke found a collection of MS. records, chiefly Italian, dealing with the period of the Reformation: from a study of them he found how different were the real events as disclosed in contemporary documents from the history as recorded by most writers; and the result of his researches was embodied in his second work, *The Princes and Peoples of Southern Europe* (1827). (In later editions the title of this was altered to *The Osmans and the Spanish Monarchy in the 16th and 17th Centuries.*) It was now his ambition to continue his exploration of the new world thus opened to him: the Prussian Government provided the means, and in September 1827 he started for Italy. His first sojourn was in Vienna: the friendship of Gentz and the protection of Metternich opened to him the Venetian archives, of which many were preserved in that city—a virgin field, the value of which he first discovered, and which is still unexhausted. He found time, in addition, to write a short book on *Servia and the Servian Revolution*, from material supplied to him by Wuk Stephanowich, a Servian, who had himself been witness of the scenes he related. In 1828 he at last crossed the Alps, and the next three years were spent in Italy. The recommendations of Metternich opened to him almost every library except the Vatican; and it was during these three years of study in Venice, Ferrara, Rome, and other cities, that he obtained that acquaintance with European history which was to make him the first historian of his time. At Rome, as he said, he learned to see events from the inside. He wrote nothing but a critical examination of the story of Don Carlos, but he returned to Germany a master of his craft. He then for a time engaged in an occupation of a different nature, for he was appointed editor of a periodical which Perthes designed to defend the Prussian Government against the democratic press. Ranke, contemptuous in politics, as in history, of the men who warped facts to support some abstract theory, especially disliked the doctrinaire Liberalism so fashionable at the time. He hoped, by presenting facts as they were, to win the adhesion of all parties. We need not be surprised that he failed: men desired not the scientific treatment of politics, but satire and invective. Exposed to the attacks of men like Heyne and Börne, his weakness, if not his venality, was long an article of faith among the Liberals. He did not satisfy the Prussian Conservatives, and after four years the *Historische Politische Blätter* came to an end. Two-thirds of the matter had been contributed by the editor, but the two stout volumes in which the numbers were collected contained the best political thought which had for long appeared in Germany. For Ranke the failure was not to be regretted: the rest of his life was to be wholly devoted to that in which he excelled. During 1834-37 appeared the three volumes of his *History of the Popes*, in form, as in matter, the greatest of his works, containing the results of his studies in Italy. Henceforth



LEOPOLD VON RANKE.
(*By permission of E. Linde and Co.*)

his name was known in all European countries; the English translation by Mrs Austin was the occasion of one of Macaulay's most brilliant essays. Before it was completed he had already begun the researches on which was based the second of his masterpieces, the *History of Germany during the Reformation* (1839–47), a necessary pendant to his book on the Popes, and the most popular of his works in his own country. In 1837 he became full professor; in 1841 Frederick William IV., always ready to recognize intellectual eminence, appointed him Prussian historiographer. Stimulated by this, he brought out his *Nine Books of Prussian History* (1847–48; subsequently expanded to twelve), a work which, chiefly owing to the nature of the subject, makes severe demands on the attention of the reader—he is the "Dryasdust" of Carlyle's Frederick; but in it he laid the foundation for the modern appreciation of the founders of the Prussian State. He took no immediate part in the movements of 1848, but in the following years drew up several memoranda for the king, whom he encouraged in his efforts to defend the character and identity of the Prussian State against the Revolution. Though never admitted into the inner circle of the king's associates (for indeed what place was there for him among the Gerlachs, Stahls, and Radowitzs?), he found the king the most appreciative of readers and stimulating of companions, and the queen one of the most faithful of his friends; in biographical works and on other occasions he always defended the memory of the unfortunate monarch. A friend even more sympathetic he found in Maximilian II. of Bavaria, whom he advised in his expansive schemes for the promotion of learning and letters. In the quieter years that followed he wrote the third of his masterpieces, the *History of France, chiefly in the 16th and 17th Centuries* (1852–61), which was followed by the *History of England, chiefly in the 17th Century* (1859–67). This, the longest of his works, added much to existing knowledge, especially as to the relations between England and the Continent, but it lacked something of the freshness of his earlier books; he was over seventy when it was completed, and he was never quite at home in dealing with the parliamentary foundations of English public life. It is impossible even to enumerate his other and minor works, which chiefly deal with the German history of the last three centuries. In his later years his small alert figure was one of the most distinguished in the society of Berlin, and every honour open to a man of letters was conferred upon him. He was ennobled in 1865, and in 1885 received the title of Excellenz. When the weakness of his eyes made it necessary for him to depend almost entirely on the service of readers and secretaries, in his eighty-first year he began to write the *History of the World*. Drawing on the knowledge accumulated during sixty years, he lived to bring it down to the time of the Crusades.

Ranke married, at Windermere, in 1843, Miss Clara Graves, daughter of an Irish barrister. She died in 1870, leaving two sons and one daughter.

At the time of his death Ranke was, not in his own country alone, generally regarded as the first of modern historians. It is no disparagement to point out that the recognition he obtained was due not only to his published work, but also to his success as a teacher. His public lectures, indeed, were never largely attended, but in his more private classes, where he dealt with the technical work of a historian, he trained generations of scholars: no one since Heyne has had so great an influence on German academical life, and for a whole generation the Berlin school had no rival. He took paternal pride in the achievements of his pupils, and delighted to see, through them, his influence spreading in every university. While his own work lay chiefly in more modern times, he trained in his classes a school of writers on German mediaeval history. As must always happen, it is only a part of his characteristics which they learnt from him, for his greatest qualities were incommunicable. The critical method which has since become almost a formal system, aiming at scientific certainty, was with him an unexampled power, based on the insight acquired from wide knowledge, which enabled him to judge the credibility of an author or the genuineness of an authority; but he has made it impossible for any one to attempt to write modern history except on the "narratives of eye-witnesses and the most genuine immediate documents" preserved in the archives. From the beginning he was determined never to allow himself to be misled, in his search for truth, by those theories and prejudices by which nearly every other historian was influenced—Hegelianism, Liberalism, Romanticism, religious and patriotic prejudice; but his superiority to the ordinary passions of the historian could only be attained by those who shared his elevation of character. "My object is simply to find out how the things actually occurred." "I am first a historian, then a Christian," he himself said. In another way no historian is less objective, for in his greatest works the whole narrative is coloured by the quality of his mind expressed in his style. An enemy to all controversy and all violence, whether in act or thought, he had a serenity of character comparable only to that of Sophocles or Goethe. Apt to minimize difficulties, to search for the common ground of unity in opponents, he turned aside, with a disdain which superficial critics often mistook for indifference, from the base, the violent, and the common. As in a Greek tragedy, we hear in his works the echo of great events and terrible catastrophes: we do not see them. He also made it a principle not to relate that which was already well known, a maxim which necessarily prevented his works attaining a popularity with the unlearned equal to their reputation among historians. But no writer has surpassed him in the clearness and brevity with which he could sum up the characteristics of an epoch in the history of the world, or present and define the great forces by which the world has been influenced. His classicism led to his great limitations as a historian. He did not deal with the history of the people, with economic or social problems—the dignity of history was to him a reality: he belonged to the school of Thucydides and Gibbon, not of Macaulay and Taine; he deals by preference with the rulers and leaders of the world, and he strictly limits his field to the history of the state, or, as we should say, political history; and in this he is followed by Seeley, one of the greatest of his adherents. The leader of modern historians, he was in truth a man of the *ancien régime*.

There is a collected edition of Ranke's works in fifty-four volumes, published by Dunkler and Humblot, 1881, &c. This does not include the *Weltgeschichte*. The last two volumes contain letters and autobiographical fragments. Besides the *History of England* and the *History of the Papacy*, there are English translations of his *History of the Romance and Teutonic Peoples* by Ashworth; of the *Princes and Peoples of Southern Europe*, and of the first volume of the *History of the World*, by Prothero. See also the article in the *Allgemeine deutsche Biographie* by Dove.—Guglia. *Leopold v. Ranke*. 1893. Ottokar Lorenz. *Die Geschichtswissenschaft*. Berlin, 1891.—Lord Acton on "German Schools of History," in *English Historical Review*, vol. i. No. i.—Guilland. *L'Allemagne Nouvelle et ses historiens*. Paris, 1899.

(J. W. He.)

Raoult, François Marie (1830–1901), French chemist, was born at Fournes, in the Département du Nord, on 10th May 1830. He became *aspirant répétiteur* at the lycée of Rheims in 1853, and after holding several intermediate positions was appointed in 1862 to the professorship of chemistry in Sens lycée, where he prepared the

thesis on electromotive force which gained him his doctor's degree at Paris in the following year. In 1867 he was put in charge of the chemistry classes at Grenoble, and three years later he succeeded to the chair of chemistry, which he held until his death on 1st April 1901. Raoult's earliest researches were physical in character, being largely concerned with the phenomena of the voltaic cell, and later there was a period when more purely chemical questions engaged his attention. But his name is best known in connexion with the work on solutions, to which he devoted the last two decades of his life. His first paper on the depression of the freezing points of liquids by the presence of substances dissolved in them was published in 1878; and continued investigation and experiment with various solvents, such as benzene and acetic acid, in addition to water, led him to the discovery of a simple relation between the molecular weights of the substances and the freezing point of the solvent, which he expressed as the "loi générale de la congélation," that if one molecule of a substance be dissolved in 100 molecules of any given solvent, the temperature of solidification of the latter will be lowered by 0·63° C. Another relation at which he worked was that the diminution in the vapour-pressure of a solvent, caused by dissolving a substance in it, is proportional to the molecular weight of the substance dissolved—at least when the solution is weak. These two generalizations not only afforded a valuable new method of determining the molecular weights of substances in the liquid state, but have also been utilized by van 't Hoff and Ostwald, among other chemists, in support of the hypothesis of electrolytic dissociation in solutions. An account of Raoult's life and work was given by Professor van t' Hoff in a memorial lecture delivered before the London Chemical Society on 26th March 1902.

Rapallo, a town and winter resort of the province of Genoa, Liguria, Italy. It occupies a beautiful and well sheltered situation on the east side of the Gulf of Rapallo, 18 miles east by south from Genoa, on the railway to Pisa. It has a fine church, a mediæval castle (now used as a prison), and a Roman bridge. Olives and other fruit are grown. Lace is made, and coral and tunny fishing carried on. Rapallo is a zoological and meteorological station. Population (1899), 3000.

Rappoltsweiler, in French *Ribeauville*, a town of Germany, in Alsace-Lorraine, district of Upper Alsace, 33 miles by rail south-south-west of Strasburg, is still in part surrounded by walls, and is known as "the pipers' town." In the town-hall is a collection of antiquities. The parish church (Roman Catholic) dates from 1473. Population (1900), 6099.

Rasht (*Resht*), the capital of the province of Gílán, in Persia. A carriage road connecting it with Tehran was opened to traffic in 1899. There is also a good main road from the city to Pír Bazar, the depôt for goods coming from Enzeli, the port on the Caspian, 16 miles north of Rasht. Conflagrations are frequent, particularly in the months of December and January, when hot, dry winds, resembling the foehn of the Alps, come down from the snow-capped Elburz. In December 1899 several caravanserais and bazaars, containing large quantities of merchandise, were burned. For 1897–98 the value of the exports was estimated at £900,000, and that of the imports at £850,000. The principal exports were: rice, £270,000; dry fruit, £190,000; fish, £70,000; sheep and cattle, £40,000; wool, £10,000; cotton, £270,000; and the principal imports: sugar, £400,000; silk-worm seed, £40,000; cotton goods, £240,000; petroleum, £15,000; glass and china, £30,000. The trade in dried (silkworm) cocoons has increased remarkably since 1893, when 76,150 ℔, valued at £6475, were exported, but in 1900 no less than 1,615,488 ℔, valued at £150,265, were exported.

Raspopina, a Cossack village of Russia, in the province of the Don Cossacks, on the right bank of the Don river, 85 miles north-west of Tsaritsyn. It has considerable trade in corn and cattle, and in 1897 had a population of 15,330.

Rastatt, a town of Germany, grand-duchy of Baden, 15 miles by rail south-west of Carlsruhe. Rastatt ceased to be a fortress in 1890. It has a museum and an industrial school, and manufactures cooking-stoves, tobacco, &c. Population (1885), 11,743; (1900), 13,940.

Rastenburg, a town of Prussia, province of East Prussia, 64 miles by rail south-east of Königsberg. It has a parish church dating from 1359, a large lunatic asylum, a provincial stud, and iron-works, oil and flour mills, breweries, &c. Population (1885), 7189; (1900), 11,140.

Rathenow, a town of Prussia, on the Havel, 45 miles west by north of Berlin by rail. Rathenow has a Protestant and a Catholic (1893) church, a *real* progymnasium, a higher-grade school, 9 optical instrument, 4 stove, 2 machinery, and 2 furniture works, 2 shipbuilding yards, an asbestos and 2 glue factories. Population (1880), 11,394; (1900), 21,043.

Ratibor, a town of Prussia, Silesia, 97 miles by rail south-east of Breslau and 13 from the Austrian frontier, on the Oder, with manufactures of ironware, furniture, tobacco, paper, sugar, glass, machinery, chemicals, &c.; it also produces vegetables. Population (1885), 19,524; (1900), 25,236.

Ratisbon, in German *Regensburg*, a town and episcopal see of Bavaria, Germany, district Upper Palatinate, on the Danube, 86 miles by rail north-north-east from Munich. The church of St Ulrich contains a large portion of the antiquarian collections of the Historical Society, the rest being in the St Erhard House. The northern gate of the old Roman town was unearthed in 1885. Among the public institutions should be mentioned the public library, picture gallery, botanical garden, institute for glass staining, and some seminaries. Population (1885), 36,093; (1900), 45,426.

Ratlam, or Rutlam, a native state of India, in the Malwa agency. Area, 729 square miles. Population (1881), 87,314; (1891), 89,160. Estimated gross revenue, Rs.1,30,000; tribute, Rs.84,000. The chief, whose title is raja, is a Rahtor Rajput of the Jodhpur family. The town of Ratlam is 1577 feet above the sea. Population (1881), 31,066; (1891), 29,822. It is a junction on the Rajputana–Malwa Railway, and an important centre of trade, especially in opium. In 1897–98 the number of chests of opium exported through the Ratlam sub-agency was 1428, paying a duty of Rs.8,02,450.

Ratnagiri, a town and district of British India, in the Konkan division of Bombay. The town is on the seacoast, 136 miles south of Bombay. Population (1881), 12,616; (1891), 14,303. Ratnagiri is a seaport, with a lighthouse, and an old fort sheltering a tidal creek. It has a good water supply. There is a Government high school and a school of industry. The district of Ratnagiri has an area of 3922 square miles. Population (1881), 997,090; (1891), 1,105,926. In 1901 the population was 1,166,890, showing an increase of 6 per cent., compared with an increase of 11 per cent. in the previous decade. Land revenue and rates, Rs.9,84,448, the incidence of assessment being just over 8 annas per acre; number of police, 703; children at school (1897–98), 18,781, being 2·1 per cent. of the total population;

registered death-rate (1897), 30 per thousand. The Bombay survey tenure has not been extended to the district, which possesses a peculiar land system, called *khoti*. Fishing and maritime trade are active, there being twenty-nine ports altogether.

Ratnapura (which means "The City of Gems") is the chief town in the province of Sabaragamuwa, Ceylon, and is the centre of a native industry in digging for precious stones—rubies, sapphires, cat's-eyes, &c.—which has existed from time immemorial. There is also much rice and fruit cultivation and planting of tea in the district. Population of town, about 4100; of district, 133,000; of province, 322,000.

Rat Portage, a town and port of entry in Ontario, Canada, and the chief town of Rainy River district, situated in 49° 47′ N., 94° 30′ W., at an altitude of 1087 feet above the sea. It is 133 miles by rail east of Winnipeg, on the Canadian Pacific Railway, and at the outlet of the Lake of the Woods. The Winnipeg river has at this point a fall of 16 feet, which, with the lake as a great reservoir, furnishes an abundant and unfailing water-power. The industrial establishments comprise reduction works, saw-mills, and flour-mills, one of the latter being the largest in Canada. It is the distributing point for the gold mines of the district, and during the summer months steamboat communication is maintained on the lake. There is important sturgeon fishing. Population (1891), 1806; (1901), 5202.

Raudnitz (Czech, *Roudnice nad Labem*), a district town on the Elbe, in northern Bohemia. Its chief attraction lies in the interesting and valuable collections in the 17th-century château of Prince Lobkowitz. These include an extensive library, with a large number of the earliest specimens of printing and valuable MSS., together with a series of pictures from the time of Charles V. to the Thirty Years' War. In 1350 Rienzi, "the last of the tribunes," was confined by the emperor Charles IV. in the castle, which then occupied the site of the present château, previous to his despatch under arrest to the Pope at Avignon. The chief industries comprise tanning, distilling, brewing, and the manufacture of liqueurs, oil, vinegar, malt, chemicals, and metal goods; its trade also including live stock, timber, and agricultural produce. In 1890 the population of the commune was 6615, and of the town 3349; in 1900, 7973, chiefly Czech.

Ravenna, a city and archiepiscopal see of Italy, Emilia, capital of the province of Ravenna, stands in a marshy plain, more than 4 miles from the sea, and 45 miles by rail east of Bologna. In addition to its numerous ancient churches, for which it is principally famous, it possesses an archiepiscopal palace (5th century); the remains of the palace of Theodoric; the tomb of Theodoric (6th century); the small temple (1482, rebuilt 1782) which contains the tomb of Dante, who died here in 1321; Byron's house; the Academy of Fine Arts (1827), with schools of design, a picture gallery, and a library; a public library, with several incunabula and MSS.; a small museum; a statue of Pope Clement XII. (1738); a monument to the statesman Farini; outside the walls, a monument to Gaston de Foix and to the victory which the French won over the Hispano-Papal troops in 1512. The industries are few—the growing of wine, breeding of silkworms, making of agricultural instruments, printing, and the manufacture of laces being the chief. There is a technical school. In 1897 the port (4 miles distant) was cleared by 1088 vessels of 52,729 tons. Population (1881), 34,270; (1901), 63,839.

Rawalpindi, a city of British India, which gives its name to a district and a division in the Punjab. The city is situated on both banks of the river Leh, 1726 feet above the sea, 111 miles east by south of Peshawar; it has a railway station. Population (1881), 52,975; (1891), 73,795; municipal income (1897–98), Rs.2,09,817; death-rate (1897), 44 per thousand. It is the headquarters of a military district, with a strong force of all arms and there is a first-class fortress, containing an arsenal. Rawalpindi is the starting-point of the cart-road to Murree, and the centre of trade with Kashmir. There is an annual horse fair. A Gordon mission college was opened in 1893. There are three high schools, a normal school, an industrial school, and schools for European boys and girls. There are eight printing-presses, issuing three newspapers.

The district of RAWALPINDI has an area of 4844 square miles. Population (1881), 820,512; (1891), 887,194. In 1901 the population was 780,080, showing a decrease of 12 per cent., compared with an increase of 8 per cent. in the preceding decade. Land rev nue and rates (1897–98), Rs.11,38,686, the incidence of assessment being 11 annas per acre; cultivated area, 739,172 acres, of which 58,111 were irrigated from wells, &c.; number of police, 1056; number of schools, 623, attended by 15,483 boys, being 16·7 per cent. of the boys of school-going age; death-rate (1897), 32·7 per thousand. The principal crops are wheat, millet, pulse, barley, maize, oil-seeds, and cotton. The district is traversed by the main line of the North-Western Railway, crossing the Indus at Attock, and also by a branch to the Indus at Kushalgarh for Kohat; total length, 167 miles. Another branch roughly following the Indus, from Attock to Mari, was opened in 1899. The two boundary rivers are navigable for 178 miles.

The division of RAWALPINDI lies in the north of the Punjab, between Lahore and Peshawar. It consists of the six districts of Sialkot, Gujrat, Gujranwala, Shahpur, Jhelum, and Rawalpindi. Total area, 20,738 square miles. Population (1891), 3,560,699; average density, 172 persons per square mile.

Rawlinson, George (1812–1902), English scholar and historian, was born at Chadlington, Oxfordshire, 23rd November 1812, being the younger brother of Sir Henry Rawlinson (*q.v.*). Having taken his degree at Oxford (from Trinity College) in 1838, he was elected to a fellowship at Exeter College in 1840, of which from 1842 to 1846 he was fellow and tutor. He was ordained in 1841; was Bampton lecturer in 1859, and Camden professor of ancient history from 1861 to 1889. In 1872 he was appointed canon of Canterbury, and after 1888 he was rector of All Hallows, Lombard Street. In 1873 he was appointed to the office of proctor in Convocation for the Chapter of Canterbury. He married Louisa, daughter of Sir R. A. Chermside, in 1846. His chief publications are his translation of the *History of Herodotus* (in collaboration with his brother Sir Henry Rawlinson, and Sir Gardner Wilkinson), 1858–60; *The Five Great Monarchies of the Ancient Eastern World*, 1862–67; *The Sixth Great Oriental Monarchy* (Parthian), 1873; *The Seventh Great Oriental Monarchy* (Sassanian), 1875; *Manual of Ancient History*, 1869; *Historical Illustrations of the Old Testament*, 1871; *The Origin of Nations*, 1877; *History of Ancient Egypt*, 1881; *Egypt and Babylon*, 1885; *History of Phœnicia*, 1889; *Parthia*, 1893; *Memoir of Major-General Sir H. C. Rawlinson*, 1898. He was a contributor to the *Speaker's Commentary*, the *Pulpit Commentary*, Smith's *Dictionary of the Bible*, and various similar publications; and he was the author of the article "Herodotus" in the ninth edition of the *Encyclopædia Britannica*. He died 7th October 1902.

Rawlinson, Sir Henry Creswicke (1810–1895), English soldier and Orientalist, was born at Chad-

lington, Oxfordshire, on 11th April 1810. In 1827 he went to India as cadet under the East India Company; and after six years' life with his regiment as subaltern, during which time he had become proficient in the Persian language, he was sent to Persia in company with some other English officers who were entrusted with the task of drilling and reorganizing the Shah's troops. It was during the years he spent in Persia at this time that he was first attracted to the study of inscriptions, more particularly those in the hitherto undeciphered cuneiform character. In the course of the two years during which he was in its immediate neighbourhood, he transcribed as much as he was able of the great cuneiform inscription in the Persian language on the rock at Behistun; but his exertions in this direction were temporarily checked by the friction between the Persian Court and the English Government, which ended in the departure of the English military officers from the Shah's dominions.

His experience and the ability he had shown in Persia gained him the appointment as political agent at Kandahar in 1840. In that capacity he served for three years with conspicuous success, his political labours being as meritorious as was his gallantry during various engagements in the course of the Afghan war; for these he was rewarded by the distinction of C.B. in 1844. A fortunate chance, by which he became personally known to the governor-general, led to his being appointed, at his own desire, as political agent in Turkish Arabia; thus he was enabled to settle in Baghdad, where his official duties were sufficiently light to allow of his devoting much time to the cuneiform studies which so strongly attracted him. He was now able, under considerable difficulties and with no small personal risk, to make a complete transcript of the Behistun inscription, which he was also successful in deciphering and interpreting. Having collected a large amount of invaluable information on this and kindred topics, in addition to much geographical knowledge gained in the prosecution of various explorations (including visits with Mr Layard to the ruins of Nineveh), he returned to England on leave of absence in 1849. He remained at home for two years, in the course of which he received from various learned societies the honour due to his achievements in connexion with the decipherment of Babylonian and Assyrian inscriptions; published, in 1851, his Memoir on the Behistun inscription; and was promoted to the rank of lieutenant-colonel. He disposed of his valuable collection of Babylonian, Sabæan, and Sassanian antiquities to the Trustees of the British Museum, who also made him a considerable grant to enable him to carry on the Assyrian and Babylonian excavations initiated by Layard. In 1851 he returned to his post at Baghdad. The excavations were carried on under his direction with valuable results, among the most important being the discovery of material that greatly contributed to the final decipherment and interpretation of the cuneiform character. An accident with which he met in 1855 hastened his determination to return to England and devote himself to the elaboration of the knowledge he had gained by his researches, and consequently in that year he resigned his post in the East India Company. On his return to England the distinction of K.C.B. was conferred upon him, and he was appointed a crown director of the East India Company. The remaining forty years of his life were full of activity—political, diplomatic, and scientific—and were mainly spent in London. In 1858 he was appointed a member of the first India Council, but resigned in 1859 on being sent to Persia as envoy extraordinary and minister plenipotentiary. The latter post he held only for a year, owing to his dissatisfaction with circumstances connected with his official position there. Previously he had sat in Parliament as M.P. for Reigate from February to September 1858; he sat again as M.P. for Frome 1865–68. He was appointed to the Council of India again in 1868, and continued to serve upon it until his death. He was a strong advocate of the forward policy in Afghanistan, and counselled the retention of Kandahar. His views were more particularly expressed in *England and Russia in the East*, 1875. He was a Trustee of the British Museum from 1876 till his death. He was created G.C.B. in 1889, and a baronet in 1891; was president of the Geographical Society from 1874 to 1875, and of the Asiatic Society from 1878 to 1881; and received honorary degrees at Oxford, Cambridge, and Edinburgh. He married, in September 1862, Louisa Caroline Harcourt Seymour, who bore him two sons and died in 1889. He died in London on 5th March 1895. His published works, which were very largely concerned with his remarkable achievement in the transliteration and decipherment of the cuneiform character, and his equally remarkable geographical knowledge, include (exclusive of minor contributions to the publications of learned societies) four volumes of cuneiform inscriptions, published under his direction between 1870 and 1884 by the Trustees of the British Museum; *The Persian Cuneiform Inscription at Behistun*, 1846–51, and *Outline of the History of Assyria*, 1852, both reprinted from the Asiatic Society's Journals; *A Commentary on the Cuneiform Inscriptions of Babylon and Assyria*, 1850; *Notes on the Early History of Babylonia*, 1854; *England and Russia in the East*, 1875. He contributed to the *Encyclopædia Britannica* (ninth edition) the articles on Baghdad, the Euphrates, and Kurdistan, and several other articles dealing with the East; and assisted in editing a translation of Herodotus by his brother, Canon George Rawlinson. (R. F. S.)

Rawlinson, Sir Robert (1810–1898), English engineer and sanitarian, was born at Bristol on 28th February 1810. His father was a mason and builder at Chorley, Lancashire, and he himself began his engineering education by working in a stonemason's yard. In 1831 he obtained employment under Jesse Hartley in the engineer's office at the Liverpool docks, and for four years from 1836 he was engaged under Robert Stephenson as assistant resident engineer for the Blisworth section of what is now the London and North-Western main line from London to the North. Returning to Liverpool, he spent some years as assistant surveyor to the corporation—a position in which he doubtless had ample opportunities of studying the connexion between dirt and disease—and then in 1844 accepted an engineering post on the Bridgewater Canal. Three years later he returned to Liverpool, to superintend the design and construction of the famous brick arched ceiling in the St George's Hall, in succession to his friend H. L. Elmes, who was obliged to give up the work in consequence of illness that quickly proved fatal. During this period Rawlinson's reputation as a sanitarian had been growing, and when the Public Health Act was passed in 1848 he was appointed one of the first inspectors under it. In the course of his duty he had to inspect many of the chief towns of England, and the reports he was obliged to make of the insanitary conditions he found brought him in many cases into great unpopularity with the municipal rulers whose shortcomings he exposed. Seven years later a still wider field was opened to his energies. Early in 1855 popular feeling was so aroused by the waste of life that was going on among the British troops in the Crimea through disease, and by the mismanagement of the campaign, that the Aberdeen Ministry was forced to resign, and Lord Palmerston, who then became prime minister,

had to adopt vigorous measures for improving the condition of affairs. To this end a Sanitary Commission, consisting of Rawlinson and two medical members (Dr Sutherland and Dr H. Gavin), was despatched, with full and absolute powers from the War Office, to do whatever it thought would lead to better hygienic conditions in camp and hospital. The Commission reached Constantinople in March, and, by insisting on what now seem the most simple and obvious precautions, succeeded within a few weeks in reducing the death-rate in the Levantine hospitals from 42 to $2\frac{1}{4}$ per cent. Passing on to the Crimea, it effected a similar improvement there, and by the end of the year the health of the whole British army in the field was even better than it enjoyed at home. The lesson was not thrown away, and from that time forward sanitary measures were systematically adopted, not only by the British but also by other armies of the world, which resulted in a large diminution of the death-rate from disease. Rawlinson's next great public service, for which he was made C.B. in 1865, was in connexion with the distress caused in Lancashire by the collapse of the cotton-manufacturing industry consequent on the American Civil War. In 1863 it was suggested that, in order to provide employment for the starving operatives, the Government should start works of "utility, profit, and ornament," and Rawlinson being sent to make an official investigation into the question, reported, after visiting nearly 100 towns, that $1\frac{1}{2}$ million sterling might be advantageously expended in providing water-supply and drainage, forming streets, &c., in those places. The result was that the Treasury was authorized to advance £1,200,000 (the amount was afterwards increased) at $3\frac{1}{2}$ per cent. for carrying out such works, which proved of enormous public benefit. In 1866 he acted as chairman of the Royal Commission on the Pollution of Rivers, and a few years later was appointed chief engineering inspector to the Local Government Board; on retiring from this position in 1888 was promoted to be K.C.B. In 1894 he served as president of the Institution of Civil Engineers. He died in London on 31st May 1898. (H. M. R.)

Rawtenstall, a municipal borough (since 1891) of Lancashire, England, in the Rossendale parliamentary division, 12 miles south-east of Blackburn. Liberal Club buildings were erected in 1894, and the Grand Theatre in 1899. Population (1881), 28,913; (1901), 31,052.

Rayleigh, John William Strutt, 3RD BARON (1842——), English physicist, was born in Essex on 12th November 1842, being the son of the second baron. Going to Trinity College, Cambridge, he graduated as senior wrangler in 1865, and obtained the first Smith's prize of the year, the second being gained by Professor Alfred Marshall. He married in 1871 a sister of the Right Hon. A. J. Balfour, and succeeded to the title in 1873. From 1879 to 1884 he was Cavendish professor of experimental physics in the University of Cambridge, in succession to Clerk Maxwell; and in 1887 he accepted the post of professor of natural philosophy at the Royal Institution of Great Britain. His early mathematical and physical papers, written under the name of J. W. Strutt, made him known over Europe; and his powers rapidly matured until, at the death of Clerk Maxwell, he stood at the head of British physicists, Sir George Stokes and Lord Kelvin alone excepted. The special feature of his work is its extreme accuracy and definiteness; he combines the highest mathematical acumen with refinement of experimental skill, so that the idea of ranking him as higher in one department than another does not arise. His experimental investigations are carried out with plain and usually home-made apparatus, the accessories being crude and rough, but the essentials thoughtfully designed so as to compass in the simplest and most perfect manner the special end in view. A great part of his theoretical work consists in resurveying things supposed superficially to be already known, and elaborating their theory into precision and completeness. In this way he has gone over a great portion of the field of physics, and in many cases has either said the last word for the time being, or else started new and fruitful developments. Possessing an immense range of knowledge, he has filled up lacunæ in nearly every part of physics, by experiment, by calculation, and by clear accurate thought. The following branches have especially felt his influence:—chemical physics, capillarity and viscosity, theory of gases, flow of liquids, photography, optics, colour vision, wave theory, electric and magnetic problems, electrical measurements, elasticity, sound, and hydrodynamics. The numerous scientific memoirs in which his original work is set forth are being collected in four large volumes, under his own editorship. His most extensive single work is a book on *Sound*, which, in the second edition, has become a treatise on vibrations in general, and is one of the finest examples of a scientific treatise extant. His familiarity with the methods of mathematical analysis and a certain refinement of taste in their application have resulted in great beauty of form. His papers are often difficult to read, but never diffuse or tedious; his mathematical treatment is never needlessly abstruse, for when his analysis is complicated it is only so because the subject-matter is complicated. Of discoveries superficially sensational there are few or none to record, and the weight of his work is for the most part only to be appreciated by professed physicists. One remarkable discovery, however, of general interest, was the outcome of a long series of delicate weighings and minute experimental care in the determination of the relative density of nitrogen gas undertaken in order to determine the atomic weight of nitrogen namely, the discovery of argon, the first of a series of strange new substances, chemically inert, which occur, some only in excessively minute quantities, as constituents of the earth's atmosphere (see the article ARGON in these new volumes, which is from his pen). He was also the author of the articles OPTICS and WAVE THEORY in the ninth edition of this Encyclopaedia. Lord Rayleigh has taken some interest in abnormal psychological investigations, and has long been a member and vice president of the Society for Psychical Research. He was one of the few selected for admission to the Order of Merit instituted in connexion with the coronation of His Majesty King Edward VII.

For a popular but authentic account of some of Lord Rayleigh's scientific work and discoveries, see an article by Sir Oliver Lodge in the *National Review* for September 1898.

Razgrad, chief town of a department in the principality of Bulgaria, on the Biéli-lom or Ak-lom, near a station on the railway from Rustchuk to Varna, 40 miles south-east of Rustchuk. Owing to evacuation by the Turks after the Russo-Turkish war of 1877, a large part of the town lapsed into ruin, but it is regaining its prosperity, and has a large agricultural and general trade. It possesses a magnificent mosque, built in 1614 by Ibrahim Pasha, but it is now in a partly ruined condition. Population (1892), 13,295.

Reading, the county town and a municipal, parliamentary, and county borough and market town of Berkshire, England. It lies on the Kennet, just above its junction with the Thames, 36 miles by rail and 47 by river west of London. Its situation in a fertile vale, and in

proximity to the charming reaches of the upper Thames, has of late years made it a favourite place of residence; and through the excellent railway accommodation provided by the Great Western, South-Western, and South-Eastern railways, it may be said to have been drawn into suburban London. The site of the old Hospice of St John is now occupied by the University Extension College, opened in 1892, which, affiliated to Oxford University and with accommodation for 600 students, was the first attempt to popularize higher university education. Its agricultural department is particularly flourishing. The Lady Warwick Hostel, named after its founder, is an institution for instructing young women in the lighter branches of agriculture—fruit and poultry-farming, and gardening. The Great Western Railway station, so long an eyesore to passengers, has been rebuilt, the lines relaid, and thereby the through express traffic greatly facilitated. The great biscuit manufactory of Huntley and Palmer has lately been much enlarged, and employs nearly 5000 hands. The extensive seed nurseries of Messrs Sutton, which vie with those of Erfurt and Quedlinburg in Germany, cover nearly 10,000 acres, and are of world-wide renown. Adjoining the free library is a museum containing a collection of Romano-British antiquities from Silchester. A public park 59 acres in extent, the gift of Mr G. Palmer, was opened in 1891.

Besides its manufactures, which are in a flourishing condition, and embrace sauces, velvet, sacking, silk, ribbons, and tin boxes, Reading is also an important mart for corn and other agricultural produce. Reading returns only one member to Parliament since 1885, in which year the parliamentary borough was also extended. Area of municipal borough, 5878 acres; area of parliamentary borough, 2441 acres. Population (1891), 60,054; (1901), 72,214.

Reading, a city of Pennsylvania, U.S.A., the capital of Berks county. It is situated in 40° 20′ N. and 75° 55′ W., on the east bank of the Schuylkill river, on the Schuylkill canal, and on the Pennsylvania, the Philadelphia and Reading, and the Wilmington and Northern railways, in the south-eastern part of the state, at an altitude of 206 feet. Laid out on a fairly level site, the city is divided into sixteen wards, has a good water-supply, the works being owned by the city, is paved with asphalt, cobble-stones, and macadam, is sewered, and has a steam heating plant. Reading is an important manufacturing centre, especially of iron and steel. In 1900 it contained 843 manufacturing establishments, with a total capital of $27,975,628. These employed 12,165 hands, and the product was valued at $36,902,511. Iron and steel goods were valued at $9,530,286, hardware at $1,611,268, and foundry and machine-shop products at $2,437,355, and cars and general shop construction and repairs at $6,315,128. Tobacco and cigars had a value of $1,683,466, fur hats, $1,133,688, and hosiery and knitted goods, $1,326,397. Reading contains also the principal workshops of the Philadelphia and Reading Railway Company. In 1899 the assessed valuation of real and personal property was $43,480,679, the net debt of the city was $1,371,567, and the rate of taxation was $14·50 per $1000. Population (1890), 58,661; (1900), 78,961, of whom 5940 were foreign-born and 534 negroes.

Rechberg und Rothenloewen, Johann Bernard, Count von (1809–1899), Austrian statesman, sprang from a noble family which from the 12th century has held a prominent position in Swabia. At the time of the Revolution the fief had been divided between the modern kingdoms of Bavaria and Würtemberg, and his father, Count Aloys (1766–1849), was one of the foremost Bavarian statesmen during the first quarter of the 19th century, and took a great part at the celebrated Carlsbad Conferences. Count Johann, who was the second son, was destined for the Bavarian public service, his elder brother being a hereditary member of the Upper House in the Parliament of Würtemberg. He was educated at the universities of Strasburg and Munich, but the part he took as second in a duel brought upon him the displeasure of King Ludwig, and at the age of twenty he transferred himself to the Austrian service. After holding various inferior diplomatic appointments, he was in 1843 sent as envoy to Brazil. He returned to Europe in 1847, and on the outbreak of the revolution in 1848 was of great service to Prince Metternich, whom he accompanied and assisted when, deserted by all his former friends, the aged statesman had to fly from Austria to England. In 1853 he was appointed civil coadjutor to Radetzky, who was governor of the Lombardo-Venetian kingdom—a very difficult post, owing to the jealousy with which he was regarded by the army. In 1855 he was made Austrian representative at, and president of, the Germanic diet at Frankfort. As a pupil of Metternich he would have wished to preserve the good understanding with Prussia which seemed the necessary foundation for a conservative policy; he was, however, made the instrument for the anti-Prussian policy of Buol; this brought about constant disputes with Bismarck, at that time Prussian envoy at the Diet, which were sharpened by Rechberg's choleric temper, and on one occasion nearly led to a duel. Bismarck, however, both in his despatches and his memoirs, always expressed a high appreciation of his character and abilities. In May 1859, on the eve of the war with France and Sardinia, Rechberg was chosen to succeed Buol as foreign minister. This post he held for five of the most eventful years of Austrian history. After the defeat of Magenta he accompanied the emperor to Italy, and he had to meet the crisis caused by a war for which he was not responsible. He began the concessions to Hungary, but the chief influence in the Council soon passed to colleagues, especially Schmerling, with whose policy he was not in agreement. His attempts to establish a good understanding with Prussia were constantly frustrated, and in 1863 he offered his resignation as a protest against the Furstentag at Frankfort, which had been decided on without his knowledge. The emperor refused to accept his resignation, and, unfortunately for his own reputation, he did not insist on it, for it was the inconsistent and variable policy arising from the conflicting aims of different ministers which brought so many disasters on Austria. Rechberg succeeded, indeed, in establishing a close co-operation with Prussia in regard to the Elbe duchies; but this was very unpopular in Austria, where it was said he had been made the dupe of Bismarck. He still hoped to establish a firm and permanent alliance with Prussia, but for this he had not sufficient influence, either in his own ministry or at Berlin; and when his proposals for a customs union were rejected by the Prussian ministry, his fall was inevitable. He resigned in October 1864, foretelling the speedy outbreak of a war which he had long striven to avert, and for which he saw that Austria was not strong enough. From this time he lived in complete retirement till his death, which took place at his country house at Schwechat in 1899.

See also an article by Friedjung in *Bettelman's Biographische Jahrbucher*, Berlin, 1900; also *Der Kampf um die Vorherrschaft in Deutschland*, Stuttgart, 1898, by the same author.—Sybel. *Die Begründung des deutschen Reiches* and Bismarck's *Reflections and Reminiscences*. (J. W. He.)

Recklinghausen, a town of Prussia, province of Westphalia, 22 miles by rail north-west of Dortmund, with coal-mines, limestone quarries, brick-works, and manufacture of linen, lamp-wicks, and tobacco, saw-mills and distilleries. Population (1885), 9199; (1900), 34,042.

Reclus, Jean Jacques Elisée (1830–——), French geographer, was born at Sainte-Foy la Grande (Gironde), on 15th March 1830. He was the second son of a Protestant pastor, who had a family of twelve children, several of whom have also acquired some celebrity either as men of letters, politicians, or members of the learned professions. His education, begun in Rhenish Prussia, was continued in the Protestant College of Montauban, and completed at the University of Berlin, where he followed a long course of geography under Karl Ritter. Withdrawing from France in consequence of the events of December 1851, he spent the next six years (1852–57) visiting the British Isles, the United States, Central America, and Colombia, losing no opportunity of studying the physical features and economic conditions of these lands, and acquiring a practical knowledge of English, Spanish, and several other European languages. On his return to Paris he contributed to the *Revue des Deux Mondes*, to the *Tour du Monde* and other serials, a large number of articles embodying the results of his geographical work. During the siege of Paris, Reclus shared in the aerostatic operations conducted by M. Nadar, and also served in the National Guard, while as a member of the Association Nationale des Travailleurs he published in the *Cri du Peuple* a hostile manifesto against the Government of Versailles in connexion with the Communist rising of 18th March 1871. Continuing to serve in the National Guard, now in open revolt, he was taken prisoner on 5th April, and on 16th November sentenced to transportation for life; but, largely at the instance of influential deputations from England, the sentence was commuted in January 1872 to perpetual banishment. Thereupon, after a short visit to Italy, he settled at Clarens, in Switzerland, where he resumed his literary labours, and wrote nearly the whole of his great work, *La Nouvelle Géographie Universelle, La Terre et les Hommes*, 19 vols. (1875–94), a stupendous compilation, profusely illustrated with maps, plans, and engravings, and crowned with the gold medal of the Paris Geographical Society in 1892. An English edition appeared simultaneously, also in 19 vols., the first four by E. G. Ravenstein, the rest by A. H. Keane. A preliminary work, entitled *La Terre, Description des Phénomènes de la Vie du Globe*, 2 vols., had already appeared in 1867–68, the two forming the most comprehensive geographical series ever issued in any language. Extreme accuracy and brilliant exposition form the leading characteristics of these, as of all the author's writings, which thus possess permanent literary and scientific value. In 1882 M. Reclus initiated the "Anti-Marriage Movement," in accordance with which he allowed his two daughters to marry without any civil or religious sanction whatever. This step caused no little embarrassment to many of his well-wishers, and was followed by Government prosecutions, instituted in the High Court of Lyons, against the anarchists, members of the International Association, of which M. Reclus and Prince Kropotkin were designated as the two chief organizers. The Russian socialist was arrested and condemned to five years' imprisonment, but M. Reclus, being resident in Switzerland, escaped the arm of French justice. After 1892 he filled the chair of comparative geography in the University of Brussels, and contributed several important memoirs to French, German, and English scientific journals. Amongst these may be mentioned "The Progress of Mankind" (*Contemp. Rev.*, 1896); "Attila de Gerando" (*Rev. Géograph.*, 1898); "A Great Globe" (*Geograph. Journ.*, 1898); "L'Extrême-Orient" (*Bul. Antwerp Geo. Soc.*, 1898), a thoughtful study of the political geography of the Far East and its possible changes; "La Perse" (*Bul. Soc. Neuchateloise*, 1899); "La Phénicie et les Phéniciens" (*ibid.*, 1900); *La Chine et la Diplomatie européenne* ("L'Humanité Nouvelle" series, 1900); *L'Enseignement de la Géographie* (Instit. Géograph. de Bruxelles, No. 5, 1901).

Red Bank, a town of Monmouth county, New Jersey, U.S.A. It is at the head of navigation of the Shrewsbury river, on the Central of New Jersey and the Pennsylvania railways, in the eastern part of the state. Population (1890), 4145; (1900), 5428, of whom 508 were foreign-born and 620 negroes.

Redcar, a watering-place and parish in the North Riding of Yorkshire, England, in the Cleveland parliamentary division, 8 miles north-east of Middlesbrough, with a station on a branch of the North-Eastern Railway. Its long range (from Tees to Saltburn, a distance of 10 miles) of firm sands has made it a popular summer resort. Race meetings are held on the racecourse here on Whitsun Monday and Tuesday, and in August. Since 1894 the town has been governed by an urban district council. Population of the parish and urban district (1891), 2818. Population of area, extended in 1898 to include Coatham parish (1901), 7695.

Redditch, a town and parish in the county of Worcester, England, in the Eastern parliamentary division of the county, 16 miles south-west of Birmingham by railway. The church of St Stephen was restored in 1894. Other places of worship have been rebuilt or enlarged. The Smallwood Hospital was erected in 1895, and the Smallwood Almshouses in 1897. Redditch is the centre of a district noted for its needles and fishhooks. The division of labour in the production of needles necessitates each passing through nearly twenty pairs of hands. Population of urban district (1891), 11,311; (1901), 13,493.

Redgrave, Richard (1801–1888), English artist, was born at Pimlico on 30th April 1801, and worked at first as a designer. He became a student in the Royal Academy Schools in 1826, and was elected an Associate in 1840 and an Academician in 1851 (retired, 1882). His "Gulliver on the Farmer's Table" (1837) made his reputation as a painter. He began in 1847 a connexion with the Government Art Schools which lasted for a long term of years, and among other posts he held those of inspector-general of art in the Science and Art Department, and art director of the South Kensington Museum. He was greatly instrumental in the establishment of this institution, and he claimed the credit of having secured the Sheepshanks and Ellison gifts for the nation. He was also surveyor of the Royal Pictures. He was offered, but declined, a knighthood in 1869. Redgrave was an assiduous painter of landscape and *genre*; his best pictures being "Country Cousins" (1848) and "The Return of Olivia" (1848), both in the national collection, "The Sempstress" (1844), "Well Spring in the Forest" (1865). He died on 14th December 1888.

See F. M. REDGRAVE, *Richard Redgrave, C.B., R.A.: A Memoir, compiled from his Diary*. London, 1891.

Redon, chief town of arrondissement, department of Ille-et-Vilaine, France, 40 miles south-south west of Rennes, on railway from Savenay to Landerneau, on the right bank of the Vilaine above the confluence of the Oust, and on the canal from Nantes to Brest. The church of St Sauveur, formerly abbatial, has a fine 14th-century belfry with spire, and a plain 14th-century square tower, with rounded angles. The choir, with deambulatory and radiating

chapels, forms one of the most remarkable ecclesiastical buildings of the 13th century in Brittany. One of the ancient tombs, partly destroyed during the Revolution, is supposed to be that of Francis I. The abbey has been converted into an ecclesiastical college. Some 16th-century timbered houses have interesting carvings. French emery is manufactured on an extensive scale, and plate powder, coal-tar, agricultural implements, and tanning represent other branches of industry. The port is accessible, at high tides, for vessels of 600 to 700 tons, and a line of railway connects the quays with the station. The port traffic, exclusive of coasting, amounted in 1900 to 12,529 tons, of which 12,147 tons were carried in British vessels. Including coasting trade, the total movement was 18,295 tons. Population (1886), 4847; (1896), 5599.

Redonda. See ANTIGUA.

Redondela, a town of Spain, province of Pontevedra, to the north-east of Vigo, in a bend of the estuary of that name; it is a station on the Orense Vigo and Pontevedra lines. Population, 11,399 in 1887 and 10,966 in 1897. The river is only accessible for small coasting vessels. The town has a fine square, regular clean streets, markets, a casino, convents, and interesting parish church. The railway viaducts are fine structures, running actually over the town. In the neighbourhood are ruins of several feudal castles, and the fine hall of Marquess Vega de Armijo.

Redruth, a market-town and urban district, Cornwall, England, in the Camborne parliamentary division, about 9 miles west of Truro by rail. This is the chief mining town of the county, and the bulk of its population is engaged in the tin mines or at the numerous tin-streaming works. Among modern public buildings are a mining exchange (1880), science and art school (1883), Liberal hall (1886), and Primitive Methodist chapel (1888). In 1895 Mr Passmore Edwards erected a public free library, at a cost of £2000. Population of the urban district (1881), 9335; (1901), 10,451.

Red Sea.—The Red Sea is a narrow strip of water extending south-south-east from Suez to the Strait of Bab-el-Mandeb in a nearly straight line, and separating the coasts of Arabia from those of Egypt, Nubia, and Abyssinia. Its total length is about 1200 miles, and its breadth varies from about 250 miles in the southern half to 130 miles in 27° 45′ N., where it divides into two parts, the Gulf of Suez and the Gulf of Akaba, separated from each other by the peninsula of Sinai.

Depths.

The Gulf of Suez is shallow, and slopes regularly down to the northern extremity of the Red Sea basin, which has a maximum depth of 640 fathoms, and then over a shoal of 60 fathoms goes down to 1200 fathoms in 22° 7′ N. The Gulf of Akaba is separated from the Red Sea by a submarine bank only 70 fathoms from the surface, and in 28° 39′ N. and 34° 43′ E. it attains the considerable depth of 700 fathoms. South of the 1200-fathom depression a ridge rises to 500 fathoms in the latitude of Jedda, and south of this again a similar depression goes down to 1190 fathoms. Throughout this northern part, *i.e.*, to the banks of Suakin and Farisan in 20° N., the 100-fathom line keeps to a belt of coral reef close inshore, but in lower latitudes the shallow coral region, 300 miles long and 70 to 80 miles across, extends farther and farther seaward, until in the latitude of Hodeida the deep channel (marked by the 100-fathom line) is only 20 miles broad, all the rest of the area being dangerous to navigation, even for small vessels. In the middle of the gradually narrowing channel three depressions are known to exist; soundings in two of these are: 1110 fathoms in 20° N. and 890 fathoms in 16° N., a little to the north of Massawa. To the north-west of the volcanic island of Zebayir the depth is less than 500 fathoms; the bottom of the channel rises to the 100-fathom line at Hanish Island (also volcanic), then shoals to 45 fathoms, and sinks again in about the latitude of Mocha in a narrow channel which curves westward round the island of Perim (depth 170 fathoms), to lose itself in the Indian Ocean. This western channel is 16 miles wide in the Strait of Bab-el-Mandeb; the eastern channel of the strait is 2 miles broad and 16 fathoms deep.

Area, volume, and mean depth.

Murray estimates the total area at 158,750 square miles, and its volume at 67,700 cubic miles, giving a mean depth of 375 fathoms. Karstens gives the area at 448,810 square kilometres (130,424 square geographical miles) and the volume at 206,901 cubic kilometres (32,413 cubic geographical miles), which gives a mean depth of 252 fathoms. Both these computations, however, were made before the date of the Austrian exploring expeditions (1896–98). Bludau's measurements give the total area draining to the Red Sea at about 255,000 square geographical miles.

Formation.

The Red Sea is formed by a line of fracture, probably dating from Pliocene times, crossing the centre of a dome of Archæan rocks, on both flanks of which, in Egypt and Arabia, rest Secondary and Tertiary deposits. The granite rocks forming the core of the dome appear at the surface on the Red Sea coast, at the western end of the transverse line of heights crossing El Nejed (see ARABIA). Along the line of fracture traces of volcanic activity are frequent; a group of volcanic islands occurs in 14° N., and on Jebel Teir, farther north, a volcano has only recently become extinct. The margin of the Red Sea itself consists, on the Arabian side, of a strip of low plain backed by ranges of barren hills of coral and sand formation, and here and there by mountains of considerable height. The greater elevations are for the most part formed of limestones, except in the south, where they are largely volcanic. The coasts of the Gulf of Akaba are steep, with numerous coral reefs on both sides. On the African side there are in the north wide stretches of desert plain, which towards the south rise to elevated tablelands, and ultimately to the mountains of Abyssinia. The shores of the Red Sea are little indented; good harbours are almost wanting in the desert regions of the north, while in the south the chief inlets are at Massawa, and at Kamaran, almost directly opposite. Coral formations are abundant; immense reefs, both barrier and fringing, skirt both coasts, often enclosing wide channels between the reef and the land. The reefs on the eastern side are the more extensive; they occur in places as much as 25 miles from the land. It has long been known that the whole Red Sea area is undergoing gradual elevation, and much has been done in recent years in investigating the levels of raised beaches found in different localities, but our knowledge is not yet sufficiently complete to justify general statements as to the nature and progress of these movements.

Meteorology.

In the northern part, down to almost 19° N., the prevailing winds are north and north-west. The middle region, to 14°–16° N., has variable winds in an area of low barometric pressure, while in the southern Red Sea south-east and east winds prevail. From June to August the north-west wind blows over the entire area; in September it retreats again as far as 16° N., south of which the winds are for a time variable. In the Gulf of Suez the westerly, or "Egyptian," wind occurs frequently during winter, sometimes blowing with violence, and generally accompanied by fog and clouds of dust. Strong north-north-east winds prevail in the Gulf of Akaba during the greater part of the year; they are weakest in April and May, sometimes giving place at that season to southerly breezes. During fine weather and near the coasts, land and sea breezes are met with in all latitudes—in some places strongly developed. The high temperature and great relative humidity make the summer climate of the Red Sea one of the most disagreeable in the world.

Temperature.

The mean annual temperature of the surface waters near the head is 77° F.; it rises to 80° in about 22° N., to 84° in 16° N., and drops again to 82° at the Strait of Bab-el-Mandeb. Daily variations of temperature are observable to a depth of over 50 fathoms. Temperature is, on the whole, higher near the Arabian than the Egyptian side, but it everywhere diminishes with increase of depth and latitude, down to 380 fathoms from the surface; below this depth a uniform constant temperature of 70·7° F. is observed throughout. In the Gulf of Suez temperature is relatively low,

falling rapidly from south to north. The waters of the Gulf of Akaba are warmer towards the Arabian than the Sinai coasts; a uniform temperature of 70·2° is observed at all depths below 270 fathoms.

Salinity.

The salinity of the waters is relatively great, the highest recorded being 42·7 per mille (Gulf of Suez), and the lowest 36·2 (Perim harbour). The distribution is, speaking generally, the opposite to that of temperature; salinity increases from the surface downwards, and from the south northwards, and it is greater towards the western than the eastern side. This statement holds good for the Gulf of Suez, in which the water is much salter than in the open sea; but in the Gulf of Akaba the distribution is exceedingly uniform, nowhere differing much from an average of 40·6 per mille.

Circulation.

The movements of the waters are of great irregularity and complexity, rendering navigation difficult and dangerous. Two features stand out with special distinctness: the exchange of water between the Red Sea and the Indian Ocean, and the tidal streams of the Gulf of Suez. From the observations of salinity it is inferred that a surface current flows inwards to the Red Sea in the eastern channel of the Strait of Bab-el-Mandeb, while a current of very salt water flows outward to the Indian Ocean, through the western channel, at a depth of 50 to 100 fathoms from the surface. In the Gulfs of Suez and Akaba, almost the only part of the Red Sea in which tidal phenomena are well developed, a sharply defined tidal circulation is found. Elsewhere the surface movements at least are controlled by the prevailing winds, which give rise in places to complex "transverse" currents, and near the coasts are modified by the channels enclosed by the coral reefs. During the prevalence of the north and north-west winds the surface level of the northern part of the Red Sea is depressed by as much as 2 feet. The great evaporation going on from the surface probably causes a slow vertical circulation in the depth, the salter colder waters sinking, and ultimately escaping to the Indian Ocean. Extensive collections of the deposits forming the bed were made by the expeditions of the Austrian ship *Pola* (1896 and 1898). These have been subjected to analysis by Dr K. Natterer, whose conclusions, however, have been disputed by a number of other investigators. The detailed reports on the zoological collections of the *Pola* expeditions have not yet been published, but their examination has already shown that certain well-defined districts are extremely rich in plankton, while others are correspondingly poor; and it appears that the latter occur in districts surrounded by currents of relatively low temperature, while the richer parts are where the movements of water are blocked by irregularities in the coast-line.

Red Wing, a city of Minnesota, U.S.A., capital of Goodhue county. It is on the west bank of the Mississippi, at the head of Lake Pepin, in the south-eastern part of the state, at an altitude of 685 feet. It is irregularly laid out, and has a water-supply and sewerage system. It is on the Chicago, Milwaukee, and St Paul, the Duluth, Red Wing, and Southern, and the Chicago Great Western railways. It contains lumber and flour mills, furniture factories, and other industries. It is an important shipping point for grain. Population (1890), 6294; (1900), 7525, of whom 2154 were foreign-born.

Reed, Thomas Brackett (1839- ——), American lawyer and statesman, was born at Portland, Maine, 18th October 1839. He graduated from Bowdoin College, and practised law in his native state. A Republican in politics, he served in the legislature and in other capacities in the state, and in 1876 was elected to the National House of Representatives, where he remained continuously till his voluntary withdrawal from public life in 1899. In 1885 he was formally recognized as the leader of his party in the House, and in 1889, 1895, and 1897 he was elected Speaker. His most conspicuous achievement was the modification of the procedure of the House so as to facilitate legislation. Despite violent opposition, he forced through in 1890 a rule under which "constructive absence" (*i.e.*, the mere refusal to vote) cannot be employed to break a quorum. The firm, and even arbitrary, measures he used to prevent filibustering caused him to be designated popularly as the "Czar." Upon his retirement from public life he took up the practice of law in New York City.

Reeve, Henry (1813–1895), English publicist, younger son of a well-known Whig physician and writer of Norwich, and nephew of Mrs Sarah Austin, was born at Norwich on 9th September 1813, and educated at the grammar school there under Edward Valpy. During his holidays he saw a good deal of the young John Stuart Mill. In 1829 he studied at Geneva and mixed in Genevese society, then very brilliant, and including the Sismondis, Huber, Bonstetten, De Candolle, Rossi, Krasinski (his most intimate friend), and Mickiewicz, whose *Faris* he translated. During a visit to London in 1831 he was introduced to Thackeray and Carlyle, while through the Austins he made the acquaintance of other men of letters. Next year he was *lancé* in Paris, meeting Victor Hugo, Cousin, and Scott. He travelled in Italy, sat under Schelling at Munich and under Tieck at Dresden, became in 1835–36 a frequenter of Madame de Circourt's salon, and numbered among his friends and acquaintances Lamartine, Lacordaire, De Vigny, Thiers, Guizot, Montalembert, and De Tocqueville, of whose books, *Démocratie en Amérique* and the *Ancien Régime*, he made standard translations into English. In 1837 he was made clerk of appeal and then registrar to the judicial committee of the Privy Council. From 1840 to 1855 he "exhaled his soul" in newspaper articles, mainly for *The Times*, his close touch with men like Guizot, Bunsen, Lord Clarendon, and his own chief at the Privy Council Office, Charles Greville, enabling him to write with authority on foreign policy during the critical period from 1848 to the end of the Crimean War. His services assisted largely in making *The Times* the most authoritative exponent of international policy among the journals of Europe. Reeve calculated that he wrote between two and three thousand articles for this paper alone, and received over thirteen thousand pounds for them. Upon the promotion of Sir George Cornewall Lewis to the Cabinet early in 1855, Reeve was asked by Longman to edit the April number of the *Edinburgh Review*, to which his father had been one of the earliest contributors, and in the following July he became the editor. He soon abandoned daily journalism. He had already been an occasional contributor both to the *Quarterly* and to the *Edinburgh Review*, and he maintained the Whig traditions of the latter for over forty years with undeviating loyalty. His friendship with the Orleanist leaders in France survived all vicissitudes, but he was appealed to for guidance by successive French ambassadors, and was more than once the medium of private negotiations between the English and French Governments. In April 1863 he published what was perhaps the most important of his contributions to the *Edinburgh*—a searching review of Kinglake's *Crimea*; and in 1872 he brought out a selection of his *Quarterly* and *Edinburgh* articles on eminent Frenchmen, entitled *Royal and Republican France.* Three years later appeared the first of three instalments (1875, 1885, and 1887) of his edition of the famous *Memoirs* which Charles Greville had placed in his hands a few hours before his death in 1865. A purist in point of form and style, of the school of Macaulay and Milman, Reeve outlived his literary generation: he had little in common with the views of Carlyle, Ruskin,

Morris, Darwin, and Spencer, and he became eventually one of the most reactionary of old Whigs. Yet he continued to edit and upon the whole to maintain the reputation of the *Edinburgh* until his death, which took place at his seat of Foxholes, in Hants, on 21st October 1895. He had been elected a member of "The Club" in 1861, and was made a D.C.L. by Oxford University in 1869, a C.B. in 1871, and a corresponding member of the French Institut in 1865. A striking panegyric was pronounced upon him by his lifelong friend, the Duc d'Aumale, before the Académie des Sciences in November 1895. His *Memoirs and Letters* (2 vols., with portrait) were admirably edited by Prof. J. K. Laughton in 1898.

(T. SE.)

Reeves, John Sims (1818–1900), English vocalist, was born at Woolwich, 26th September 1818, and received his musical education from his father, a musician in the Royal Artillery. At the age of fourteen he had progressed so far as to be appointed organist of North Cray church, and could play the oboe, bassoon, violin, and violoncello. In spite of these various musical gifts, he seems to have studied medicine for a year, but changed his mind when he gained his adult voice: it was at first a baritone, and he made his earliest appearance at Newcastle in 1839 in various baritone parts. He studied with Hobbs and T. Cooke, and, his voice having become a tenor, he appeared under Macready's management at Drury Lane (1841–43) in subordinate tenor parts in Purcell's *King Arthur*, *Der Freischütz*, and *Acis and Galatea*, when Handel's pastoral was mounted on the stage with Stanfield's scenery. Four years were spent in study on the Continent, under Bordogni in Paris and Mazzucato in Milan, and his début in Italian opera was made at the Scala as Edgardo in *Lucia*. He reappeared in London in May 1847, at a benefit concert for Vincent Wallace, and at one of the Ancient Concerts in the following month, his career on the English operatic stage beginning at Drury Lane in December 1847 in *Lucia*, under the conductorship of Hector Berlioz. In Balfe's *Maid of Honour* he created the part of Lyonnel in the same season. In 1848 he went to Her Majesty's Theatre, singing in *Linda di Chamounix*; and in the autumn of that year, at the Norwich Festival, made a great sensation in "The enemy said," from *Israel in Egypt*, a song with which he was identified for many years, and in which the finest qualities of his ringing voice could be appreciated. From his first appearance at the Sacred Harmonic Society in the following November he was recognized as the leading English tenor; and in the stock oratorios, as well as in Costa's *Eli* and *Naaman*, the tenor parts in both of which were written for him, his great artistic gifts were at once recognized by the public. His first Handel Festival was that of 1857, and the effect of his wonderful declamation in the Crystal Palace was a main attraction of this and of many subsequent festivals. His retirement from public life, at first announced as to take place in 1882, did not actually occur till 1891, when a farewell concert for his benefit was given at the Albert Hall. His savings were invested in an unfortunate speculation, and he was compelled to reappear in public for a number of years. As a lesson in the art of declaiming words, even after his voice had become a mere thread, these appearances were valuable to young singers, but they had little or no musical significance; and that they did not lower the prestige he enjoyed for so long is a testimony to the power he had formerly exercised. He died at Worthing, 25th October 1900. (J. A. F. M.)

Reformed Episcopal Church, The, a small community, with branches in the United States, Great Britain, and Canada, was established in 1873 by Dr Cummins, who had just resigned his office as assistant-bishop of Kentucky in the Protestant Episcopal Church in the United States. Dr Cummins (then canonically under suspension and unable to perform any episcopal act) consecrated a bishop to assist him, and through this succession the Reformed Episcopal Church claims to derive historically valid orders. Its supreme authority is vested in a General Synod, in which the laity are represented. Each congregation is self-governing. The distinguishing characteristics of the Church are indicated in its revised version of the English Prayer-Book, in which everything that might be construed as "sacerdotal" is eliminated. In Great Britain and Canada it is reported that there are 35 congregations, with 2200 communicants, and in the United States 92 congregations, with 9500 communicants.

Refrigerating and Ice-Making Machinery.—Refrigeration is the cooling of a body by the transfer of a portion of its heat to another and therefore a cooler body. For ordinary temperatures it is performed directly with water as the cooling agent, especially when well water, which usually has a temperature of from 52° to 55° Fahr., can be obtained. There are, however, an increasingly large number of cases in which temperatures below that of any available natural cooling agent are required, and in these it is necessary to resort to machines which are capable of producing the required cooling effect by taking in heat at low temperatures and rejecting it at temperatures somewhat above that of the natural cooling agent, which for obvious reasons is generally water. The function of a refrigerating machine, therefore, is to abstract heat at a low temperature and reject it at a higher one.

This involves the expenditure of a quantity of work W, the amount in any particular case being found by the equation $W = Q_2 - Q_1$, where W is the work, expressed by its equivalent in British thermal units; Q_2 the quantity of heat, also in B.T.U., given out at the higher temperature T_2; and Q_1 the heat taken in at the lower temperature T_1. It is evident that the discharged heat Q_2 is equal to the abstracted heat Q_1, plus the work expended, seeing that the work W, which causes the rise in temperature from T_1 to T_2, is the thermal equivalent of the energy actually expended in raising the temperature to the level at which it is rejected. The relation then between the work expended and the actual cooling work performed denotes the efficiency of the process, and this is expressed by $\frac{Q_1}{Q_2 - Q_1}$; but as in a perfect refrigerating machine it is understood that the whole of the heat Q_1 is taken in at the absolute temperature T_1, and the whole of the heat Q_2 is rejected at the absolute temperature T_2, the heat quantities are proportional to the temperatures, and the expression $\frac{T_1}{T_2 - T_1}$ gives the ideal coefficient of performance for any stated temperature range, whatever working substance is used. These coefficients for a number of cases met with in practice are given in the following table. They show

TABLE I.

30°	24·5	16·3	12·2	9·8	8·2	7·0
40°	50·0	25·0	16·7	12·5	10·0	8·3

that in all cases the heat extracted exceeds by many times the heat expended. As an instance, when heat is taken in at 0° and

falling rapidly from south to north. The waters of the Gulf of Akaba are warmer towards the Arabian than the Sinai coasts; a uniform temperature of 70·2° is observed at all depths below 270 fathoms.

Salinity. The salinity of the waters is relatively great, the highest recorded being 42·7 per mille (Gulf of Suez), and the lowest 36·2 (Perim harbour). The distribution is, speaking generally, the opposite to that of temperature; salinity increases from the surface downwards, and from the south northwards, and it is greater towards the western than the eastern side. This statement holds good for the Gulf of Suez, in which the water is much salter than in the open sea; but in the Gulf of Akaba the distribution is exceedingly uniform, nowhere differing much from an average of 40·6 per mille.

Circulation. The movements of the waters are of great irregularity and complexity, rendering navigation difficult and dangerous. Two features stand out with special distinctness: the exchange of water between the Red Sea and the Indian Ocean, and the tidal streams of the Gulf of Suez. From the observations of salinity it is inferred that a surface current flows inwards to the Red Sea in the eastern channel of the Strait of Bab-el-Mandeb, while a current of very salt water flows outward to the Indian Ocean, through the western channel, at a depth of 50 to 100 fathoms from the surface. In the Gulfs of Suez and Akaba, almost the only part of the Red Sea in which tidal phenomena are well developed, a sharply defined tidal circulation is found. Elsewhere the surface movements at least are controlled by the prevailing winds, which give rise in places to complex "transverse" currents, and near the coasts are modified by the channels enclosed by the coral reefs. During the prevalence of the north and north-west winds the surface level of the northern part of the Red Sea is depressed by as much as 2 feet. The great evaporation going on from the surface probably causes a slow vertical circulation in the depth, the salter colder waters sinking, and ultimately escaping to the Indian Ocean. Extensive collections of the deposits forming the bed were made by the expeditions of the Austrian ship *Pola* (1896 and 1898). These have been subjected to analysis by Dr K. Natterer, whose conclusions, however, have been disputed by a number of other investigators. The detailed reports on the zoological collections of the *Pola* expeditions have not yet been published, but their examination has already shown that certain well-defined districts are extremely rich in plankton, while others are correspondingly poor; and it appears that the latter occur in districts surrounded by currents of relatively low temperature, while the richer parts are where the movements of water are blocked by irregularities in the coast-line.

Refrigerating and Ice-Making Machinery.—Refrigeration is the cooling of a body by the transfer of a portion of its heat to another and therefore a cooler body. For ordinary temperatures it is performed directly with water as the cooling agent, especially when well water, which usually has a temperature of from 52° to 55° Fahr., can be obtained. There are, however, an increasingly large number of cases in which temperatures below that of any available natural cooling agent are required, and in these it is necessary to resort to machines which are capable of producing the required cooling effect by taking in heat at low temperatures and rejecting it at temperatures somewhat above that of the natural cooling agent, which for obvious reasons is generally water. The function of a refrigerating machine, therefore, is to abstract heat at a low temperature and reject it at a higher one.

This involves the expenditure of a quantity of work W, the amount in any particular case being found by the equation $W = Q_2 - Q_1$, where W is the work, expressed by its equivalent in British thermal units; Q_2 the quantity of heat, also in B.T.U., given out at the higher temperature T_2; and Q_1 the heat taken in at the lower temperature T_1. It is evident that the discharged heat Q_2 is equal to the abstracted heat Q_1, plus the work expended, seeing that the work W, which causes the rise in temperature from T_1 to T_2, is the thermal equivalent of the energy actually expended in raising the temperature to the level at which it is rejected. The relation then between the work expended and the actual cooling work performed denotes the efficiency of the process, and this is expressed by $\frac{Q_1}{Q_2 - Q_1}$; but as in a perfect refrigerating machine it is understood that the whole of the heat Q_1 is taken in at the absolute temperature T_1, and the whole of the heat Q_2 is rejected at the absolute temperature T_2, the heat quantities are proportional to the temperatures, and the expression $\frac{T_1}{T_2 - T_1}$ gives the ideal coefficient of performance for any stated temperature range, whatever working substance is used. These coefficients for a number of cases met with in practice are given in the following table. They show that in all cases the heat extracted exceeds by many times the heat expended. As an instance, when heat is taken in at 0° and

TABLE I.

T_1. Temperature at which Heat is extracted in Degrees Fahr.	T_2. Temperature at which Heat is rejected in Degrees Fahr.					
	50°.	60°.	70°.	80°.	90°.	100°.
−10°	7·5	6·4	5·6	5·0	4·5	4·1
0°	9·2	7·7	6·6	5·8	5·1	4·6
10°	11·7	9·4	7·8	6·7	5·9	5·2
20°	16·0	12·0	9·6	8·0	6·8	6·0
30°	24·5	16·3	12·2	9·8	8·2	7·0
40°	50·0	25·0	16·7	12·5	10·0	8·3

rejected at 70°, a perfect refrigerating machine would abstract 6·6 times as much heat as the equivalent of the energy to be applied. If, however, the heat is to be rejected at 100°, then the coefficient is reduced to 4·6.

By examining Table I. it will be seen how important it is to reduce the temperature range as much as possible, in order to obtain the most economical results. No actual refrigerating machine does, in fact, take in heat at the exact temperature of the body to be cooled and reject it at the exact temperature of the cooling water, but, for economy in working, it is of great importance that the differences should be as small as possible.

There are two distinct classes of machines used for refrigerating and ice-making. In the first refrigeration is produced by the expansion of atmospheric air, and in the second by the evaporation of a more or less volatile liquid.

Compressed-air Machines.—A compressed-air refrigerating machine consists in its simplest form of three essential parts—a compressor, a compressed-air cooler, and an expansion cylinder. It is shown diagrammatically in Fig. 1 in connexion with a chamber which it is keeping cool. The compressor compresses air from the room, the work it expends

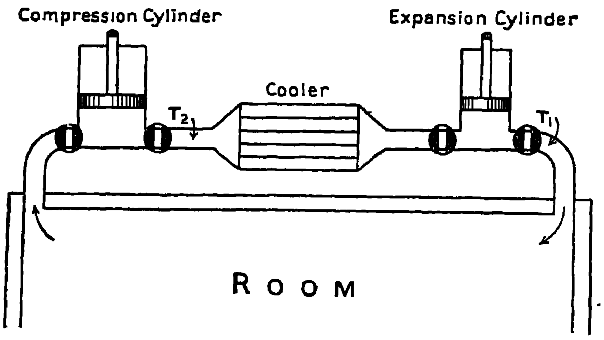

Fig. 1.—Compressed-Air Refrigerating Machine.

being converted into heat. The compressed air, leaving the compressor at the temperature T_2, passes through the cooler, where it is cooled by means of water, and then is admitted to the expansion cylinder, where it is expanded, performing work on the piston, to atmospheric pressure. The heat equivalent of the mechanical work performed on the piston is abstracted from the air, which is discharged at the temperature T_1. This temperature T_1 is necessarily very much below the temperature to be maintained in the room, because the cooling effect is produced by transferring heat from the room or its contents to the air, which is thereby heated. The rise in temperature of the air in its passage through the room is, in fact, the measure of the cooling effect produced. If such a machine could be constructed with reasonable mechanical efficiency to compress the air to a temperature but slightly above that of the cooling water, and to expand the air to a temperature but slightly below that required to be maintained in the room, we should of course get a result approximating in efficiency somewhat nearly to the figures given in Table I. Unfortunately, however, such results cannot be obtained in practice, because the extreme lightness of the air and its very small heat capacity (which at constant pressure is ·2379) would necessitate the employment of a great volume, with extremely large and mechanically inefficient cylinders and apparatus. A pound of air, representing about 12 cubic feet, if raised 10° Fahr. will only take up about 2·4 B.T.U. Consequently to make such a machine mechanically successful a comparatively small weight of air must be used, and the temperature difference increased; in other words, the air is discharged at a temperature very much below that to be maintained in the room.

This theory of working is founded on the Carnot cycle for a perfect heat motor, a perfect refrigerating machine being simply a reversed heat motor. Another theory involves the use of the Stirling regenerator, which, as is well known, was proposed in connexion with the Stirling heat engine. The air machine invented by Dr A. Kirk in 1862, and described by him in a paper on the "Mechanical Production of Cold" (*Proc. Inst. C.E.* vol. xxxvii. 1874, p. 244), is simply a reversed Stirling air engine, the air working in a closed cycle instead of being actually discharged into the room to be cooled, as is the usual practice with ordinary compressed-air machines. Kirk's machine was used commercially with success on a fairly large scale, chiefly for ice-making, and it is recorded that it produced about 4 ℔ of ice for 1 ℔ of coal. In 1868 Mr J. Davy Postle read a paper before the Royal Society of Victoria, suggesting the conveyance of meat on board ship in a frozen state by means of refrigerated air, and in 1869 he showed by experiment how it could be done; but his apparatus was not commercially developed. In 1877 a compressed-air machine was designed by Mr J. J. Coleman of Glasgow, and in the early part of 1879 one of his machines was fitted on board the Anchor liner *Circassia*, which successfully brought a cargo of chilled beef from America—the first imported by the aid of refrigerating machinery, ice having been previously used. The first successful cargo of frozen mutton from Australia was also brought by a Bell-Coleman machine in 1879, and from this period the practical application of refrigerating machinery in this country received a great impetus. In the Bell-Coleman machine the air was cooled during compression by means of an injection of water, and further by being brought into contact with a shower of water. Another, perhaps the principal, feature was the interchanger, an apparatus whereby the compressed air was further cooled before expansion by means of the comparatively cold air from the room in its passage to the compressor, the same air being used over and over again. The object of this interchanger was not only to cool the compressed air before expansion, but to condense part of the moisture in it, so reducing the quantity of ice or snow produced during expansion. A full description of the machine may be found in a paper on "Air-Refrigerating Machinery" by Mr Coleman (*Proc. Inst. C.E.* vol. lxviii. 1882). At the present time the Bell-Coleman machine has practically ceased to exist. In such compressed-air machines as are now made there is no injection of water during compression, and the compressed air is cooled in a surface cooler, not by actual mixture with a shower of cold water. Further, though the interchanger is still used by some makers, it has been found by experience that, with properly constructed valves and passages in the expansion cylinder, there is no trouble from the formation of snow, when, as is the general practice, the same air is used over and over again, the compressor taking its supply from the insulated room or compartment. So far as the air discharged from the expansion cylinder is concerned, its humidity is precisely the same so long as its temperature and pressure are the same, inasmuch as when discharged from the expansion cylinder it is always in a saturated condition for that temperature and pressure. The manufacture of compressed-air machines has practically been confined to Great Britain.

In an actual machine the air is compressed to about 65 ℔ absolute, and its temperature is then about 300° Fahr. With cooling water at 60° and without an interchanger it will enter the expansion cylinder at about 70°, and after expansion will be cooled to about 70° below zero. The power given off in expansion is utilized for driving the compressor, the balance over and above that restored in expansion being applied either by a steam engine coupled to the machine or by some other source of power. With such a machine the ideal coefficient of performance is about 1, but the actual coefficient will be about $\frac{6}{10}$, after allowing for the losses incidental to working. Moisture, from which atmospheric air is never free, exercises an important effect in the working of

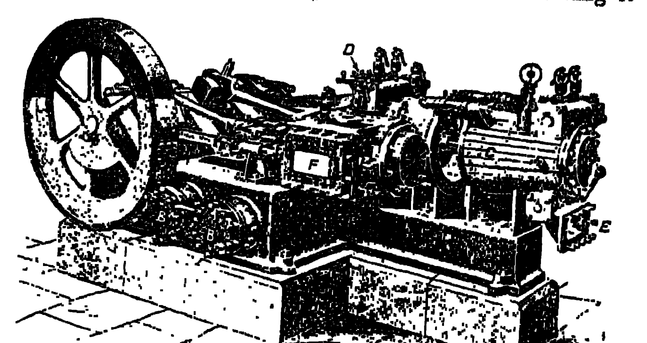

Fig. 2.—Compressed-Air Refrigerating Machine.

compressed-air machines. Even when the same air is used over and over again, moisture is abstracted from the cold room and its

contents, and the bulk of this must be got rid of in the machines, either in the form of water or of ice. A steam-driven compressed-air machine in a simple form is shown in Fig. 2. It consists of a compressor A, air coolers BB, an expansion cylinder C, and a steam engine F. Air, drawn into the compressor at D, is compressed to about 50 ℔ per square inch above the atmosphere, and then passed through the coolers BB, which are constructed like the surface condenser of a steam engine, the cooling water being pumped through the tubes and the air being on the outside. In the coolers it loses a portion of its moisture, which is condensed and runs off as water, and it then passes into the expansion cylinder C, where it is cut off at about one-third of the stroke and expanded behind a piston, thus giving back a portion of the power expended in compression. The thermal equivalent of the power given off on the piston, less an allowance for losses, is taken from the air, and the cold expanded air is discharged at E, to be utilized in the desired manner. The difference between the power expended in compression and that restored in expansion, plus the friction of the machine, is supplied by means of the steam engine F coupled to the crank-shaft. In the figure the expansion cylinder is placed tandem to the compressor, the two pistons being on the same rod. For marine purposes two complete machines are mounted on one bed-plate, the machines either being worked together, or in case of accident to one, separately. They are also made without a steam engine, the power being applied by means of a belt.

Liquid Machines.—Machines of the second class may conveniently be divided into three types:—(*a*) Those in which there is no recovery of the refrigerating agent, water being the agent employed; they will be dealt with as "Vacuum machines." (*b*) Those in which the agent is recovered by means of mechanical compression; they are termed "Compression machines." (*c*) Those in which the agent is recovered by means of absorption by a liquid; they are known as "Absorption machines."

Vacuum machines.

In the first class, since the refrigerating liquid is itself rejected, the only agent cheap enough to be employed is water. The boiling point of water varies with pressure; thus at one atmosphere or 14·7 ℔ per square inch it is 212° Fahr., whereas at a pressure of ·085 ℔ per square inch it is 32°, and at lower pressures there is a still farther fall in temperature. This property is made use of in vacuum machines. Water at ordinary temperature, say 60°, is placed in an air-tight glass or insulated vessel, and when the pressure is reduced by means of a vacuum pump it begins to boil, the heat necessary for evaporation being taken from the water itself. The pressure being still farther reduced, the temperature is gradually lowered until the freezing point is reached and ice formed when about one-sixth of the original volume has been evaporated.

The earliest machine of this kind appears to have been made in 1755 by Dr Cullen, who produced the vacuum by means of a pump alone. In 1810 Leslie combined with the air pump a vessel containing strong sulphuric acid for absorbing the vapour from the air, and is said to have succeeded in producing 1 to 1½ ℔ of ice in a single operation. Carré later adopted the same principle. In 1878 Windhausen patented a vacuum machine for producing ice in large quantities, and in 1881 one of these machines, said to be capable of making about 12 tons of ice per day, was put to work in London. The installation was fully described by Carl Pieper (*Trans. Soc. of Engineers*, 1882, p. 145) and by Dr John Hopkinson (*Journal of Soc. of Arts*, 1882, vol. xxxi. p. 20). The process, however, not being successful from a commercial point of view, was abandoned. At the present time vacuum machines are only employed for domestic purposes. The hand apparatus invented by Mr Fleuss consists of a vacuum pump capable of reducing the air pressure to a fraction of a millimetre, the suction pipe of which is connected first with a vessel containing sulphuric acid, and second with the vessel containing the water to be frozen. Both these vessels are mounted on a rocking base, so that the acid can be thoroughly agitated while the machine is being worked. As soon as the pump has sufficiently exhausted the air from the vessel containing the water, vapour is rapidly given off and is absorbed by the acid until sufficient heat has been abstracted to bring about the desired reduction in temperature, the acid becoming heated by the absorption of water vapour, while the water freezes. The small Fleuss machine will produce about 1¼ ℔ of ice in one operation of 20 minutes. Iced water in a carafe for drinking purposes can be produced in about three minutes. The acid vessel holds 9 ℔ of acid, and nearly 3 ℔ of ice can be made for each 1 ℔ of acid before the acid has become too weak to do further duty. Another machine, which can be easily worked by a boy, will produce 20 to 30 ℔ of ice in one hour, and is perhaps the largest size practicable with this method of freezing. The temperature attainable depends on the strength and condition of the sulphuric acid; ordinarily it can be reduced to zero Fahr., and temperatures 20° lower have frequently been obtained.

Compression machines.

Though prior to 1834 several suggestions had been made with regard to the production of ice and the cooling of liquids by the evaporation of a more volatile liquid than water, the first machine actually constructed and put to work was made by John Hague in that year from the designs of Jacob Perkins (*Journal of Soc. of Arts*, 1882, vol. xxxi. p. 77). This machine, though never used commercially, is the parent of all modern compression machines. Perkins in his patent specification states that the volatile fluid is by preference ether. In 1856 and 1857 James Harrison of Geelong, Victoria, patented a machine embodying the same principle as that of Perkins, but worked out in a much more complete and practical manner. It is stated that these machines were first made in New South Wales in 1859, but the first Harrison machine adopted successfully for manufacturing purposes was applied in the year 1861 for cooling oil in order to extract the paraffin. In Harrison's machine the agent used was ether $(C_2H_5)_2O$. Improvements were made by Siebe and Company, of London, and a considerable number of ether machines both for ice-making and refrigerating purposes were supplied by that firm and others up to the year 1880. In 1870 the subject of refrigeration was investigated by Professor Carl Linde of Munich, who was the first to consider the question from a thermodynamic point of view. He dealt with the coefficient of performance as a common basis of comparison for all machines, and showed that the compression vapour machine more nearly reached the theoretic maximum than any other (*Bayerisches Industrie und Gewerbeblatt*, 1870 and 1871). Linde also examined the physical properties of various liquids, and after making trials with methylic ether in 1872, built his first ammonia compression machine in 1873. Since then the ammonia compression machine has been most widely adopted, though the carbonic acid machine, also compression, which was first made in 1880 from Linde's designs, has of late years been used to a considerable extent.

A diagram of a vapour compression machine is shown in Fig. 3. There are three principal parts, a refrigerator or evaporator, a compression pump, and a condenser. The refrigerator, which

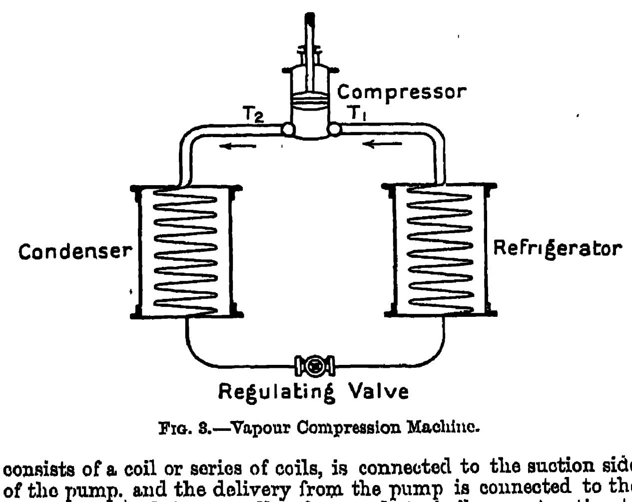

FIG. 3.—Vapour Compression Machine.

consists of a coil or series of coils, is connected to the suction side of the pump, and the delivery from the pump is connected to the condenser, which is generally of somewhat similar construction to

the refrigerator. The condenser and refrigerator are connected by a pipe in which is a valve named the regulator. Outside the refrigerator coils is the air, brine, or other substance to be cooled, and outside the condenser is the cooling medium, which, as previously stated, is generally water. The refrigerating liquid (ether, sulphur dioxide, anhydrous ammonia, or carbonic acid) passes from the bottom of the condenser through the regulating valve into the refrigerator in a continuous stream. The pressure in the refrigerator being reduced by the pump and maintained at such a degree as to give the required boiling point, which is of course always lower than the temperature outside the coils, heat passes from the substance outside, through the coil surfaces, and is taken up by the entering liquid, which is converted into vapour at the temperature T_1. The vapours thus generated are drawn into the pump, compressed, and discharged into the condenser at the temperature T_2, which is somewhat above that of the cooling water. Heat is transferred from the compressed vapour to the cooling water and the vapour is converted into a liquid, which collects at the bottom and returns by the regulating valve into the refrigerator. As heat is both taken in and discharged at constant temperature during the change in physical state of the agent, a vapour compression machine must approach the ideal much more nearly than a compressed-air machine, in which there is no change of state.

This will be seen by taking as an example a case in which the cold room is to be kept at 10° Fahr., the cooling water being at 60°. Under these conditions, the actual evaporating temperature T_1, in a well-constructed ammonia compression machine, after allowing for the differences necessary for the exchange of heat, would be about 5° below zero, and the discharge temperature T_2, would be about 70°. An ideal machine, working between 5° below zero and 70° above, has a coefficient of about 6·1, or more than 6 times that of an ideal compressed-air machine of usual construction to perform the same useful cooling work.

A vapour compression machine does not, however, work precisely in the reversed Carnot cycle, inasmuch as the fall in temperature between the condenser and the refrigerator is not produced, nor is it attempted to be produced, by the adiabatic expansion of the agent, but results from the evaporation of a portion of the liquid itself. In other words, the liquid refrigerating agent enters the refrigerator at the condenser temperature and introduces heat which has to be taken up by the evaporating liquid before any useful refrigerating effect can be performed. The extent of this loss is determined by the relation between the liquid heat and the latent heat of vaporization at the refrigerator temperature. If r represents the latent heat of the vapour, and q_2 and q_1 the amounts of heat contained in the liquid at the respective temperatures of T_2 and T_1, then the loss from the heat carried from the condenser into the refrigerator is shown by $\frac{q_2 - q_1}{r}$ and the useful refrigerating effect produced in the refrigerator is $r - (q_2 - q_1)$. Assuming, as in the previous example, that T_2 is 70° Fahr., and that T_1 is 5° below zero, the results for various refrigerating agents are as follows:—

TABLE II.

	Latent Heat. r	Liquid Heat. $q_2 - q_1$	Net Refrigeration. $r-(q_2-q_1)$	Proportion of Loss. $\frac{q_2-q_1}{r}$
Anhydrous ammonia	590·9	67·5	523·4	·110
Sulphurous acid .	173·1	27·3	145·8	·157
Carbonic acid . .	119·9	42·6	77·3	·351

The results show that the loss is least in the case of anhydrous ammonia and greatest in the case of carbonic acid. At higher condenser temperatures the results are even much more favourable to ammonia. As the critical temperature (88·4° Fahr.) of carbonic acid is approached the value of r becomes less and less and the refrigerating effect is much reduced. When the critical point is reached the value of r disappears altogether and a carbonic acid machine becomes dependent for its refrigerating effect on the reduction in temperature produced in the expansion of carbonic acid from the condenser pressure to that in the refrigerator. The abstraction of heat does not then take place at constant temperature. The vapour enters the refrigerator at a temperature much below that of the substance to be cooled, and whatever cooling effect is produced is brought about by the superheating of the vapour, the result being that above the critical point of carbonic acid the difference $T_2 - T_1$ is much increased and the efficiency of the machine is reduced. The critical temperature of anhydrous ammonia is about 266° Fahr., which is of course never approached in the ordinary working of refrigerating machines. Some of the principal physical properties of sulphurous acid, anhydrous ammonia, and carbonic acid are given in Tables III., IV., and V.

The action of a vapour compression machine is shown in Fig. 4. Liquid at the condenser temperature being introduced into the refrigerator through the regulating valve, a small portion evaporates and reduces the remaining liquid to the temperature T_1. This is shown by the curve AB, and is the useless work represented by the expression $\frac{q_2 - q_1}{r}$. Evaporation then continues at the constant temperature T_1 abstracting heat from the substance outside the refrigerator as shown by the line BC. The vapour

is then compressed along the line CD to the temperature T_2, when, by the action of the cooling water in the condenser, heat is abstracted at constant temperature and the vapour condensed along the line DA. Fig. 5 shows a complete ammonia compression machine applied to the cooling of a liquid such as water or brine. B is the refrigerator, consisting of a series of iron or steel coils placed inside a tank containing the liquid to be cooled, the liquid ammonia being admitted to the coils through a regulating valve. The compressor D draws off the vapour through the pipe C and compresses into the condenser F, the compressed vapour first passing through vessel E to separate any oil that may be held in suspension by the ammonia. The condenser is constructed on the same lines as the refrigerator, the cooling water being contained in the tank. A pipe takes the liquid from the bottom of the condenser coil to the regulating valve. A steam engine placed alongside the compressor supplies the necessary driving power, but the compressor may be driven by a belt or in any other convenient manner. The condenser is often made up of a series of coils without a tank, the cooling water falling over the coils into a collecting tray below; and this form is perhaps the most convenient for ordinary use, as it affords great facilities for inspection and painting. A compression machine using carbonic acid may be constructed on precisely the same lines as an ammonia machine, due allowance being made for the increased working pressures. In

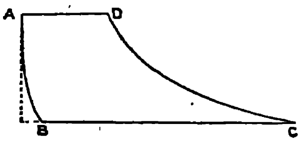

Fig. 4.—Action of Vapour Compression Machine.

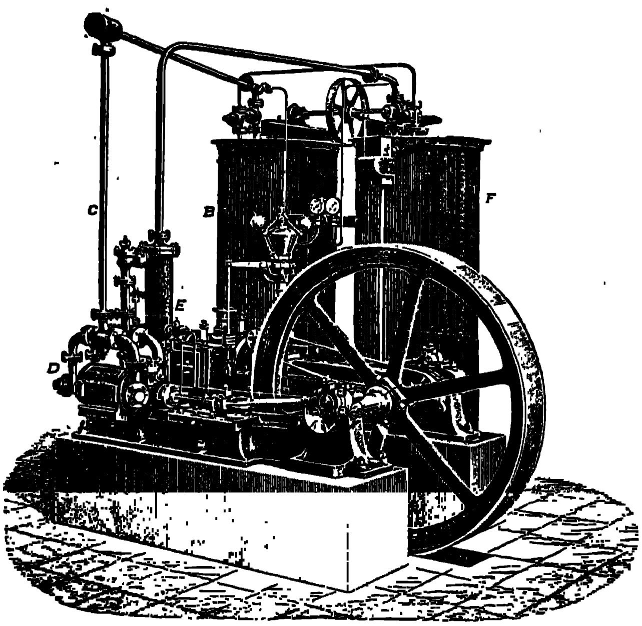

Fig. 5.—Ammonia Compression Machine.

the case of ammonia, copper and copper alloys must be avoided, though for carbonic acid they are not objectionable.

The compression of ammonia is sometimes carried out on what is known as the Linde or "wet" system, and sometimes on the "dry" system. When wet compression is used the regulating valve is opened to such an extent that a little more liquid is passed than can be evaporated in the refrigerator. This liquid enters the compressor with the vapour, and is evaporated there, the heat taken up preventing the rise in temperature during compression which would otherwise take place. The compressed vapour is discharged at a temperature but little above that of the cooling water. With dry compression, vapour alone is drawn into the compressor, and the temperature rises to as much as 180 or 200 degrees. Besides being more economical in working, wet compression possesses practical advantages in keeping the working parts of the compressor cool, and it also greatly facilitates the regulation of the liquid, to ensure the full duty of the machine being continuously performed. Some makers use a compression intermediate between the two systems. Very exact comparative trials have been made by Prof. Schroeter and others with compression machines using sulphur dioxide and ammonia. The results are published in *Vergleichende Versuche an Kältemaschinen*, by M. Schroeter, Munich, 1890, and in Nos. 32 and 51 of *Bayerisches Industrie und Gewerbeblatt*, 1892. Some of the results obtained by Prof. Schroeter in 1893 with an ordinary brine cooling machine on the Linde ammonia system are given in the following table.

The principle of the absorption process is chemical or physical rather than mechanical; it depends on the fact that many vapours of low boiling-point are readily absorbed in water, and can be separated again by the application of heat. In its simplest form an absorption machine consists of two iron vessels connected together by a bent pipe. One of these contains a mixture of ammonia and water, which on the application of heat gives off a mixed vapour containing a large proportion of ammonia, a liquid containing but little ammonia being left behind. In the second vessel, which is placed in cold water, the vapour rich in ammonia is condensed under pressure. To produce refrigeration the operation is reversed. On allowing the weak liquor to cool to normal temperature, it becomes greedy of ammonia (at 60° Fahr. at atmospheric pressure water will absorb about 760 times its own volume of ammonia vapour), and this produces an evaporation from the liquid in the vessel previously used as a condenser. This liquid, containing a large proportion of ammonia, gives off vapour at a low temperature and therefore becomes a refrigerator, abstracting heat from water or any surrounding body. When the ammonia is evaporated the operation as described must be again commenced. Such an apparatus is not much used now. Larger and more elaborate machines were made by Carré in France; but no very high degree of perfection was arrived at, owing to the impossibility of getting an anhydrous product of distillation. In 1867 Rees Reece, taking advantage of the fact that two vapours of different boiling-points, when mixed, can be separated by means of fractional condensation, brought out an absorption machine in which the distillate was very nearly anhydrous. By means of vessels termed the analyser and the rectifier, the bulk of the water was condensed at a comparatively high temperature and run back to the generator, while the ammonia passed into a condenser, and there assumed the liquid form under the pressure produced by the heat in the generator and the cooling action of water circulating outside the condenser tubes.

Absorption machines.

Fig. 6 is a diagram of an absorption apparatus. The ammonia vapour given off in the refrigerator is absorbed by a cold weak solution of ammonia and water in the absorber, and the strong liquor is pumped back into the generator through an interchanger through which also the weak hot liquor from the generator passes on its way to the absorber. In this way the strong liquor is heated before it enters the generator, and the weak liquor is cooled before it enters the absorber. The generator being heated by means of a steam coil, ammonia vapour is driven off at such a pressure as to cause its condensation in the condenser. From the condenser it passes into the refrigerator through a regulating valve in the usual manner. The process is continuous, and is identical with that of the compression machine, with the exception of the return from the temperature T_1 to the temperature T_2 which is brought about by the direct application of heat instead of by means of mechanical compression. With the same temperature range, however, the same amount of heat has to be acquired in both cases, though from the nature of the process the actual amount of heat demanded from the steam is much greater in the absorption system than in the compression. This is chiefly due to the fact that in the former the heat of vaporization acquired in the refrigerator is rejected in the absorber, so that the whole heat of vaporization has to be supplied

again by the steam in the generator. In the latter the vapour passes direct from the refrigerator to the pump, and power has to be expended merely in raising the temperature to a sufficient degree to enable condensation to occur at the temperature of the cooling water. On the other hand, a great advantage is gained in the absorption machine by using the direct heat of the steam, without first converting it into mechanical work, for in this way its

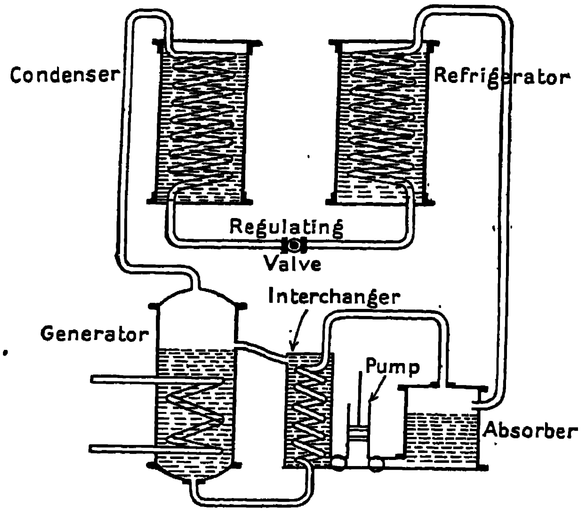

Fig. 6.—Absorption Apparatus.

latent heat of vaporization can be utilized by condensing the steam in the coils and letting it escape in the form of water. Each pound of steam can thus be made to give up some 950 units of heat; while in a steam engine only about 160 units are utilized in the steam cylinder per pound of steam, and in addition allowance has to be made for mechanical inefficiency. In the absorption machine the cooling water has to take up about twice as much heat as in the compression system, owing to the ammonia being

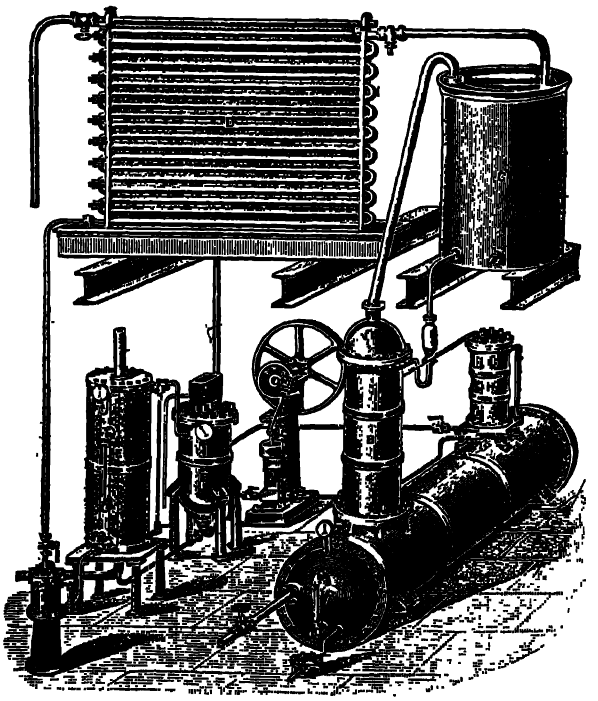

Fig. 7.—Modern Absorption Apparatus.

twice liquefied—namely, once in the absorber and once in the condenser. It is usual to pass the cooling water first through the condenser and then through the absorber.

The absorption machine is not so economical as the compression, but an actual comparison between the two systems is difficult to make. Information on this head is given in papers read by Dr Linde and by Professor Ewing before the Society of Arts (*Journal of the Society of Arts*, vol. xlii. 1894, p. 822, and Society of Arts 1897 Howard Lectures, January, February, and March 1897). The heat to be expended in the generator must at least equal the heat of absorption, plus the latent heat rejected in the condenser, plus the heat for superheating the vapours so as to give the pressure required for condensation. A modern absorption apparatus as applied to the cooling of liquids is shown in Fig. 7. A is the generator containing the coils, to which steam is supplied from an ordinary boiler not shown; B is the analyser; C, the rectifier; D, the condenser, which is shown of the open type; E, the refrigerator or cooler, in which the nearly anhydrous ammonia obtained in the condenser is allowed to evaporate; F, the absorber, through which weak liquor from the generator continually flows and absorbs the anhydrous vapour produced in the refrigerator; and G, the pump for forcing the strong liquor produced in the absorber back through the economizer, H, into the analyser, where, meeting with steam from the generator, the ammonia is again driven off, the process being thus carried on continuously. Sometimes an additional vessel is employed for heating the strong liquor by means of the exhaust steam from the engine driving the ammonia pump. Absorption machines are also made without a pump for returning the strong liquor to the generator. In these cases they work intermittently. In some machines the same vessel is used alternately as a generator and absorber, while in others, in order to minimize the loss of time, two vessels are provided which can be used alternately as generators and absorbers.

Applications.—Apart from the economical working of the machine itself, whatever system may be adopted, it is of importance that cold once produced should not be wasted, and it is therefore necessary to use some form of insulation to protect the vessels in which liquids are being cooled, or the rooms or ships' holds in which the freezing or storage processes are being carried on. Such insulation generally consists of materials such as charcoal, silicate cotton, granulated cork, small pumice, hair-felt, sawdust, &c., held between layers of wood or brick, and forming a more or less heat-tight box. There is no recognized standard of insulation. For a cold store to be erected inside a brick or stone building, and to be maintained at an internal temperature of from 18° to 20° Fahr., a usual plan is shown in Fig. 8. The same insulation is used for the floors and ceilings, except that the

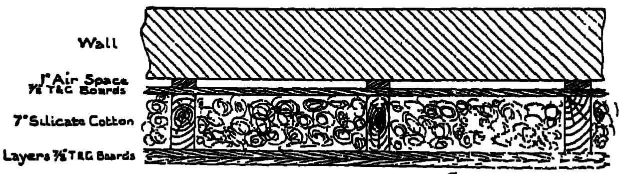

Fig. 8.—Insulation of a Cold Store.

wearing surface of the floor is generally made thicker than the inside lining of the sides. Should the walls or floor be damp, waterpoof paper is added. Granulated cork has practically the same insulating properties as silicate cotton, and the same thicknesses may be used. About 10 inches of flake charcoal and vegetable silica, or 11 of small pumice, are required to give the same protection as 7 inches of silicate cotton. In Germany cork bricks are largely used; these are made of granulated cork and some binding material, and they measure about 10 inches × 4⅞ × 2⅝ inches thick. For temperatures of about 35° Fahr. two courses of these bricks are laid against the wall of the building, and finished off on the inside with cement. For 20° three courses are used. The floors are similarly covered, and the bricks are protected by concrete or in some other manner according to the nature of the traffic on them. For lager-beer cellars and fermenting rooms, for bacon-curing cellars, and for similar purposes, brick walls with single or double air spaces are used, and sometimes a space filled with silicate cotton. In Australia and New Zealand pumice, which is found in enormous quantities in the latter country, takes the place of charcoal and silicate cotton. In Canada air spaces are largely used either alone or in combination

with silicate cotton or planer shavings. The air spaces, two or three in number, are formed between two layers of tongued and grooved wood, and the total thickness of the insulation is about the same as when silicate cotton alone is used. On board ship up to the present time charcoal has been almost entirely employed, but lately several vessels have been insulated with silicate cotton. The charcoal is either placed directly up to the skin of the vessel, and kept in place by a double lining of wood inside, in which case a thickness of about 10 inches is used, or it is placed between two layers of wood. With an air space, about 6 inches of flake charcoal is employed for the insulation of ships' holds, but for deck-houses and other parts exposed to the sun the thickness must be greater. A layer of sheet zinc or tin has frequently to be used as protection from rats. Given a certain allowable heat transmission, the principal points to be considered in connexion with insulation are, first cost, durability, weight, and space occupied, the two last named being specially important factors on board ship. No exact rules can be laid down, as the conditions vary so greatly; and though experiments have been made to determine the actual heat conduction of various materials per unit of surface, thickness, and temperature difference, the experience of actual practice is at present the only accepted guide.

Compressed-air machines discharge the cold air direct into the insulated room or hold, a snow box being generally provided close to the outlet of the expansion cylinder to catch the snow and congealed oil. The air is distributed by means of wood air trunks with openings controlled by slides, and similar trunks are provided in connexion with the suction of the compressor to conduct the air back to the machine. With machines of the compression and absorption system, the rooms are either cooled by means of cold pipes or surfaces placed in them, or by a circulation of air cooled in an apparatus separated from the rooms. The cold pipes may be direct-expansion pipes in which the liquid ammonia evaporates, or they may be pipes or walls through which circulates an uncongealable brine previously cooled to the desired temperature. The pipes are placed on the ceilings or walls, according to circumstances, but they must be arranged so as to induce a circulation of air throughout the compartment and ensure every part being cooled. With what is termed the air circulation system the air is generally circulated by means of a fan, being drawn from the rooms through ducts, passed over a cooler, and returned again to the rooms by other ducts. In some coolers the cooling surfaces consist of direct-expansion pipes placed in clusters of convenient form; in others brine pipes are used; in others there is a shower of cold brine, and in some cases combinations of cold pipes and brine showers. Whether pipes in the rooms or air circulation give the best results is to some extent a matter of opinion, but at the present time the tendency is decidedly in favour of air circulation, at any rate for general cold storage purposes. Whichever system be adopted, it is important for economical reasons that ample cooling surface be allowed, and that all surfaces be kept clean and active, to make the difference between the temperature of the evaporating liquid and the rooms as small as possible. Small surfaces reduce first cost, but involve higher working expenses by increasing the value of $\frac{T_1}{T_2 - T_1}$, and thus demanding more energy, and consequently more fuel to effect the given result than if larger surfaces were employed.

Liquids are generally cooled in a refrigerator similar to that shown in Fig. 5, entering the tank at the top and passing off at the bottom.

The general arrangement of an ice factory for producing can ice is shown in Fig. 9. The water to be frozen is contained in galvanized or terned steel moulds suspended in a tank filled to the proper level with brine maintained at the desired temperature. The moulds are frequently arranged in frames, so that by means of an overhead crane one complete row is lifted at a time. When the water is frozen the moulds are dipped in a tank containing warm water, and on being tipped the blocks of ice fall out. Ordinary water contains air, and ice made from it is generally opaque, due to the inclusion of numerous small air-bubbles. To produce clear ice the water must be agitated during the freezing process, or previously boiled to get rid of the air. Distilled water is frequently used, as well as the water produced by the condensation of the steam from the engine, which of course must be thoroughly purified and filtered. It should be noted, however, that with an ice-making plant of moderate size and a steam engine of good construction the weight of steam used will not nearly equal the weight of ice produced, so that the difference must be made up either by distillation, which is a costly process, or by ordinary water. Can ice is usually made in blocks weighing 56, 112, or 224 lb, and from 4 to 8 inches thick. For cell ice ordinary water is used, agitated during freezing. The cells are flat and constructed of galvanized iron, so as to form a hollow space of about 2 inches in width, through which cold brine is circulated by a pump. They are placed vertically in a tank, the distance between them being from 8 to 14 inches, according to the thickness of the ice to be produced. The tank is filled with water, which is kept in agitation by means of a reciprocating paddle or piston; in this way the air escapes, and with proper care a block of great transparency is produced. To thaw it off warm brine is circulated through the cells. A usual size for cell ice is 4 feet by 3 feet by

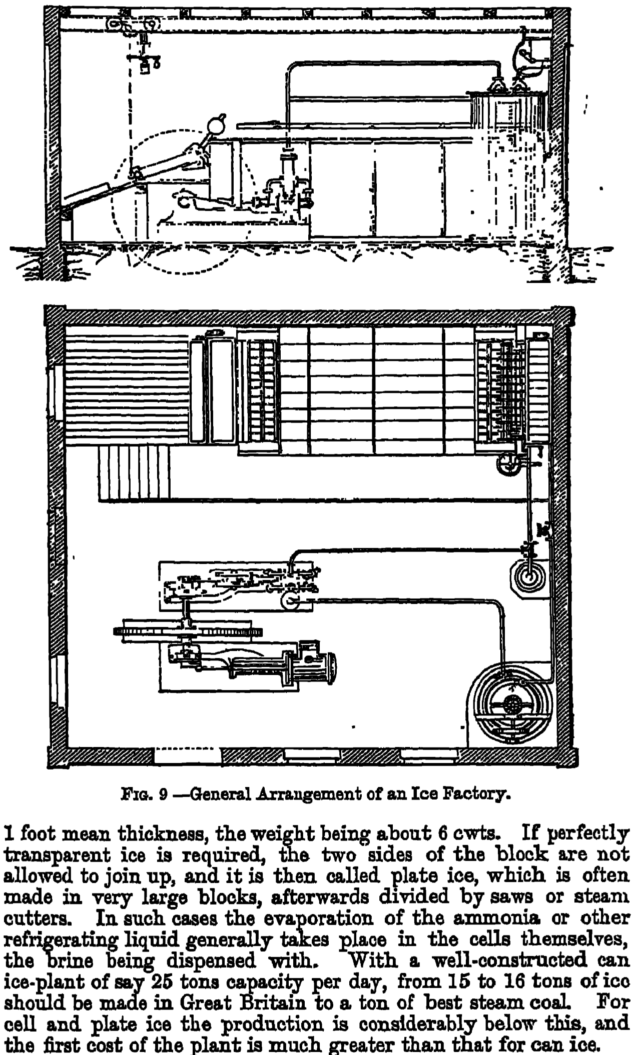

FIG. 9 —General Arrangement of an Ice Factory.

1 foot mean thickness, the weight being about 6 cwts. If perfectly transparent ice is required, the two sides of the block are not allowed to join up, and it is then called plate ice, which is often made in very large blocks, afterwards divided by saws or steam cutters. In such cases the evaporation of the ammonia or other refrigerating liquid generally takes place in the cells themselves, the brine being dispensed with. With a well-constructed can ice-plant of say 25 tons capacity per day, from 15 to 16 tons of ice should be made in Great Britain to a ton of best steam coal. For cell and plate ice the production is considerably below this, and the first cost of the plant is much greater than that for can ice.

Fig. 10 shows an arrangement of cold storage on land, refrigerated on the air circulation system. The insulated rooms, on two floors, are approached by corridors, so as to exclude external air, which if allowed to enter would deposit moisture upon the goods. The air cooler is placed at the end, and the air is distributed by means of wood ducts furnished with slides for regulating the temperature of the rooms which are insulated according to the method shown in Fig. 9. In some cases, instead of the entrance being at the sides or ends, it is at the top, all goods being raised to the top floor in lifts and lowered by lifts into the rooms. With good machinery the cost of raising is not great, and is probably equalled by the saving in refrigeration, since the rooms hold the heavy cold air as a glass holds water.

Large passenger vessels and yachts are now generally fitted with refrigerating machinery for preserving provisions, cooling water and wine, and making ice. Usually two insulated compartments are provided, one for frozen meats at about 20° Fahr., and one for vegetables, &c., at about 40°. They have a capacity of from 1500 to 3000 cubic feet, according to the number of passengers carried, and they are generally cooled by means of brine pipes, though direct expansion and air circulation are sometimes adopted. A passenger

vessel requires from 2 to 4 cwts. of ice per day. On battle-ships and cruisers the British Admiralty use small compressed-air machines for ice-making, the present standard being a production of 80 lb of ice per day, without provision rooms. A modern frozen meat carrying vessel will accommodate as much as 120,000 carcases, partly sheep and partly lambs, requiring a hold capacity of about 300,000 cubic feet. In some vessels both fore and aft holds and 'tween decks are insulated. Lloyd's Committee now issue certificates for refrigerating installations, if constructed according to their rules, and most modern cargo-carrying vessels have their refrigerating machinery classed at Lloyd's. In the meat trade between the River Plate, the United States, Canada, and

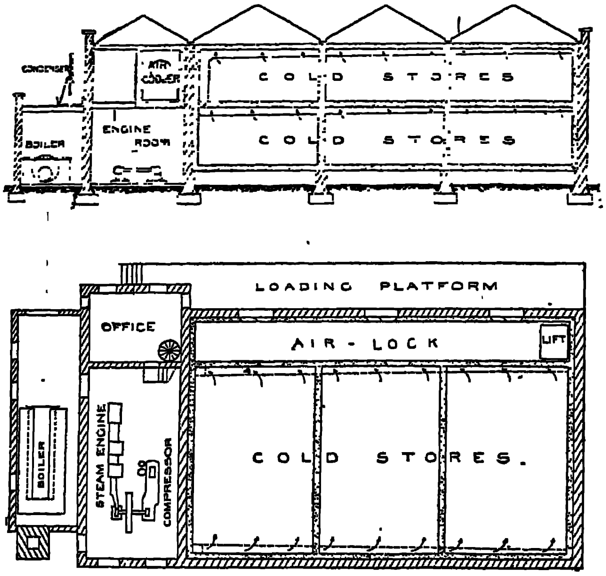

FIG. 10.—Cold Stores.

Great Britain, ammonia or carbonic acid machines are now exclusively used, but for the Australian and New Zealand frozen meat trade compressed-air machines are still to some extent adopted. The holds of meat-carrying vessels are refrigerated either by cold air circulation or by brine pipes.

Though the adoption of refrigerating and ice-making machinery for industrial purposes practically dates from the year 1880, the manufacture of these machines has already assumed very great proportions; indeed, in no branch of mechanical engineering, with the exception of electrical machinery, has there been so remarkable a development in recent years. The sphere of application is extending year by year. The cooling of residential and public buildings in hot countries is yet untouched, the manufacture of ice and the preservation of perishable foods (apart from the frozen meat trade) have in many countries hardly received serious consideration, while in breweries, dairies, margarine works, and many other industries there is a large and increasing field for refrigerating and ice-making machinery.

Regeneration of Lost Parts.—A loss and renewal of living material, either continual or periodical, is a familiar occurrence in the tissues of higher animals. The surface of the human skin, the inner lining of the mouth and respiratory organs, the blood corpuscles, the ends of the nails, and many other portions of tissues are continuously being destroyed and replaced. The hair of many mammals, the feathers of birds, the epidermis of reptiles, and the horns of stags are shed and replaced periodically. In these normal cases the regeneration depends on the existence of special formative layers or groups of cells, and must be regarded in each case as a special adaptation, with individual limitations and peculiarities, rather than as a mere exhibition of the fundamental power of growth and reproduction displayed by living substance. Many tissues, even in the highest animals, are capable of replacing an abnormal loss of substance. Thus in mammals, portions of muscular tissue, of epithelium, of bone, and of nerve, after accidental destruction or removal, may be renewed. The characteristic feature of such cases appears to be, in the higher animals at any rate, that lost cells are replaced only from cells of the same morphological order—epiblastic cells from the epiblast, mesoblastic from the mesoblast, and so forth. The process is in direct relation to the general power of growth and reproduction possessed by protoplasm, and is regarded by pathologists as the consequence of "removal of resistances to growth." It is much less common in the tissues of higher plants, in which the adult cells have usually lost the power of reproduction, and in which the regeneration of lost parts is replaced by a very extended capacity for budding. Still, more complicated reproductions of lost parts occur in many cases, and are more difficult to understand.

Fraisse has shown that in Amphibia the entire epidermis, together with the slime-glands and the integumentary sense-organs, is regenerated by the epidermic cells in the vicinity of the defect. The whole limb of a Salamander or a Triton will grow again and again after amputation. Similar renewal is either rarer or more difficult in the case of Siren and Proteus. In frogs regeneration of amputated limbs does not take place. Chelonians, crocodiles, and snakes are unable to regenerate lost parts to any extent, while lizards and geckoes possess the capacity in a high degree. The capacity is absent almost completely in birds and mammals. In cœlenterates, worms, and tunicates the power is exhibited in a very varying extent. In Hydra, Nais, and Lumbriculus, after transverse section, each part may complete the whole animal. In most worms the greater, and in particular the anterior part, will grow a new posterior part, but the separated posterior portion dies. In Hydra, sagittal and horizontal amputations result in the completion of the separated parts. In worms such operations result in death, which no doubt may be a mere consequence of the more severe wound. Extremely interesting instances of regeneration are what are called "Heteromorphoses," where the removed part is replaced by a dissimilar structure. The tail of a lizard, grown after amputation, differs in structure from the normal tail: the spinal cord is replaced by an epithelial tube which gives off no nerves; the vertebræ are replaced by an unsegmented cartilaginous tube. Loeb produced many heteromorphoses on lower animals. He lopped off the polyp head and the pedal disc of a Tubularia, and supported the lopped stem in an inverted position in the sand; the original pedal end, now superior, gave rise to a new polyp head, while the neck-end, on regeneration, formed a pedal disc. In Cerianthus, a sea-anemone, and in Cione, an ascidian, regeneration after his operations resulted in the formation of new mouth-openings in abnormal places, surrounded by elaborate structures characteristic of normal mouths.

It appears that, in the same fashion as more simply organized animals display a capacity for reproduction of lost parts greater than that of higher animals, so embryos and embryonic structures generally have a higher power of renewal than that displayed by the corresponding adult organs or organisms. Moreover, experimental work on the young stages of organisms has revealed a very striking series of phenomena, similar to the heteromorphoses in adult tissues, but more extended in range. Driesch, O. Hertwig, and others, by separating the segmentation spheres, by destroying some of them, by compressing young embryos by glass plates, and by many other means, have caused cells to develop so as to give rise to structures which in normal development they would not have formed.

It is clear that there are at least three kinds of factors involved in regeneration, and that theoretical explanations must take into account, more definitely than has yet been done, these essential differences. There are: (1) Regenerations due to the presence of undifferentiated, or little differentiated, cells, which have retained the normal capacity

of multiplication when conditions are favourable. (2) Regenerations due to the presence of special complicated rudiments, the stimulus to the development of which is the removal of the fully-formed structure. (3) Regeneration involving the general capacity of protoplasm to respond to changes in the surroundings by changes of growth. The most general view is to regard regenerations as special adaptations; and Weismann, following in this matter Arnold Lang, has developed the idea at considerable length, and has found a place for regenerations in his system of the germ-plasm (see HEREDITY) by the conception of the existence of "accessory determinants." Hertwig, on the other hand, attaches great importance to the facts of regeneration as evidence for his view that every cell of a body contains a similar essential plasm. Our knowledge of the facts is not yet sufficiently systematic to allow of useful criticism of these opposing views. (P. C. M.)

Reggio di Calabria, a town and archiepiscopal see of Calabria, Italy, capital of the province of Reggio, stands at the south-west extremity of Italy, on the Straits of Messina, 7 miles south-south-east of Messina in Sicily, and 248 miles from Naples by rail. In 1894 the town suffered from an earthquake, though less severely than in 1783. It possesses an archæological museum, a school of the industrial arts, and statues to Garibaldi and Italy. Ancient Græco-Roman baths have been excavated near the shore. The port has been enlarged and improved since 1896, and a new town hall was built in 1897. The manufacture of bergamot and other essential oils, of olive oil, and of silk, with some printing, are the principal industries. In 1897 its port was cleared by 624 vessels of 433,349 tons. Population (1881), 35,437; (1901), 44,417.

Reggio nell' Emilia, a city and episcopal see of Emilia, Italy, capital of the province of the same name, 38 miles north-west of Bologna by rail. Its public buildings include the church of the Madonna della Ghiara (1597), a Renaissance structure with fine domes, built in the form of a Greek cross; an archæological museum; and an industrial institute, a school of design, and a specialized school of agriculture (1879). Its industries embrace the making of cheese, objects in cement, matches, and brushes, the production of silkworms, and printing. Population (1881), 18,634; (1901), 59,176.

Regina, a town and port of entry of Assiniboia, Canada, and the capital of the North-West Territories, is situated 357 miles (by rail) west of Winnipeg, on Wascana creek and the Canadian Pacific Railway, in 104° 36′ W. and 50° 27′ N., at an altitude of 1885 feet above the sea. It contains the Government buildings and headquarters of the Indian Department and of the North-West Mounted Police. Population (1901), 2645.

Registration of Voters.—Registration was not altogether unknown in Great Britain in connexion with the parliamentary franchise before the Reform Acts of 1832. Thus in the Scottish counties the right to vote depended on the voter's name being upon the roll of freeholders established by an Act of Charles II.; a similar register existed in Ireland of freeholders whose freeholds were under £20 annual value; and in the Universities of Oxford and Cambridge the rolls of members of Convocation and of the Senate were, as they still are, the registers of parliamentary voters. But except in such cases as the above, the right of a voter had to be determined by the returning officer upon the evidence produced before him when the vote was tendered at a poll. This necessarily took time, and the result was that a contested election in a large constituency might last for weeks. The celebrated Westminster election of 1784, in which the poll began on the 1st of April and ended on the 17th of May, may be mentioned as an illustration. Moreover, the decision of the returning officer was not conclusive; the title of every one who claimed to vote was liable to be reconsidered on an election petition, or, in the case of a rejected vote, in an action for damages by the voter against the returning officer. The inconvenience of such a state of things would have been greatly aggravated had the old practice continued after the enlargement of the franchise in 1832. The establishment of a general system of registration was therefore a necessary and important part of the reform then effected. It has enabled an election in the most populous constituency to be completed in a single day. It has also been instrumental in the extinction of the "occasional voter," who formerly gave so much trouble to returning officers and election committees—the person, namely, who acquired a qualifying tenement with the view of using it for a particular election and then disposing of it. The period of qualification now required in all cases, being fixed with reference to the formation of the register, is necessarily so long anterior to any election which it could affect, that the purpose or intention of the voter in acquiring the qualifying tenement has ceased to be material, and is not investigated.

England.—The reform of parliamentary representation in 1832 was followed in 1835 by that of the constitution of municipal corporations, which included the creation of a uniform qualification (now known as the old burgess qualification) for the municipal franchise. In 1888 the municipal franchise was enlarged, and was at the same time extended to the whole country for the formation of constituencies to elect county councils; and in 1894 parochial electors were called into existence for the election of parish councils and for other purposes. Inasmuch as provision was made for the registering of persons entitled to votes for the above purposes, there are now three registers of voters, namely, the parliamentary register, the local government register (*i.e.*, in boroughs under the Municipal Corporation Acts, the burgess rolls, and elsewhere the county registers), and the register of parochial electors. Under the Municipal Corporations Act, 1835, the registration of burgesses, though on similar lines to that of parliamentary voters, was entirely separate from it. Since, however, the qualification for the municipal franchise covered to a great extent the same ground as that for the parliamentary franchise in boroughs which sent members to Parliament, a considerable number of voters in such boroughs were entitled in respect of the same tenement to be upon both parliamentary register and burgess roll. The waste of labour involved in settling their rights twice over was put an end to in 1878, when the system of parliamentary registration was extended to the boroughs in question for municipal purposes, and the lists were directed to be made out in such a shape that the portion common to the two registers could be detached and combined with the portion peculiar to each, so as to form the parliamentary register and the burgess roll respectively. This system of registration was extended to the non-parliamentary boroughs and to the whole country in 1888, the separate municipal registration being completely abolished.

Procedure.

The procedure of parliamentary registration is to be found in its main lines in the Parliamentary Registration Act, 1843, which superseded that provided by the Reform Act of 1832, and has itself been considerably amended by later legislation. The Acts applying and adapting the system to local government and parochial registration are the Parliamentary and Municipal Registration Act, 1878, the County Electors Act, 1888, and the Local Government Act, 1894. Registration is carried out by local machinery, the common-law parish being taken

as the registration unit; and the work of preparing and publishing the lists, which when revised are to form the register, is committed to the overseers. The selection of these officers was no doubt due to their position as the rating authority, and to their consequent opportunities for knowing the ownership and occupation of tenements within their parish. They do not always perform the duties themselves, other persons being empowered to act for them in many parishes by general or local Acts of Parliament; but in all or almost all cases they are entitled to act personally if they think fit, they sign the lists, and the proceedings are conducted in their name.

In order to render intelligible the following summary of the procedure, it will be necessary to divide the voters to be registered into classes based on the nature of their qualification, since the practice differs in regard to each class. The classes are as follows:—(1) Owners, including the old forty-shilling freeholders, and the copyholders, long leaseholders, and others entitled under the Reform Act of 1832 to vote at parliamentary elections for counties; (2) occupiers, including those entitled to (*a*) the £10 occupation qualification, (*b*) the household qualification, and (*c*) the old burgess qualification; (3) lodgers, subdivided into (*a*) old, *i.e.*, those on the previous register for the same lodgings, and (*b*) new; (4) those entitled to reserved rights, *i.e.*, in addition to those (if any still remain) who were entitled to votes before the Reform Act of 1832 in respect of qualifications abolished by that Act, (*a*) freehold and burgage tenants in Bristol, Exeter, Norwich, and Nottingham, and (*b*) liverymen of the City of London and freemen of certain old cities and boroughs, whose right to the parliamentary franchise was permanently retained by the same Act. In regard to these classes it may be said that the general scheme is that owners must make a claim in the first instance before they can get their names upon the register, but that, once entered on the register, the names will be retained from year to year until removed by the revising barrister; that the lists of occupiers and of freehold and burgage tenants are made out afresh every year by the overseers from their own information and inquiries, without any act being required on the part of the voters, who need only make claims in case their names are omitted; that lodgers must make claims every year; and that liverymen and freemen are in the same position as occupiers, except that the lists of liverymen are made out by the clerks of the several companies, and those of freemen by the town clerks, the overseers having nothing to do with these voters, whose qualifications are personal and not locally connected with any parish.

The overseers and other officers concerned are required to perform their duties in connexion with registration in accordance with the instructions and precepts, and to use the notices and forms prescribed by Order in Council from time to time. The Order at present in force is the Registration Order, 1895. It directs the clerk of every county council, on or within seven days before the 15th of April in every year, to send to the overseers of each parish in his county a precept with regard to the registration of ownership electors, and to every parish not within a parliamentary or municipal borough a precept with regard to the registration of occupation electors (which expression for this purpose includes lodgers as well as occupiers proper). The town clerk of every borough, municipal or parliamentary, is to send to the overseers of every parish in his borough a precept with regard to the registration of occupation electors. These precepts are set out in the Registration Order, and those issued by the town clerks differ according as the borough is parliamentary only, or municipal only, or both parliamentary and municipal; in the cases of Bristol, Exeter, Norwich, and Nottingham they contain directions as to freehold and burgage tenants. The duties of the overseers in regard to registration are set out in detail in the precepts. Along with the precepts are forwarded forms of the various lists and notices required to be used, and with the ownership precept a certain number of copies of that portion of the parliamentary register of the county at the time in force which contains the ownership voters for the parish, the register being so printed that the portion relating to each parish can be detached. It is the duty of the overseers to publish on the 20th of June, in manner hereinafter described, the portion of the register so received, together with a notice to owners not already registered to send in claims by the 20th of July. Meanwhile the overseers are making the inquiries necessary for the preparation of the occupier list. For this purpose they may require returns to be furnished by owners of houses let out in separate tenements, and by employers who have servants entitled to the service franchise. The registrars of births, deaths, and marriages are required to furnish the overseers with returns of deaths, and the assessed tax collectors with returns of defaulters; the relieving officers are to give information as to recipients of parochial relief. On or before the 31st of July the overseers are to make out and sign the lists of voters. These are the following: the list of ownership electors, consisting of the portion of the register previously published with a supplemental list of those who have sent in claims by the 20th of July; the occupier list; and the old lodger list, the last being formed from claims sent in by the 25th of July. The overseers do not select the names in the first and last of these lists; they take them as supplied in the register and claims. It is, however, their duty to write "dead" or "objected" in the margin against the names of persons whom they have reason to believe to be dead or not entitled to vote in respect of the qualification described. The ownership and old lodger lists will be divided into two parts, if the register contains names of owners entitled to a parochial vote only, or if claims by owners or old lodgers have been made limited to that franchise. The occupier list contains the names of persons whom the overseers believe to be qualified, and no others, and therefore will be free from marginal objections. Except in the administrative county of London, it is made out in three divisions—division 1 giving the names of occupiers of property qualifying for both parliamentary and local government votes, divisions 2 and 3 those of occupiers of property qualifying only for parliamentary and only for local government votes respectively. It happens so frequently that a tenement, if not of sufficient value to qualify for the £10 occupation franchise (parliamentary and local government), qualifies both for the household franchise (parliamentary) and for the old burgess franchise (local government), that division 1 would in most cases be the whole list, but for two circumstances. The service franchise is a special modification of the household franchise only; and the service occupants, being therefore restricted to the parliamentary vote, form the bulk of division 2; while peers and women, being excluded from the parliamentary vote, are consequently relegated to division 3. In the administrative county of London the local government register, being coextensive with the register of parochial electors, includes the whole of the parliamentary register. The occupier lists are consequently there made out in two divisions only, the names which would elsewhere appear in division 2 being placed in division 1. The lists of freehold and burgage tenants in Bristol, Exeter, Norwich, and Nottingham are to be made out and signed by the same date. The overseers have also to make out and sign a list of persons qualified as occupiers to be elected aldermen or councillors, but as non-residents

disqualified from being on the local government register. By the same date also the clerks of the livery companies are to make out, sign, and deliver to the secondary (who performs in the City of London the registration duties which elsewhere fall on the town clerk) the lists of liverymen entitled as such to the parliamentary vote; and the town clerks are to make out and sign the lists of freemen so entitled in towns where this franchise exists.

On the 1st of August all the above lists are to be published, the livery lists by the secondary, lists of freemen by the town clerks, and the rest by the overseers. In addition the overseers may have to publish a list of persons disqualified by having been found guilty of corrupt or illegal practices; this list they will receive, when it exists, from the clerk of the county council or town clerk with the precept. Publication of lists and notices by overseers is made by affixing copies on the doors of the church and other places of worship of the parish (or, if there be none, in some public or conspicuous situation in the parish), and also, with the exception to be mentioned, in the case of a parish wholly or partly within a municipal borough or urban district, in or near every public or municipal or parochial office and every post and telegraph office in the parish. The exception is that lists and notices relating to ownership electors need not be published at the offices mentioned when the parish is within a parliamentary borough. Publication by the secondary is made by affixing copies outside the Guildhall and Royal Exchange; publication by town clerks is made by affixing copies outside their town hall, or, where there is none, in some public or conspicuous place in their borough. From the 1st to the 20th of August inclusive is allowed for the sending in of claims and objections. Those whose names have been omitted from the occupier or reserved rights lists, or the non-resident list, or whose names, place of abode, or particulars of qualification have been incorrectly stated in such lists, may send in claims to have their names registered; lodgers who are not qualified as old lodgers, or who have omitted to claim as such, may claim as new lodgers; persons whose names are on the corrupt and illegal practices list may claim to have them omitted. Any person whose name is on the list of parliamentary, local government, or parochial electors for the same parliamentary county, administrative county, borough, or parish, may object to names on the same lists. Notices of claim and objection in the case of liverymen and freemen are to be sent to the secondary and town clerk, and in other cases to the overseers; and notices of objection must also in all cases be sent to the person objected to. All notices must be sent in by the 20th of August, and on or before the 25th of August the overseers, secondary, and town clerks are to make out, sign, and publish lists of the claimants and persons objected to. It remains to be added that any person on a list of voters (*i.e.*, on one of the lists published on the 1st of August) may make a declaration before a magistrate or commissioner for oaths correcting the entry relating to him. In the case of ownership electors the correction can only deal with the place of abode; in the case of other lists it extends to all particulars stated, and is useful inasmuch as it enables the revising barrister to make corrections as to the qualification which he could not make in the absence of a declaration. The declarations must be delivered to the clerk of the county council or town clerk on or before the 5th of September.

The next stage is the revision of the lists. For this purpose revising barristers are appointed yearly, for the Middlesex circuit (which includes the whole of the old county of Middlesex and the City of London) by the Lord Chief-Justice, for the other counties and boroughs by the senior judge going the summer assize on the circuits to which they respectively belong. The period within which revision courts can be held is from the 8th of September to the 12th of October, both days inclusive. The clerk of the county council attends the first court held for each parliamentary division of his county, and the town clerk the first court held for his city or borough; and they are respectively to produce all lists, notices, and declarations in their custody, and to answer any questions put to them by the revising barrister. The overseers also attend the courts held for their parish, to produce the rate books, original notices of claim and objection, &c., and to answer questions. The claimants, objectors, and persons objected to appear personally or by representative to support their several contentions. Any person qualified to be an objector may also appear to oppose any claims, upon giving notice to the barrister before such claims are reached. The powers of the revising barrister are as follow:—As regards persons whose names are on the lists of voters published on the 1st of August, he is to expunge the names, whether objected to or not, of those who are dead or subject to personal incapacity, such as infants and aliens, and for parliamentary purposes peers and women; but this class of persons has been held not to include those incapacitated by receipt of parochial relief, whose names therefore cannot be expunged unless objected to. If an entry is imperfect, the name must be removed, unless the particulars necessary for completing it are supplied to the barrister. All names marginally objected to by overseers must be expunged, unless the voters prove to the barrister that they ought to be retained. Objections made by other objectors must be supported by *primâ facie* proof, and if this is not rebutted the name is struck out. Claimants (including owners and old lodgers who have duly claimed, but whose names for whatever cause have been omitted from the lists of voters published on the 1st of August) must be ready to support their claims. The declaration attached to a lodger claim is indeed *primâ facie* proof of the facts stated in it, but other claimants require evidence to make out even a *primâ facie* case, and if they fail to produce it their claims will be disallowed. The barrister is required to correct errors in the lists of voters, and has a discretion to rectify mistakes in claims and objections upon evidence produced to him. But his power in this respect is limited, and in particular he may not correct the description of qualification in a list of voters (except upon the evidence of a declaration made as above mentioned), or in a claim, so as to make it a different qualification from that stated in the list or claim. Lastly, the barrister has to deal with duplicates. A voter is entitled to be on the register once, but not more than once, as a parliamentary voter for each parliamentary county or borough, as a burgess for each municipal borough, as a county elector for each electoral division, and as a parochial elector for each parish in which he holds a qualification. But inasmuch as the overseers of a parish cannot say with certainty what entries relating to any person will appear on the lists of other parishes, nor which of them or of any duplicates on their own lists will be retained on revision, it is their duty to place each name on the lists where it would be if there were no duplicate, leaving it to the revising barrister to deal with the duplicate entries by expunging or transferring them to a separate parochial list, or, in the case of occupiers, to division 2 or 3 of the occupier list, as required. The revising barrister has also, as regards freemen in a divided parliamentary borough, to allot the non-residents equally as nearly as may be among the parliamentary divisions, the residents being placed on the

Revising barristers.

list of the division where they reside. The decision of the revising barrister is final and conclusive on all questions of fact; but an appeal lies from him on questions of law at the instance of any person aggrieved by the removal of his name from a list of voters, by the rejection of his claim or objection, or by the allowance of a claim which he has opposed. Notice of the intention to appeal must be given to the barrister in writing on the day when his decision is given. The barrister may refuse to state a case for appeal; but if he does so without due cause he may be ordered by the High Court to state a case. The appeal is heard by a Divisional Court, from whose decision an appeal lies (by leave either of the Divisional Court or of the Court of Appeal) to the Court of Appeal, whose decision is final.

On the completion of the revision the barrister hands the county and borough lists (every page signed and every alteration initialled by him) to the clerk of the county council and the town clerk respectively, to be printed. It is to be observed that the ownership list is a county list, whether the parish be within a borough or not, and will in all cases be handed to the clerk of the county council. With the following exceptions the revised lists are to be made up and printed by the 20th of December, and come into force as the register for all purposes on the 1st of January. In the boroughs created by the London Government Act, 1899, the whole register is to be made up and printed by the 20th of October, and to come into force for the purpose of borough elections under the Act on the 1st of November. In boroughs subject to the Municipal Corporations Acts, divisions 1 and 3 of the occupiers' list are to be made up and printed by the 20th of October, and come into force for the purpose of municipal and county council elections on the 1st of November. Corrections ordered in consequence of a successful appeal from a revising barrister are to be made by the officers having the custody of the registers, but a pending appeal does not affect any right of voting. The register in its final form will consist of the lists published on the 1st of August as corrected, with the claims which have been allowed on revision incorporated with them. It is printed in such form that each list and each division of a list for every parish can be separated from the rest for the purpose of making up the parliamentary, local government, and parochial registers respectively. The alphabetical order is followed, except in London and some other large towns, where street order is adopted for all except the ownership lists and lists of liverymen and freemen. The parliamentary register for a parliamentary county will consist of the ownership lists for all parishes in the county, and of the lodger lists and divisions 1 and 2 of the occupier lists for parishes within the county and not within a parliamentary borough. The parliamentary register for a parliamentary borough will consist of the lodger lists, of the lists of freehold and burgage tenants (if any), and of divisions 1 and 2 of the occupier lists for all parishes within the borough, and also of the borough lists (if any) of liverymen or freemen. The local government register for an administrative county will consist of divisions 1 and 3 of the occupier lists for all parishes in the county, and the burgess roll for a municipal borough of divisions 1 and 3 of the occupier lists for all parishes in the borough. It will be seen, therefore, that, except in county boroughs, the burgess roll is also a part of the local government register of the administrative county within which the borough is situate. The register of parochial electors consists of the complete set of lists for each parish; but this does not include the lists of liverymen and freemen, which, as has been stated, are not parish lists.

No one whose name is not on the register can vote at an election. The fact that a man's name is on the register is now so far conclusive of his right that the returning officer is bound to receive his vote. Only two questions may be asked of him when he tenders his vote, namely, whether he is the person whose name is on the register, and whether he has voted before at the election. The Reform Act, 1832, allowed him to be asked at parliamentary elections whether he retained the qualification for which he had been registered; but the Registration Act, 1843, disallowed the question, and made the register conclusive as to the retention of the qualification. When, however, a petition is presented against an election, the register, although conclusive as to the retention of the qualification, does not prevent the court from inquiring into the existence of personal incapacities, arising in connexion with the election or otherwise, and striking off on scrutiny the votes of persons subject thereto, *e.g.*, aliens, infants, or in parliamentary elections peers, &c. But this power has been held not to extend to the incapacity arising from receipt of parochial relief, which here, as before the revision court, enjoys an exceptional position.

The expenses incurred by the overseers in the performance of their registration duties are laid before the revising barrister, whose certificate of allowance signed in open court is final and conclusive. One-half of the amount certified to be due is to be paid out of the poor-rate of the parish; the other half in municipal boroughs out of the borough fund, and elsewhere out of the county fund. The expenses of the clerk of the county council, and the expenses of a town clerk in respect of an area not within a municipal borough, are to be laid before the county council, and the expenses of a town clerk in respect of an area within a municipal borough are to be laid before the town council. The amount allowed by the county council is to be paid out of the county fund; and of the amount allowed by the town council one-half is to be paid out of the borough fund, and one-half to be contributed by the several parishes of the borough out of their poor-rates. The fee of the revising barrister (which is to cover all his expenses) is paid by the Treasury; and one-half of the total amount so paid for each circuit is to be apportioned by a certificate of the Treasury among the counties and boroughs of the circuit, and repaid by them to the Exchequer.

The City of London is not within the Municipal Corporations Acts, and is not subject to the general registration law in the formation of its roll of citizens for municipal purposes. But a register of parliamentary, county, and parochial electors is made in the ordinary way. The universities are also exempt from the general law of registration. At Oxford and Cambridge the members of Convocation and the Senate respectively have always formed the parliamentary constituencies; and, as has been already stated, the registers of those members were before 1832, and still are, the parliamentary registers. Similarly, the Reform Act of 1867, which gave parliamentary representation to the University of London, simply enacted that the register of graduates constituting the Convocation should be the parliamentary register of that body.

Scotland.—In Scotland the qualifications for local government and parish electors are the same as those for parliamentary voters, the only difference in the registers being in respect of personal incapacities for the parliamentary franchise, incapacity for the other franchises by reason of non-payment of rates, and duplicates. The principal Act regulating registration in burghs is 19 and 20 Vict. c. 58, amended in some particulars as to dates by 31 and 32 Vict.

c. 48, § 20. County registration, formerly regulated by 24 and 25 Vict. c. 83, has been assimilated to burgh registration by 48 and 49 Vict. c. 3, § 8 (6). The procedure consists, as in England, of the making and publication of lists of voters, the making of claims and objections, and the holding of revision courts; but there are important differences of detail. Though the parish is the registration unit, parochial machinery is not used for the formation of the register. The parliamentary lists for a county are made up yearly by one or more of the assessors of the county, and those for a burgh by one or more of the assessors for the burgh, or by the clerk of the commissioners. They are published on the 15th of September; and claims and objections must be sent in by the 21st and are published on the 25th of the same month. Publication is made in burghs by posting on or near the town hall, or in some other conspicuous place, in counties by posting the part relating to each parish on the parish church door, and in both cases giving notice by newspaper advertisement of a place where the lists may be perused. The revision is conducted by the sheriff, the time within which his courts may be held being from the 25th of September to the 16th of October, both days inclusive. An appeal lies to three judges of the Court of Session, one taken from each division of the Inner House, and one from the Lords Ordinary of the Outer House. The revised lists are delivered in counties to the sheriff clerk, in burghs to the town clerk, or person to whom the registration duties of town clerk are assigned. The register comes into force for all purposes on the 1st of November.

The municipal register of a royal burgh which is coextensive, or of that part of a royal burgh which is coextensive with a parliamentary burgh, consists of the parliamentary register with a supplemental list of women who but for their sex would be qualified for the parliamentary vote. The municipal register for a burgh, or for that part of one which is not within a parliamentary burgh, consists of persons possessed of qualifications within the burgh which, if within a parliamentary burgh, would entitle them, or but for their sex would entitle them, to the parliamentary vote. The register of county electors consists of the parliamentary register for a county with the supplemental list hereafter mentioned; but inasmuch as exemption from or failure to pay the consolidated county rate is a disqualification for the county electors' franchise, the names of persons so disqualified are to be marked with a distinctive mark on the register; as are also the names of persons whose qualifications are situated within a burgh, such marks indicating that the persons to whose names they are attached are not entitled to vote as county electors. Every third year, in preparation for the triennial elections of county and parish councils (casual vacancies being filled up by co-optation), a supplemental list is to be made of peers and women possessed of qualifications which but for their rank and sex would entitle them to parliamentary votes. The register of county electors in a county and the municipal register in a burgh form the registers of parish electors for the parishes comprised in each respectively. Inasmuch, however, as a man is entitled to be registered as a parish elector in every parish where he is qualified, duplicate entries are, when required, to be made in the register, with distinctive marks to all but one, to indicate that they confer the parish vote only. These distinctive marks and those previously mentioned are to be made in the lists by the assessors, subject to revision by the sheriff. The register is conclusive to the same extent as in England, except that the vote of a parish elector who is one year in arrear in payment of a parish rate is not to be received. The clerk of the parish council is to furnish the returning officer one week before an election with the names of persons so in arrear; and the returning officer is to reject their votes except upon the production of a written receipt. The expenses of registration in counties are to be laid before the county councils; and the amount they allow in respect of the parliamentary register is paid out of the county rate, while the additional amount allowed in respect of the county register is paid by a rate levied on lands and heritages which are not within a burgh. In burghs the expenses are laid before the magistrates or commissioners; and the amount allowed is either apportioned by them among the parishes in proportion to their yearly rent or value, or otherwise levied by rate. Provision is made by 31 and 32 Vict. c. 48, §§ 27-41, for the formation of registers of parliamentary electors for the universities. The register for each university is to be made annually by the university registrar, with the assistance of two members of the council, from whose decisions an appeal lies to the university court.

Ireland.—There are no parish councils in Ireland, and no parochial electors. There are therefore but two registers of voters, the parliamentary and the local government registers, the latter of which consists of the former with a local government supplement containing the names of those excluded from the parliamentary register by reason of their being peers or women, and duplicate entries relating to those whose names are registered elsewhere for the same parliamentary constituency. The principal Acts regulating registration are 13 and 14 Vict. c. 69, 31 and 32 Vict. c. 112, 48 and 49 Vict. c. 17, and 61 and 62 Vict. c. 2. The Lord Lieutenant is empowered to make by Order in Council rules for registration, and to prescribe forms; and under this power has made the Registration (Ireland) Rules, 1899, now in force. The registration unit is not the parish, but the district electoral division, except where such division is subdivided into wards, or is partly within and partly without any town or ward of a borough or town, in which cases each ward of the division or part of a division is a separate registration unit.

The procedure is as follows, subject to variation in cases where there are clerks of unions who held office on the 31st of March 1898, and have not agreed to transfer their registration duties. The clerk of the peace sends out on the 1st of June a precept in the form prescribed for county registration to the secretary of the county council and clerks of urban district councils, together with a copy of the existing register for their county or district; and a precept in the form prescribed for borough registration to town clerks of boroughs. As regards registration units not in a parliamentary or municipal borough, the secretary of the county council or clerk of the urban district council is to put marginal objections, "dead" or "objected," where required, to £10 occupiers and householders in the copy of the register, both in the parliamentary list and in the local government supplement. He is also to make out supplemental parliamentary and local government lists of £10 occupiers and householders not on the existing register, and to put marginal objections where required to these. He is to verify on oath before a magistrate the copy of the register and supplemental lists, and to return them to the clerk of the peace by the 8th of July. As regards registration units in a parliamentary borough, but outside a municipal borough, the secretary of the county council or clerk of the urban district council is to make out lists of £10 occupiers and householders with local government supplement, and transmit them to the town clerk of the municipal borough or town. The clerk of the peace is to publish the copy of the register, after himself placing marginal objections where required to voters other than £10 occupiers and householders, and the supplemental lists as received, and also the corrupt and illegal

practices list, if any, on the 22nd of July. On the same day the town clerk will publish the lists received as aforesaid for registration units outside the municipal borough, and the lists, which he will have made out himself for the municipal borough, including the freemen's list and corrupt and illegal practices list. Freemen being entitled to the local government vote will, if resident, be placed on the list of the registration unit where they reside, and will, if non-resident, be allotted by the revising barrister among the registration units of the borough for local government purposes in proportion to the number of electors in each registration unit. Claims are to be sent in to the clerk of the peace and town clerk by the 4th of August, including old lodger claims and, in the case of the clerk of the peace, ownership claims. Lists of claimants with marginal objections, where required, are to be published by the clerk of the peace and town clerk by the 11th of August. Notices of objection to voters or claimants may be given by the 20th of August; and lists of persons objected to are to be published by the clerk of the peace and town clerk by the 24th of the same month. Publication of lists and notices by a clerk of the peace is made by posting copies of those relating to each registration unit outside every court-house, petty sessions court, and other public offices in the unit; publication by a town clerk is made by posting copies outside the town hall, or, if there be none, in some public and conspicuous place in the borough.

Revising barristers are specially appointed for the county and city of Dublin by the Lord Lieutenant; elsewhere the county court judges and chairmen of quarter sessions act as such *ex officio*, assisted, when necessary, by additional barristers appointed by the Lord Lieutenant. The time for the holding of revision courts is from the 8th of September to the 25th of October inclusive. An appeal lies to the Court of Appeal, whose decision is final. The revised lists are handed to the clerk of the peace; they are to be made up by him by the 31st of December, and come into force on the 1st of January. The registration expenses of the clerk of the peace are to be laid before the county council, and the amount allowed is to be levied from the county. The expenses of the town clerk are to be laid before the revising barrister; and the amount allowed by the barrister is to be laid before the county council, who may allow the whole or part of such amount, and levy the sum they allow from the county. In county boroughs the council of the borough acts in the place of the county council. The extra cost, if any, incurred by the Treasury in connexion with revision in consequence of the creation of the local government register, is to be certified by the Treasury, and repaid to the Exchequer by the county councils.

The registrar of the University of Dublin is to make out in December a list of the persons entitled to the parliamentary vote for the university, and to print the same in January, and to publish a copy in the university calendar, or in one or more public journals circulating in Ireland. He is to revise the list annually, and expunge the names of those dead or disqualified; but an elector whose name has been expunged because he was supposed to be dead is entitled, if alive, to have his name immediately restored and to vote at any election. (L. L. S.)

Regla, an important suburb of Havana, opposite the city, on the east side of the bay, where most of the sugar warehouses of the Havana trade are situated, and where outgoing ships are laden. The eastern railways have their termini here. Formerly it was the scene of the Havana bull-fights. The population in 1899 was 11,363.

Reichenbach, a town of Germany, 11 miles by rail south-west of the town and in the circle of Zwickau, kingdom of Saxony. There are a commercial and a weaving school, and a museum; the industries include woollen, cotton, bleaching, cloth-dressing, spinning, wool-carding, and wool-dressing mills, aggregating in all about 150 firms. Population (1885), 18,406; (1900), 24,498.

Reichenberg (Czech, *Liberec*), a town of Bohemia, Austria, near the Saxon and Prussian frontiers, and practically the capital of German Bohemia. After Prague, it is one of the largest and most important centres of trade and industry in the crownland, although within the last decade the population of Pilsen and Aussig show a more rapid increase. Population (1890), 30,890; (1900), 34,204, chiefly German and Catholic (estimated at 5 per cent. Czech, 4 per cent. Protestant, and 3 per cent. Jewish). The garrison has been increased to 1518 men. In 1890 the district within the jurisdiction of the Chamber of Commerce comprised over 370 factories for spinning and weaving of wool, cotton, and linen, besides carpet factories and establishments for the manufacture of carding and other machinery, beer, malt, liqueurs, hosiery, dyeing, &c. The industrial community, including a considerable section of the large manufacturers, has manifested strong German-Nationalist sentiment in the recent phases of the nationality strife in Austria.

Reid, Sir George (1841–——), Scottish artist, was born in Aberdeen. After the usual school education he developed an early passion for drawing, which led to his being apprenticed in 1854 for seven years to Messrs Keith and Gibb, lithographers in Aberdeen. In 1861 Reid took lessons from an itinerant portrait-painter, William Niddrie, who had been a pupil of James Giles, R.S.A., and afterwards entered as a student in the school of the Board of Trustees in Edinburgh. After the usual course of study Reid returned to Aberdeen, to paint landscapes and portraits for any trifling sum which his work could command, gradually gaining the notice of those who recognized his earnestness. The first portrait to attract attention, from its fine quality, was that of George Macdonald, the poet and novelist, now the property of the University of Aberdeen. His early landscapes were conscientiously painted in the open air and on the spot. But Reid soon came to see that such work was inherently false, painted as the picture was day after day under varying conditions of light and shade. Accordingly, in 1865 he proceeded to Utrecht to study under A. Mollinger, whose work he admired, from its unity and simplicity. This change in his method of viewing Nature was looked on as revolutionary by the Royal Scottish Academy, and for some years his work found little favour in that quarter; but other artists gradually adopted the system of tone-studies, which ultimately prevailed. Conscious of imperfect training in drawing, Reid went to Paris in 1868 to study under the accomplished figure-painter Yvon; and, still further to master the mysteries of his art, he worked in 1872 with his friend Josef Israëls at The Hague. From this time forward Reid's success was continuous and marked. He showed his versatility in landscape, as in his "Whins in Bloom," which combined great breadth with fine detail; in flower-pieces, such as his "Roses," which were brilliant in rapid suggestiveness and force; but most of all in his portraits, which are marked by great individuality, and by fine insight into character. His work in black-and-white, his admirable illustrations in brush-work of Edinburgh and its neighbourhood, and also his pen-drawings, about which it has been declared that "his work contains all the subtleties and refinements of a most delicate etching," must also be noted. Elected Associate of the Royal Scottish Academy in 1870, Reid attained the full membership in 1877, and took up his residence in

Edinburgh in 1882. In 1891 he was elected President, receiving also the honour of knighthood, and he was awarded a gold medal at the Paris Exhibition of 1900. For a specimen of his work, see PORTRAITURE.

Reigate, a municipal borough and market town of Surrey, England, in the Reigate parliamentary division, 23 miles south of London, with a station on the South-Eastern Railway. The Free Convalescent Home, removed from Bletchingly, was opened at South Park in 1880; and Brabazon Home, in connexion with the Girls' Friendly Society, in 1885. There is also a technical institute. Population (1881), 18,665; (1901), 25,993.

Reinecke, Carl Heinrich Carsten (1824–——), German composer and pianist, born at Altona, 23rd June 1824, came of musical stock, his father, Peter Reinecke (who was also his teacher), being an admirable musician. At the age of eleven he made his first appearance as pianist, and when scarcely eighteen he went a successful tour through Denmark and Sweden. After a stay in Leipzig, where he studied under Mendelssohn, in the recently founded Conservatorium, and Schumann, Reinecke went on tour with Königslöw and Wasielewski, Schumann's biographer, in North Germany and Denmark. From 1846 to 1848 Reinecke was court pianist to Christian VIII. of Denmark. After resigning this post he went first to Paris, and next to Cologne, as professor in the Conservatorium. From 1854 to 1859 he was music director at Barmen, in the latter year filling this post at Breslau University; in 1860 he became conductor of the famous Leipzig Gewandhaus, a post which (together with that of professor at the Conservatorium) he held with honour and distinction for thirty-five years. During this time Reinecke continually made concert tours to England and elsewhere. His pianoforte playing belonged to a school now almost extinct. Grace and neatness were its characteristics, and at one time Reinecke was probably unrivalled as a Mozart player and an accompanist. His compositions are as unimportant historically as Raff's, and even more numerous. His grand opera *König Manfred*, and the comic opera *Auf hohen Befehl*, were at one time frequently played in Germany; and his cantata *Hakon Jarl* is melodiously beautiful, as are many of his songs; while his Friedensfeier overture was once quite hackneyed. By far his most valuable works are those written for educational purposes. His sonatinas, his "Kindergarten," and much that he has ably edited, will continue to delight generations not yet born.

Reinkens, Joseph Hubert (1821–1896), Old Catholic bishop, was born at Burtscheid, near Aix-la-Chapelle. He was educated at the gymnasium at Aix, and afterwards studied theology at the universities of Bonn and Munich. He was ordained priest in 1848, and in 1849 graduated as doctor in theology with considerable *éclat*. He was soon appointed professor of ecclesiastical history at Breslau, by the influence of the Cardinal Archbishop Diepenbrock. In 1865 he was made rector of Breslau University. He wrote a number of treatises on various subjects during this period, the most noticeable among which were monographs on Clement of Alexandria, Hilary of Poitiers, and Martin of Tours. In consequence of an essay on art, especially in tragedy, after Aristotle, he was made doctor in philosophy in the University of Leipzig. When, in 1870, the question of Papal Infallibility was raised, Reinkens attached himself to the party opposed to the proclamation of the dogma. He had been confirmed in his Liberal sentiments by a visit he had recently paid to Rome. He threw himself vigorously into the controversy, and wrote several pamphlets on Church tradition relative to Infallibility, and on the procedure of the Council. When the dogma of Infallibility was proclaimed, Reinkens joined those who resolved to offer an organized resistance to the decree. The head of this band of influential theologians was Döllinger, and among them were von Schulte, Michelis, Friedrich, Knoodt, Langen, and Weber. Reinkens was one of those who signed the celebrated Declaration of Nuremberg in 1871. It was further resolved to appeal to other Episcopal bodies; and at the Bonn conferences with Orientals and Anglicans, organized by Döllinger in 1874 and 1875, Reinkens was a conspicuous figure. In the meantime the question had to be decided whether the Old Catholics should or should not definitely separate themselves from the Church of Rome. The bishops of the so-called Jansenist Church in Holland, which had existed independently of Rome for about two centuries, and possessed an incontestably canonical Episcopate, had promised to convey a valid succession according to the customs of the Western Church. Döllinger objected; and though he afterwards admitted that his objections were ill-founded, his dissent prevented all but a small band of eminent theologians and a few enthusiastic laymen from joining the new Church. It was nevertheless constituted, and Reinkens was chosen bishop of the Old Catholics in Germany at an enthusiastic meeting at Cologne in 1873. On the 11th August of the same year he was consecrated to the Episcopate by Dr Heykamp, bishop of Deventer, in Holland, Archbishop Loos of Utrecht, who had promised to consecrate the bishop if elected by the German Old Catholics, having been removed by death on the very day of Reinkens's election to the Episcopate. Reinkens devoted himself to his office of superintending the infant Church with the utmost solicitude, as the number of his *Hirtenbriefe* and the variety of their subjects prove. Nor did his activity as a theologian cease. He wrote a number of theological works after his consecration, but none of them so important as his treatise on Cyprian and the Unity of the Church, which he wrote in the year of his consecration. The chief act of his episcopal career was his consecration in 1876 of Dr Edward Herzog to preside as bishop over the Old Catholic Church in Switzerland. He would have performed the same office for the Old Catholics in Austria, but the Austrian Government interfered and refused its consent. In 1881 Reinkens visited England, and received Holy Communion more than once with bishops, clergy, and laity of the Church of England. Almost his last important public act was the publication, in conjunction with Professor Friedrich, of a defence of the validity of Anglican orders against his co-religionists, the Old Catholics of Holland, who had distributed an attack on their validity among the clergy and theologians present at the Old Catholic Congress at Rotterdam in 1894. Reinkens was gentle and inoffensive in disposition; and if he was unable to command much support for the Church over which he presided, he won for himself great respect and affection among the German people. This was manifested at his funeral, when a great and sympathetic crowd lined the streets through which the *cortège* had to pass, and wreaths from the sons of the German emperor were laid upon the coffin. He died at Bonn on 4th January 1896. (J. J. L*.)

Remedios, a large town of Santa Clara province, Cuba. The population in 1899 was 6633.

Remscheid, a town of Prussia, Rhine province, 6 miles by rail south from Barmen, a centre for the manufacture of cutlery and steel and iron wares. The municipal area was enlarged in 1893. Population (1885), 33,986; (1900), 58,108.

Renaix, a town of Belgium, in the province of East

Flanders, 25 miles south of Ghent, on a network of railways. It has dye-works, bleaching-fields, and manufactories for cotton and woollen goods. Population (communal) (1880), 14,370; (1900), 19,936.

Renan, Ernest (1823–1892), the celebrated French thinker and writer, was born on the 28th of February 1823 in the town of Tréguier, situated in the department of the Côtes-du-Nord, which occupies the north-west of the ancient province of Brittany. His father's people were of the fisher-clan of Renans or Ronans; his grandfather, having made a small fortune by his fishing smack, bought a house at Tréguier and settled there, and this man's son, captain of a small cutter and an ardent Republican, married the daughter of Royalist trading-folk from the neighbouring town of Lannion. All his life long Renan's mind was divided between his father's and his mother's political beliefs. His father died when the child was five years old. His sister Henriette, twelve years older than Ernest, a girl of remarkable character, was henceforth morally the head of the household. She determined to pay her father's debts, to help her mother, and to educate her little brother. Having in vain attempted to keep a school for girls at Tréguier, she left her native place and went to Paris as teacher in a young ladies' boarding-school. Ernest meanwhile was educated in the ecclesiastical seminary of his native place. His family still preserve his good-conduct notes for this period: "Docile, patient, diligent, painstaking, thorough," are adjectives which occur often. We do not hear that he was brilliant or clever, but then the priests cared little for such qualities; occasionally they complain that "Ernest Renan is inattentive during service in church." While the priests were grounding Renan in mathematics and Latin, and teaching him the value of disinterestedness and duty, his mother, with her fund of myth and local traditions, completed his education at home. Very early in life the future historian of religions learned how the unexplained becomes the supernatural in a rustic imagination, and how a fact becomes a faith. Madame Renan *mère*, a lively little gipsy of a woman, was only half a Breton. Her paternal ancestors came from Bordeaux, and Renan used to say that in his own nature the Gascon and the Breton were constantly at odds.

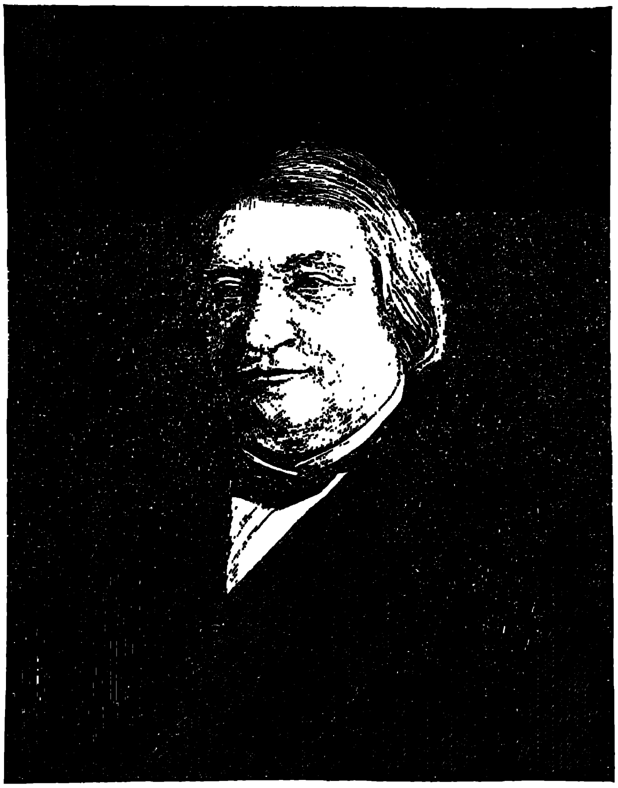
In the summer of 1838 Renan carried off all the prizes at the college of Tréguier. His sister in Paris told the doctor of the school in which she taught about the marvellous success of her brother, and he carried the news to M. Dupanloup, then engaged in organizing the ecclesiastical college of St Nicholas du Chardonnet, a school in which the young Catholic nobility and the most gifted pupils of the Catholic seminaries were to be educated together, with a view to cementing the bond between the aristocracy and the priesthood. When M. Dupanloup heard of the new Breton prodigy, he sent for him at once. Renan was fifteen and a half. He had never been outside his Breton province. "What I saw in Paris was as strange to me as if I had been sent into the wilds of Tahiti or Timbuctoo." The breath of the boulevards penetrated through a thousand fissures into the closed circle of the Parisian seminary, where the students discussed with passion the rising glories of Lamartine, Victor Hugo, and Michelet. "I learned with stupor that knowledge was not a privilege of the Church . . . I awoke to the meaning of the words talent, fame, celebrity." Above all, religion seemed to him a wholly different thing in Tréguier and in Paris. The superficial, brilliant, pseudo-scientific Catholicism of the capital did not satisfy the new recruit, who had accepted the austere and primitive faith of his Breton masters.

In 1840 Renan left St Nicholas to study philosophy at the seminary of Issy, in the suburbs of Paris. He entered with a passion for Catholic scholasticism. The rhetoric of St Nicholas had wearied him, and his serious intelligence hoped to satisfy itself with the vast and solid material of Catholic theology. Reid and Malebranche first attracted him among the philosophers, and after these he opened the tomes of Hegel, Kant, and Herder: "I studied the Germans, and I thought I entered a temple." But it was not that temple of which Issy is a portal. Renan began to perceive the essential contradiction between the metaphysics which he studied and the faith that he professed, but a curious appetite for truths that can be verified restrained his scepticism. "Philosophy excites and only half satisfies the appetite for truth; I am eager for mathematics," he wrote to his sister Henriette, his confidante, his guide, and friend. The letters had far to go. Bent on her self-imposed charges, Henriette had accepted in the family of Count Zamoyski an engagement more lucrative than her place as under-mistress in a Paris boarding-school. From her Polish steppes she exercised the strongest influence over her distant brother. All that Jacqueline Pascal was to the great French reformer Henriette was to Ernest Renan, and her recently published letters reveal a mind almost equal, a moral nature superior, to his own. It was not mathematics but philology which was to settle the gathering doubts of Ernest Renan. His course completed at Issy, he entered the great college of St Sulpice in order to take his degree in philology prior to entering the Church. And here he began the study of Hebrew. His mind, hitherto nourished on dogmas and ideas, on views and opinions, was famished for reality and alert in detecting the importance of a fact. He was already prompt to accept the proofs of experience as the sole authentic proofs. He saw that the second part of Isaiah differed from the first not only in style but in date; that the grammar and the history of the Pentateuch are posterior to the time of Moses; that the book of Daniel is clearly apocryphal. It followed from his training that, if you admit one error in a revealed text, you incriminate the whole. Secretly, Renan felt himself cut off from the communion of saints, and yet with his whole heart he desired to live the life of a Catholic priest. "The priest lives for his fellows, to teach them and to counsel them. He is a man of books; he lives the contemplative life, and yet he is a brother unto his brethren . . . I am not born for a life of action; a merely private life would seem to me a sort of selfishness . . . I am only fit for *one* sort of life." Hence a bitter struggle between vocation and conviction; owing to Henriette, conviction gained the day. In October 1845 Renan left the seminary of St Sulpice for Stavistas, a lay college of the Oratorians. Finding himself even there too much under the domination of the Church, a few weeks later, most reluctantly, he broke the last tie which bound him to the religious life and entered M. Crouzet's school for boys as a pupil teacher—or, rather, as usher—receiving his board and his room in return for his supervision of the evening class.

It is always dangerous to educate a really great mind in only one order of truth; so soon as it perceives the hidden half of the world, it will realize and even magnify its importance, embracing it with the ardour of a spiritual conversion. Thus Pascal, trained by a set of savants to observe, to calculate, to reason, to concern himself solely with experiments and mechanical inventions, was to become the tormented enthusiast of the religious life. Renan, brought up by priests in a world ruled by authority and curious only of feeling and opinion, was to accept the scientific ideal with the same extraordinary expansion of all his faculties. He was henceforth and for ever ravished by the splendour of the cosmos. Quite at the end of his life he wrote of Amiel, "The man who has time to keep a private diary has

never understood the immensity of the universe." The magnificent certitudes of physical and natural science were revealed to Renan in 1846 by the great chemist Marcellin Berthelot, then a boy of eighteen, his pupil at M. Crouzet's school. To the day of Renan's death their friendship continued. "It consisted in what we learned together." M. Crouzet's usher was occupied only in the evenings. In the daytime Renan continued his researches in Semitic philology. In 1847, an obscure young man of four-and-twenty, he obtained the Prix Volney—one of the principal distinctions awarded by the Academy of Inscriptions—for the manuscript of his "General History of Semitic Languages." In 1847 he took his degree as Agrégé de Philosophie; that is to say, fellow of the university, and was offered a place as master in the lycée of Vendôme. In 1848 a small temporary appointment to the lycée of Versailles permitted him to return to the capital and resume his studies.

The revolution of 1848 aroused in Renan that side of him which loved the priesthood because "the priest lives for his fellows." For three years the problems of faith and the glories of science had filled his mind and soul, to the exclusion of this sense of fraternity, which was, none the less, fundamental, and was yet to inspire some of his most beautiful pages. Among the gun-smoke and the fusillades of 1848 Renan for the first time confronted the problems of Democracy. The result was an immense volume, *The Future of Science*, which was to remain in manuscript until 1890. *L'Avenir de la Science* is an attempt to conciliate the privileges of a necessary *élite* with the diffusion of the greatest good of the greatest number. This difficulty was to haunt Ernest Renan throughout his life. By the time he had finished his elaborate scheme for regenerating society by means of a devoted aristocracy of knowledge, and the diffusion of culture, the year 1848 was past and gone, and with it his fever of Democracy. In 1849 the French Government sent the young scholar to Italy on a scientific mission. He remained eight months abroad, during which he forgot his anxiety about the toilers' lot. Hitherto he had known nothing of art. In Italy the artist in him awoke, and easily triumphed over the savant and the reformer. On his return to Paris Renan chose a small flat near the Val-de-grace, and went to live there with his sister Henriette, his devoted secretary. A small post at the National Library, together with his sister's savings, henceforth furnished him with the means of livelihood. In the evenings he wrote for the *Revue des Deux Mondes* and the *Débats* those exquisite essays, some of the most perfect he was to produce, which were to appear in 1857 and 1859 under the titles *Études d'Histoire Religieuse* and *Essais de Morale et de Critique*. Already in 1852 his book on *Averroès* had brought him not only his doctor's degree, but his first reputation as a thinker. In his two volumes of essays Renan shows himself a Liberal, but no longer a Democrat. Nothing, according to his philosophy, is less important than prosperity. The greatest good of the greatest number is a theory as dangerous as it is illusory. Man is not born to be prosperous, but to realize, in a little vanguard of chosen spirits, an ideal superior to the ideal of yesterday. Only the few can attain a complete development. The bulk of humanity lives by proxy; it is the enormous useless residue from which is distilled that small drop of exquisite aroma—the *élite*. Yet there is a solidarity between the chosen few and the masses which produce them; each has a duty to the other. The acceptance of this duty is the only foundation for a moral and just society. The aristocratic idea has seldom been better stated.



Ernest Renan.

(*From a photograph by A. Liébert, Paris.*)

The success of the *Études d'Histoire Religieuse* and the *Essais de Morale* had made the name of Renan known to a cultivated public. While Mademoiselle Renan remained shut up at home copying her brother's manuscripts or compiling material for his work, the young philosopher began to frequent more than one Parisian *salon*, and especially the studio of Ary Scheffer, at that time a noted social centre. In 1856 he proposed to marry Mademoiselle Cornélie Scheffer, the niece and adopted daughter of the great Dutch painter. Not without a struggle did the devoted but jealous Henriette resign her claim to be her brother's sole companion. At last she consented not only to the marriage, but to make her home with the young couple, whose housekeeping depended on the sum that Mademoiselle Renan could contribute. The history of this humble romance has been told by Ernest Renan, with rare tenderness and beauty, in the memorial essay which he wrote some six years later, entitled *Ma Sœur Henriette*. His marriage brought much brightness into his life, a rare naturalness and piquancy into his style, and a greater attention to the picturesque, as if at last he dared to be altogether himself, even at the expense of a certain noble simplicity. He did not forsake his studies in Semitic philology, and in 1859 appeared his translation of the *Book of Job* with an introductory essay, followed in 1859 by the *Song of Songs*.

Renan was now a candidate for the chair of Hebrew and Chaldaic languages at the Collège de France, a chair which he had consistently desired since first he studied Hebrew at the seminary of St Sulpice. The death of the famous scholar Quatremère had left this post vacant in 1857. No one in France save Renan was capable of filling it. The Catholic party, upheld by the empress, would not appoint an unfrocked seminarist, a notorious heretic, to what is, in point of fact, a chair of Biblical exegesis. Yet the emperor, ever anxious to stand well with men of letters and men of science, wished to conciliate Ernest Renan. He offered to send the young scholar on an archæological mission to Phœnicia. Renan

immediately accepted. Leaving his wife at home with their baby son, Renan left France, accompanied by his sister, in the summer of 1860. Madame Renan joined them in January 1861, returning to France in the course of July. Her husband and her sister-in-law would have done well to accompany her. But the mission proved fruitful in Phœnician inscriptions which Renan was to publish in his *Mission de Phénicie*. They form the base of that *Corpus Inscriptionum Semiticarum* on which, a little perversely, he used in later years to declare that he founded his claim to remembrance. He wished to complete his exploration of the upper range of Lebanon; he remained, therefore, with Henriette to affront the dangerous miasma of a Syrian autumn. At Amschit, near Byblos, Henriette Renan died of intermittent fever on the 24th September 1861. Her brother, himself at death's door, was carried unconscious on board a ship waiting in harbour and bound for France. The sea air revived him, but he reached France a broken man apparently in heart and health. Fortunately, he had more than one great project which attached him to life. His sister in her last days had entreated him not to give up his candidature for the chair of Hebrew, and on the 11th of January 1862 the Minister of Public Instruction ratified Renan's election to the post. But the scandal of his opening lecture, in which, amid the applause of the students, Renan declared Jesus Christ "an incomparable Man," alarmed the Catholic party. Renan's lectures were pronounced a disturbance of the public peace, and the young professor was forthwith suspended from his functions. On the 2nd of June 1864, on opening the morning newspaper, Renan saw that he had been transferred from the chair of Hebrew at the College of France to the post of sub-librarian at the National Library. The fund of combativeness, which even the most detached philosopher hides in the bottom of his heart, seethed within him at this high-handed proceeding. He wrote to the Minister of Public Instruction: "Pecunia tua tecum sit!" He refused the new position, was officially deprived of his chair, and henceforth depended for his daily bread solely upon his pen.

Henriette had told him not to abandon the chair of Hebrew. She had also said, "Write the life of Jesus." They had, in fact, begun it together in their Syrian retreat, she copying the pages as fast as her brother wrote them, with a New Testament and a *Josephus* for all his library. The book bears the mark of its origin — it is filled with the living, vibrating atmosphere of the East. It is the work of a man familiar with the Bible and theology, and no less acquainted with the inscriptions, monuments, types, and landscapes of Syria; it is, above all, the work of a man who has sounded the human heart. But it is scarcely the work of a great scholar: Renan's debt to the school of Tübingen has certainly been exaggerated, in so far at least as regards the *Life of Jesus*. The book appeared on the 23rd June 1863; before November sixty thousand copies of it were in circulation. There was no longer any doubt as to Ernest Renan's future. The professor had become a great writer, the philologist was seen to be a genius. But Renan still used his literary gifts to pursue a scientific ideal. In the days when he had composed his huge, immature treatise on the *Future of Science*, he had written: "I envy the man who shall evoke from the past the origins of Christianity. Such a writer would compose the most important book of the century." He set to work to realize this project, and produced the *Apostles* in 1866, and *St Paul* in 1869, after having visited Asia Minor with his wife, where he studied the scenes of the labours of St Paul as minutely as in 1861 he had observed the material surroundings of the life of Jesus.

Renan was not only a scholar. In *St Paul*, as in the *Apostles*, he shows his deep concern with the larger social life, his sense of fraternity, and a revival of the Democratic sentiment which had inspired *L'Avenir de la Science*. In 1869 he presented himself as the candidate of the Liberal opposition at the parliamentary election for Meaux. While his temper had become less aristocratic, his Liberalism had grown more tolerant. On the eve of its dissolution Renan was half prepared to accept the Empire, and, had he been elected to the Chamber of Deputies, he would have joined the group of *l'Empire Libéral*. But he was not elected. A year later war was declared with Germany, the Empire fell, and Napoleon III. went out into exile. The Franco-German war was to be a turning-point in Renan's history. Germany had always been to him, as he had exclaimed at St Sulpice, a sanctuary, "un temple," the asylum of thought and disinterested science. Now he saw the land of his ideal destroy and ruin the land of his birth; he beheld the German no longer as a priest, but as a brutal and wanton invader. With a great revulsion his heart turned to France. In his noble and thoughtful work, *La Réforme Intellectuelle et Morale* (1871), he endeavoured at least to bind her wounds, to raise her head, to safeguard her future. Yet, in spite of himself, he was still under the influence of Germany. The ideal and the discipline which he proposed to his defeated and mangled country were the ideal and the discipline of her conqueror —a feudal society, a monarchical government, a France directed by a superior class, an *élite*, which the rest of the nation exists merely to support and nourish; an ideal of honour and duty imposed by a chosen few on the recalcitrant and subject multitude. The savage and ignorant errors of the Commune confirmed Renan in this reaction. At the same time the note of irony, always perceptible in his work, grows more bitter, more concentrated, more brilliant. His *Dialogues Philosophiques*, written in 1871, his *Ecclesiastes* (1882), and his *Antichrist* (1876) (the fourth volume of the *Origins of Christianity*, dealing with the reign of Nero), are incomparable in their literary genius, but they are examples of a disenchanted and sceptical temper. He had vainly tried to make his country follow his precepts. He resigned himself to watch her drift her own way, probably, as it seemed to him, towards perdition. The progress of events showed him, on the contrary, a France which every day left a little stronger, and he aroused himself from his disbelieving, disillusioned mood, and observed with genuine interest the struggle for justice and liberty of a Democratic society. For his mind was the broadest of the age, incapable of blindly taking a side, of setting a limit to the laws of reason. And when Truth spoke from the mouth of an opponent he was ever ready with an unqualified assent. The fifth and sixth volumes of the *Origins of Christianity* (the *Christian Church* and *Marcus Aurelius*) show us a Renan reconciled with Democracy, confident in the gradual ascent of man, aware that the greatest catastrophes do not really interrupt the sure if imperceptible progress of the world—reconciled also in some measure, if not with the truths, at least with the moral beauties of Catholicism and with the remembrance of his pious youth.

On the threshold of old age, the philosopher turned and cast a last long lingering glance at the days of his childhood. He was nearly sixty when, in 1883, he published those *Souvenirs d'Enfance et de Jeunesse*, which, after the *Life of Jesus*, are the work by which he is chiefly known. They took the world by storm. They possess that lyric note of personal utterance which the public prizes in a man already famous. They showed the *blasé* modern reader that a world no less poetic, no less primitive than that of the *Origins of Christianity* exists, or

still existed within living memory, on the north-western coast of France. They have the Celtic magic of ancient romance and the simplicity, the naturalness, the accent of veracity which the 19th century prized so highly. They reflect the picturesque and emotional side of Renan, the easiest to understand in that mind of many facets. But his *Ecclesiastes*, published a few months earlier, his *Drames Philosophiques* collected in 1888, give a more adequate image of his fastidious, subtle, critical, most disenchanted, yet not unhopeful spirit. These books are often bitter and melancholy, yet not destitute of traces of optimism. They show the attitude towards uncultured Socialism of a philosopher Liberal by conviction, by temperament an aristocrat. We learn in them how Caliban (Democracy), the mindless brute, educated to his own responsibility, makes after all an adequate ruler; how Prospero (the aristocratic principle, or, if we will, the mind) accepts his dethronement for the sake of greater liberty in the intellectual world, since Caliban proves an effective policeman, and leaves his superiors a free hand in the laboratory; how Ariel (the religious principle) acquires a firmer hold on life, and no longer gives up the ghost at the faintest hint of change. Indeed, Ariel flourishes in the service of Prospero under the external government of the many-headed brute. For the one thing needful is not destined to succumb. Religion and knowledge are as imperishable as the world they dignify. Thus out of the depths rises unvanquished the essential idealism of Ernest Renan.

Renan was a great worker. At sixty years of age, having finished the *Origins of Christianity*, he began his *History of Israel*, based on a lifelong study of the Old Testament and on the *Corpus Inscriptionum Semiticarum*, published by the Académie des Inscriptions under Renan's direction from the year 1881 till the end of his life. The first volume of the *History of Israel* appeared in 1887, the third and finest volume in 1891, the last two only after the historian's decease. As a history of facts and theories the book has many faults; as an essay on the evolution of the religious idea, it is (despite some passages of frivolity, irony, or incoherence) of extraordinary importance; as a reflection of the mind of Ernest Renan it is the most lifelike of images. In a volume of collected essays, *Feuilles Détachées*, published also in 1891, we find the same mental attitude, an affirmation of the necessity of piety independent of dogma: "the most logical attitude of the thinker towards religion is to behave as though religion were true." Renan had never been strong, and the last years of his life were much chequered by rheumatism, which gradually affected the structure of the heart. On the 12th of October 1892 he died after a few days' illness. "I have done my work," he said to Madame Renan; "I die happy." Dead, he continued to delight his readers. Two volumes of the *History of Israel*, his correspondence with his sister Henriette, his *Letters to M. Berthelot*, and the *History of the Religious Policy of Philippe-le-Bel*, which he wrote in the years immediately before his marriage, all appeared during the last eight years of the 19th century. (A. M. F. D.)

Renfrew, a royal and parliamentary burgh (Kilmarnock group) and the county town of Renfrewshire, near the Clyde, about 6 miles west of Glasgow by road. A large dock is about to be constructed by the Clyde Trust at a cost of £335,000. Two engineering works, cabinet-making factories, and large bolt and rivet undertakings are new industrial features. The construction of dredgers and floating docks is a speciality connected with the staple industry, shipbuilding. The school board manages a grammar school, and has recently built a new elementary school. Population (1881), 4825; (1901), 9297.

Renfrewshire, a maritime county of west Scotland, is bounded N. by the Clyde, N.E. by Dumbartonshire and Lanarkshire, E. by Lanarkshire, S. by Ayrshire, and W. by the Firth of Clyde.

Area and Population.—In 1891 the Renfrewshire part of the city of Glasgow was transferred to the county of Lanark, as was the Renfrewshire police burgh of Kinning Park; the whole of the parish of Cathcart was placed in Renfrewshire, and the whole parish of East Kilbride in Lanarkshire; while the parishes of Beith and Dunlop, which had been previously divided between Ayrshire and Renfrewshire, were placed wholly in the former county. According to the latest official estimate, the area of the county (foreshore excluded) is 155,965 acres, or about 244 square miles. The population was, in 1881, 263,374; in 1891, 290,798; in 1891, on the above area, 230,812, of whom 110,520 were males and 120,292 females; in 1901, 268,934. On the old area, taking land only (156,785 acres, or 245 square miles), the number of persons to the square mile in 1891 was 1187, and the number of acres to the person 0·5. In the registration county the population increased between 1881 and 1891 by 8·7 per cent. Between 1881 and 1891 the excess of births over deaths was 31,459, and the increase of the resident population 19,571. The following table gives particulars of births, deaths, and marriages in 1880, 1890, and 1899:—

Year.	Deaths.	Marriages.	Births.	Per cent. of Illegitimate.
1880	5239	1636	7730	6·2
1890	4861	1778	7842	5·08
1899	5291	2010	8548	4·1

The following table gives the birth-rate, death-rate, and marriage-rate per thousand of the population for a series of years:—

	1880.	1881–90.	1890.	1891–98.	1899.
Birth-rate	34·64	34·57	32·18	31·92	32·68
Death-rate	23·48	21·21	19·94	19·99	20·22
Marriage-rate	7·33	7·31	7·29	7·05	7·68

At the census of 1891 there were 6114 Gaelic-speaking persons in the county, of whom 51 spoke Gaelic alone, and 2411 foreigners. Valuation in 1889–90, £783,051; 1899–1900, £612,633.

Administration.—Since 1885 the county has returned two members to Parliament, one for the East and the other for the West division of the shire. Paisley (79,355), Greenock (67,645), Port-Glasgow (16,840), and Renfrew (9297) are all parliamentary burghs, Paisley and Greenock having a member each, and the other two belonging to the Kilmarnock group. Renfrew, the county town, is the only royal burgh. Police burghs are Barrhead (9855), Pollokshaws (11,169), Gourock (5244), and Johnstone (10,502). There are 16 civil parishes, and the number of paupers and dependants in September 1899 was 5386; there are poor-houses at Greenock and Paisley. Renfrewshire forms a sheriffdom with Bute, and there is a resident sheriff-substitute at Paisley and one at Greenock.

Education.—Twenty-three school boards manage 81 schools, which had an average attendance of 34,638 in 1898–99, while 22 voluntary schools (17 Roman Catholic and 2 Episcopal) had 6395. There is an academy at Greenock, and a grammar school and a technical school at Paisley; five other schools in the county earned grants in 1898 for giving higher education; while the county secondary committee makes provision also for the free education of Renfrewshire children in Glasgow high schools and the Spier School at Beith. The Paisley Technical School and the Glasgow and West of Scotland Technical College are subsidized out of the residue grant, part of which goes also to defraying the travelling expenses of students and to supporting science and art and technological classes in the burghs and throughout the county.

Agriculture.—The percentage of the area under cultivation was, in 1898, 59 per cent. Arable farming predominates, but dairying grows with the increasing town populations in and adjoining the county. The following table gives the principal acreages at intervals from 1880:—

Year.	Area under Crops.	Corn Crops.	Green Crops.	Clover.	Permanent Pasture.	Fallow.
1880	93,786	17,477	8095	17,332	50,355	527
1885	95,529	16,806	6670	23,573	48,268	212
1890	96,247	15,573	6015	29,501	44,986	102
1895	93,907	14,078	5951	21,437	52,216	134
1899	92,695	13,322	5858	24,773	48,551	90

The table in the next column gives particulars of the live stock during the same years.

Year.	Total Horses.	Total Cattle.	Cows or Heifers in Milk or in Calf.	Sheep.	Pigs.
1880	3330	24,677	14,945	35,436	1192
1885	3296	27,619	16,131	32,432	1815
1890	3470	27,878	17,247	36,667	1541
1895	3516	26,125	16,808	38,370	1584
1899	3314	26,813	17,452	42,584	1458

There were 6661 acres under wood in 1895. Of the 1096 holdings in 1895, the date of the last return, the average size was 86 acres. The percentage under 5 acres was 12·13, between 5 and 50 acres 27·92, and over 50 acres 59·95. The number of farms between 50 and 100 acres was 295, between 100 and 300, 342, between 300 and 500, 14 only, and there were 6 over 500.

Industries and Trade.—Industries have advanced generally in importance throughout the county, but no change has taken place in their fundamental character. For details see the separate articles on Johnstone, Pollokshaws, Barrhead, Kilbarchan, Paisley, Greenock, and Renfrew. The following table shows the output of coal, ironstone, fireclay, and sandstone in 1890 and 1899:—

Year.	Coal.		Ironstone.		Fireclay.		Sandstone.	
	Tons.	Value.	Tons.	Value.	Tons.	Value.	Tons.	Value.
1890	58,351	£16,693	162,561	£89,409	37,591	£7,048	..	..
1899	12,491	£4,424	162,755	£77,309	76,999	£10,625	73,112	£15,010

40,757 tons of limestone valued at £4345 were also raised in 1899. It is impossible to disentangle the figures relating to oil shale from the confusion of the mining inspectors' reports, but the output has certainly fallen off since 1885. In 1891, 50,388 men and 24,391 women were engaged in industrial handicrafts or were dealers in manufactured substances. Of these, 7339 men and 15,992 women were connected with the manufacture of textiles, 5471 men with ships, 5128 men with machines and implements, and 8219 with minerals. Commerce engaged the attention of 10,984 men and 484 women. About 22 miles were added to the railway mileage of the county in the last quarter of the 19th century, and considerable further extensions are now in progress.

MILLAR. *Castles and Mansions of Renfrew.* Glasgow, 1889.—*Harp of Renfrewshire.* Paisley, 1872–73.—P. A. RAMSAY. *View of Renfrewshire.* Edinburgh, 1839. (W. WA.)

Rennes, chief town of department Ille-et-Vilaine, France, and an important railway junction, 232 miles west-south-west of Paris. It is the seat of a Court of Appeal for the five Breton departments. The second trial of Captain Dreyfus took place here. A preparatory school of medicine and pharmacy, in connexion with the university academy, has been reorganized, and there are a national school of agriculture and a school of dairying. A statue of Bastard, former mayor and local benefactor, stands in front of the Chamber of Commerce, a handsome modern structure in the Renaissance style. Population (1881), 47,774; (1896), 57,249.

Renouf, Sir Peter Le Page (1822–1897), Egyptologist, was born in Guernsey, 23rd August 1822. He was educated at Elizabeth College in his native island, and proceeded thence to Oxford, which, upon his becoming a Roman Catholic, under the influence of Dr Newman, he quitted without taking a degree. Like many other Anglican converts, he proved a thorn in the side of the Ultramontane party in the Roman Church, though he did not, like some of them, return to the communion of the Church of England. He opposed the promulgation of the dogma of Papal Infallibility, and his treatise (1868) upon the condemnation of Pope Honorius for heresy by the Council of Constantinople in A.D. 680 had the distinction of being placed upon the index of prohibited books. Previously to this stirring episode in his career he had been from 1855 to 1864 professor of ancient history and Oriental languages in the Roman Catholic university which Newman vainly strove to establish in Dublin, and during part of this period edited the *Atlantis* and the *Home and Foreign Review*, which latter periodical had to be discontinued on account of the hostility of the Roman Catholic hierarchy. In 1864 he was appointed a Government inspector of schools, which position he held until 1886, when his growing celebrity as an Egyptologist procured him the appointment of Keeper of Oriental Antiquities in the British Museum, in succession to Dr Samuel Birch. He was also elected in 1887 president of the Society of Biblical Archæology, to whose *Proceedings* he was a constant contributor. The most important of his numerous and highly valued contributions to Egyptology are his Hibbert lectures on the Religion of the Egyptians, delivered in 1879; and the translation of *The Book of the Dead*, with an ample commentary, which was published in the transactions of the society over which he presided. He retired from the Museum under the superannuation rule in 1891, and died in London on 14th October 1897. He had been knighted the year before his death. He married in 1857 Ludovica von Brentano, member of a well-known German literary family. (R. G.)

Renouvier, Charles Bernard (1818——), French philosopher, was born at Montpellier, 1st January 1818, and educated in Paris at the École Polytechnique. In early life he took much interest in politics, and the approval extended by Hippolyte Carnot to his *Manuel républicain de l'homme et du citoyen* (1848) was the occasion of that minister's fall. He has never held public employment, but has spent his life writing, retired from the world. His chief works are: *Essais de critique générale*, 4 parts (1854–64), *La science de la morale*, 2 vols. (1869), *Uchronie* (1876), *Esquisse d'une classification systématique des doctrines philosophiques*, 2 vols. (1885–86), *La philosophie analytique de l'histoire*, 4 vols. (1896–97), *Histoire et solution des problèmes métaphysiques* (1901). Renouvier has been the first Frenchman since Malebranche to formulate a complete idealistic system, and he has had a vast influence on the development of French thought in the past century. His system is based on Kant's, as his chosen term *Néo-criticisme* indicates; but it is a transformation rather than a continuation of Kantianism. The two leading ideas discernible in it are a dislike to the Unknowable in all its forms, and a reliance on the validity of our personal experience. The former accounts for his decided acceptance of Kant's phenomenalism, combined with an equally decided rejection of the thing in itself. It accounts, too, for his strenuous polemic on the one hand against a Substantial Soul, a Buddhistic Absolute, an Infinite Spiritual Substance; on the other hand against the no less mysterious material or dynamic substratum by which naturalistic Monism explains the world. He holds that nothing exists except presentations, which are not merely sensational, and have an objective aspect no less than a subjective. To explain the formal organization of our experience he adopts a modified version of the Kantian categories. The insistence on the validity of personal experience leads Renouvier to a yet more important divergence from Kant in his treatment of volition. Liberty, he says, in a much wider sense than Kant, is man's fundamental characteristic. Human freedom acts in the phenomenal, not in an imaginary noumenal sphere. Belief is not intellectual merely, but is determined by an act of will affirming what we hold to be morally good. In his religious views Renouvier makes a considerable approximation to Leibnitz. He holds that we are ration-

ally justified in affirming human immortality and the existence of a finite God who is to be a constitutional ruler, but not a despot, over the souls of men. He would, however, regard atheism as preferable to a belief in an infinite Deity.

Rensselaer, formerly known as Greenbush and sometimes as East Albany, a city of Rensselaer county, New York, U.S.A. It is on the Hudson river, opposite Albany, with which it is connected by bridges, and on the New York Central and Hudson River and the Boston and Albany railways. Population (1880), 3295; (1890), 7301; (1900), 7466, of whom 1089 were foreign-born.

Renton, a manufacturing town of Dumbartonshire, Scotland, on the river Leven, 2¼ miles north by west of Dumbarton by rail. It is the centre of the Turkey-red dyeing industry, and calico-printing and bleaching are also carried on. A parish church stands on the site of Dalquhurn House, the birthplace of Tobias Smollett, to whom there is a monument (1775). There is a drill hall and a Jubilee Victoria Institute, with library and recreation rooms. Population (1881), 4319; (1901), 5227.

REPRODUCTION.

IN recent embryological work no idea has been more prominent than that of *germinal continuity*. From one point of view it may be said that multicellular organisms give rise by a process of division to macrogametes or ova, and to microgametes or spermatozoa; that these unite in fertilization to form a new individuality, and that after a period of development this again produces gametes. But, from another point of view, it may be said with equal accuracy that the fertilized ovum gives rise in development to two sets of elements—to the somatic cells which become differentiated into the various tissues of the body, and to a lineage of non-specialized germ-cells, some of which will eventually be separated off to begin a new generation. This lineage of germ-cells is often distinguishable from the somatic cells at an early stage in development, *e.g.*, in some leeches; *Sagitta;* some Nematodes; many Polyzoa; *Moina;* some Cladocera and other Crustaceans; *Chironomus*, *Platygaster*, and some other insects; Phalangidæ among Arachnids, and the Teleostean fish *Micrometrus aggregatus*. Perhaps the most striking instance of early differentiation of germ-cells is that of *Ascaris megalocephala*, described by Boveri (1887, 1891), where from the two-celled stage onwards the germ-cell lineage is distinguishable from the somatic cell lineage by the greater size and richness of the chromatin, and (for a time) by a difference in the process of mitosis. By a process of chromatin elimination, repeated through five or six successive divisions, the somatic cells come to contain a reduced quota of chromatin, while the germ-cells retain the whole amount. More instances of this sort might make it possible to give a precise statement of the relation between germ-cells and somatic cells, but at present only a general contrast is permissible. The somatic cells differentiate in manifold variety, most of them losing all likeness to the fertilized ovum or to its immediate descendants, the blastomeres, though in many cases some retain a power of helping one another to regenerate lost parts or even an entire organism. The germ-cells, on the other hand, are not implicated in building up the body, but remain virtually unchanged, preserving the original organization or "protoplasmic tradition" intact. As the sex-cells in an offspring are thus genetically continuous with the parental sex-cells which gave rise to it, they will in turn develop into organisms like the parents—a conception fundamental to an understanding of inheritance and development. The idea of germinal continuity was expressed by Owen, Haeckel, Rauber, Jaeger, Nussbaum, Brooks, and Galton, but it has been most clearly stated and consistently worked out by Weismann, who has, moreover, adjusted it to meet an obvious difficulty. In many forms, especially among plants, it is only after the differentiation of the body is relatively far advanced that the future reproductive cells are recognizable as such, and thus we have to pass from cases where germ-*cells* form a demonstrable continuous lineage with the fertilized ovum, to the theory of a continuous germ-*plasm*. Weismann assumes that "in each development a portion of the specific germ-plasm, which the parental ovum contains, is not used up in the formation of the offspring, but is reserved unchanged for the formation of the germinal cells of the following generation." This germ-plasm, of definite chemical and special molecular constitution, is supposed to have its seat in the nucleus, and to have great powers of persistence and growth. Part of it is distributed throughout the "body," and may be the material condition of asexual multiplication and regeneration, as well as the determinant of differentiation; but part of it continues with approximately intact stability to form the reproductive cells of the body.

Correlation.—While it may be admitted that the body is the bearer rather than the producer of the germ-cells, it must also be allowed that these cannot lead a charmed life, uninfluenced by somatic accidents and incidents. Vascular and other fluids form a common medium for all parts of the system; the gonads of animals are often under nervous control; alteration of diet may alter reproductivity and even sex; various poisons and the like are known to affect not only the whole bodily system, but the germ-cells as well. Even Weismann, the most prominent upholder of the distinction between soma and germ-cells, finds one of the chief sources of congenital variation in the nutritive stimuli exerted on the germ-plasm by the varying state of the body. On the other hand, many instances are known, if not understood, of correlations between the reproductive system and bodily organs. Thus Rörig (1899) shows that a diseased state of the ovaries in a female deer is correlated with the development of antlers, that atrophy of the testes is always followed by a peculiar growth of antlers, that castration of a young male always inhibits the development of antlers, and so on. Sellheim (1898, 1899) has described some of the numerous somatic changes which follow castration in various animals, one of the most frequent in both sexes being a prolongation of the period of bone-growth. When young cocks are castrated, the whole body is affected; the larynx is intermediate in size between that of cock and hen, the syrinx is weakly developed, the brain and heart are light in weight, fat accumulates in the subcutaneous and subserous connective tissue, and the skeleton shows many abnormalities. From ancient times a correlation between the gonads and the state of various parts of the body—even of the nose—has been recognized in man, and many instances suggest that while the germ-cells are in a sense apart from the general bodily system, an even greater fact is the unity of the organism.

Galton's Law.—Beside the idea of germinal continuity we may rank another generalization of great importance,

namely, Galton's law of ancestral inheritance, based partly on studies in the inheritance of human qualities, and partly on a series of observations on basset hounds. There is a sense in which we may think of an inheritance as dual—half derived from the father and half from the mother—but the heritable material of each parent was also dual, being derived from the grandparents, and Galton's law expresses this conception of inheritance as necessarily multiple. "The two parents between them contribute *on the average* one-half of each inherited faculty, each of them contributing one-quarter of it. The four grandparents contribute between them one-quarter, or each of them one-sixteenth; and so on, the sum of the series $\frac{1}{2}+\frac{1}{4}+\frac{1}{8}+\frac{1}{16}+$ &c., being equal to 1, as it should be. It is a property of this infinite series that each term is equal to the sum of all those that follow: thus $\frac{1}{2}=\frac{1}{4}+\frac{1}{8}+\frac{1}{16}+$ &c.; $\frac{1}{4}=\frac{1}{8}+\frac{1}{16}+$ &c.; and so on. The prepotencies or subpotencies of particular ancestors, in any given pedigree, are eliminated by a law that deals only with *average* contributions; and the varying prepotencies of sex, in respect to different qualities, are also presumably eliminated." It is highly probable, as Karl Pearson says, that the above simple descriptive statement brings into focus all the complex lines of hereditary influence.

Sexual Differentiation.—Numerous facts point to the conclusion that maleness and femaleness may be regarded as expressing metabolic alternatives open to the germ-cell in its development, and that the bias in one direction or the other is largely due to environmental stimuli. In illustration we may recall the very diverse sexual conditions—hermaphrodite, male, female, parthenogenetic, asexual, &c.—observed in the simple multicellular organism *Volvox*, which has been described as furnishing an epitome of the evolution of sex. According to Cuénot, the little starfish *Asterina gibbosa* is in certain localities first male for a variable period, and then female, while in other localities permanent males, females, and hermaphrodites seem to occur. According to W. M. Wheeler's interpretation, *Myzostoma glabrum* has a functional male phase, succeeded by a functional hermaphrodite phase, and that again by a functional female phase during which the testes disappear, while in other species the hermaphrodite period may be almost or wholly suppressed. In plants, in particular, it seems that environmental conditions are often effective in changing a hermaphrodite into a unisexual condition. Very striking both in their results and in the carefulness of method are the experiments of Klebs, which show that environmental changes will determine in various Algæ and Fungi the occurrence of sexual or of asexual reproduction, or will cause a normally hermaphrodite form to become unisexual. It need hardly be pointed out that the view which regards sexual dimorphism as expressing two opposed metabolic diatheses is complementary, not antagonistic, to that which points out how the dimorphism is adaptive to securing cross-fertilization and other advantages.

Oogenesis.—It is convenient to distinguish in the history of both ova and spermatozoa three periods: (*a*) of multiplication, (*b*) of growth, and (*c*) of maturation. During the growth-period in a number of cases there occurs what may be called a struggle for existence among potential germ-cells. Thus among the numerous possible ova in the ovary of *Hydra* there is usually but one survivor, which has grown strong at the expense of its neighbours, and almost the same thing is known in *Tubularia* and in some other cases. Immature ova of sea-urchins have been seen engulfing others, and even spermatozoa (without resulting fertilization), *i.e.*, exhibiting phagocytosis. Many potential ova are often used up to form follicular or other investments for the few which succeed. It may sometimes be that the elimination process, both among young ova and among spermatozoa, is discriminative, *i.e.*, that the survivors survive in virtue of particular fitness; if so, the process may be of racial importance. This extension of the conception of the struggle for existence to the germ-cells may suggest the further extension expressed in Weismann's daring hypothesis of "germinal selection," which supposes the occurrence of an intimate competition among the hereditary units within the germ-cell.

Spermatogenesis.—Recent researches on spermatogenesis have not greatly altered the state of knowledge outlined in the article REPRODUCTION in the ninth edition of the *Encyclopædia Britannica*, but it may be noted that although the parallelism between spermatogenesis and oogenesis suggested in the previous article does not seem to have been accepted, a deeper parallelism has been established (see *infra*); that there is often in the testes of higher animals, as in the ovaries, a division of labour between the germ-cells proper and associated nutritive cells; that the middle piece of the spermatozoon bears a centrosome which plays an important rôle in the division which follows fertilization; that the locomotor tail has often a fibrillated structure which suggests an analogy with a muscle-fibre; that in various Cycads the male nuclei issue from the pollen tube as motile spermatozoa, whose occurrence removes one of the distinctions between flowering plants and Cryptogams; that there is sometimes dimorphism of spermatozoa, *e.g.*, in water-beetles, which suggests another parallel between spermatogenesis and oogenesis (cf. the familiar dimorphism of the ova of Rotifers, &c.).

Reducing Divisions.—Since van Beneden discovered that each of the two nuclei which unite in fertilization contains one-half of the number of chromosomes characteristic of the somatic cells, though the nuclei of the earlier stages of the germ-cells have the same number as the somatic cells, it has been plain that a reducing process must occur at some phase, and there is now general agreement that the reduction takes place in the last two cell-divisions by which the definitive germ-cells arise, namely, when the ovarian ovum gives rise to the mature ovum and two or three polar bodies, and when a spermatocyte divides into four spermatids or young spermatozoa. The parallelism in the two cases is very striking, but as O. Hertwig says, "while in the latter case the products of the division are all used as functional spermatozoa, in the former case one of the products of the egg-mother-cell becomes the egg, appropriating to itself the entire mass of the yolk at the cost of the others, which persist in rudimentary form as polar bodies." The hypothesis of Minot, adopted also by van Beneden, that each germ-cell is originally hermaphrodite, and that the maturation processes imply the removal of male qualities from the ovum and of female qualities from the spermatozoon, has been abandoned; and the reducing divisions are recognized as securing a constancy in the number of chromosomes characteristic of each species, for without some such preliminary reduction the number would obviously be doubled at each fertilization. That a reduction does really occur in both plants and animals seems now incontrovertible, but as to the precise manner of the reduction the results are at present too discrepant to admit of any brief statement. It should be noted, however, that in some parthenogenetic ova, *e.g.*, of Aphides, only one polar body is formed and no reduction in number is effected, while in other parthenogenetic ova, *e.g.*, those eggs of bees which develop into drones, two are formed—a strange fact, in part at least explained by Brauer, who showed that in the parthenogenetic ova of *Artemia* both types occur, but that when two polar bodies are formed the second remains in the egg and behaves practically like a sperm-nucleus.

Fertilization.—Recent work has forcibly suggested that there are in fertilization two more or less distinct processes—on the one hand, the process by which the gametes, bearing the hereditary characters, unite to form the beginning of a new individuality; on the other hand, the process by which the microgamete supplies some stimulus prompting the ovum to divide. The first aspect is that of amphimixis, believed by many to be of importance in initiating—and, it may be, also in checking—variation, but in any case implying the union of the hereditary qualities contained in the two gametes. The second aspect is that of mitotic stimulus, believed by some to be afforded by an enzyme—for which the name of ovulase has been suggested—and by others to be localized in the sperm-centrosome. It is seen in many cases that equivalent numbers of chromosomes are contributed by the two nuclei; it is evident that the ovum contributes by far the larger quantity of cytoplasm; it seems to have been securely demonstrated in some cases that "from the

father comes the stimulus inducing the organization of the machinery of mitotic division by which the egg splits up into the elements of the tissues, and by which each of these elements receives its quota of the common heritage of chromatin." While the ovum centrosome of many animals seems to disappear, that introduced by the spermatozoon divides into two, and around each a system of rays develops. They migrate to opposite sides of the segmentation nucleus, and between them there appears the spindle of the first cleavage. It may be hasty to call them 'kinetic centres,' but they seem to have an important rôle in the division-process. "Huxley hit the mark two score years ago when he compared the organism to a web of which the warp is derived from the female and the woof from the male. Our principal advance upon this view is the knowledge that this web is probably to be sought in the chromatic substance of the nuclei; and perhaps we shall not push the figure too far if we compare the amphiaster to the loom on which the fabric is woven" (Wilson, 1900, p. 231).

The experiments of Maupas on ciliated Infusorians, where an elaborate nuclear reduction is followed by an intimate nuclear amphimixis, seemed to show that conjugation is not effective between the members of an isolated colony all descended by successive fissions from one form, and that after a large number of generations senile degeneracy sets in, and leads to the extinction of the colony unless it be checked in time by the removal of some members to the vicinity of unrelated forms with which they may conjugate. This suggests the view that amphimixis is necessary to sustain the standard of vitality in a stock, but while some believe that there is a primary need for this "rejuvenescence" (a view which is certainly not supported by the entire absence of any amphimixis in forms like Bacteria, nor by persistently parthenogenetic forms, like many Rotifers), others hold that the dimorphism and mutual dependence of the germ-cells is only an elaborate adaptation to secure the origin or multiplication of variations (a view which has found its most thoroughgoing exponent in Weismann). That Maupas's undoubtedly careful work requires confirmation may be inferred from the experiments of Joukowsky (1898), which suggest that degeneracy depends not merely on the number of asexual generations, but on the rapidity of their succession; in *Pleurotricha lanceolata* over 458 generations were observed without the occurrence of degeneracy; after five months' culture a colony of *Paramœcium caudatum* showed no nuclear senility, but only a marked reduction of cilia and consequent sluggishness; in *P. putrinum* effective conjugation between the descendants of one individual was observed, but the author admits the probability that this has its limits.

A remarkable experiment made by Boveri (1889, 1895) cannot be overlooked, though it is still in some respects unsatisfactory, as Seeliger and Morgan have pointed out. Following a method used by the Hertwigs, Boveri subjected Echinoid eggs to shaking, and obtained enucleated fragments. He showed that these were capable of fertilization, and that they gave rise to dwarf larvæ, which were normal except in size and in having only half the usual number of chromosomes in their cells. Boveri went on to fertilize enucleated ovum-fragments of *Sphærechinus granularis* with spermatozoa of *Echinus microtuberculatus*, and obtained in a few cases dwarf larvæ showing purely paternal characteristics. From this he drew the conclusion that it is the nucleus, not the cytoplasm, which forms the material basis of inheritance; and there are many facts, *e.g.*, the history of the chromosomes in maturation, which point in the same direction. It should be borne in mind, however, that as the life of the cell probably depends on the complex interaction of various materials more or less localized in different parts of the unit-area, since the nucleus cannot live for more than a short time without the cytoplasm as its agent, nor the cytoplasm without the nucleus as its trophic or formative centre, it may be misleading to seek too hastily for a definite localization of functions—to attempt, for instance, to abstract the ovum-cytoplasm altogether from any share in bearing the burden of inheritance. In Boveri's experiment it may have been that the hereditary qualities of the sperm proved themselves prepotent over the hereditary qualities of the ovum-cytoplasm, weakened as these might well be by enucleation. In 1899 Delage succeeded in fertilizing non-nucleated fragments of the ova of *Echinus*, *Dentalium*, and *Lanice conchilega*, and reared Pluteus, Veliger, and Trochosphere larvæ respectively. Three larvæ were reared from one ovum of a sea-urchin—from one nucleated and two non-nucleated portions—and in one case a normal blastula was obtained from a $\frac{1}{37}$th ovum-fragment. He showed, moreover, that an egg-fragment of *Echinus* without any chromosomes gave rise after fertilization by a spermatozoon with nine chromosomes to a larva whose cells had the normal number of eighteen chromosomes; which led him to infer that the number of chromosomes is a property of the cellular organization, and not dependent on the persistent individuality believed by most to be characteristic of the chromosomes. The experiments will require confirmation and extension, but unless the cutting operation caused an escape of nucleoplasm into the cytoplasm fragments (which Delage does not believe to have been possible), it is difficult to avoid the conclusion that fertilization may be effective without any fusion of nuclei. In connexion with these remarkable phenomena of "merogonic" fertilization and development, it is perhaps appropriate to recall the observations of Marchal on *Encyrtus fuscicollis*, where the ovum gives rise not to one embryo, but to "a legion of small morulæ," forming a chain of 50–100 embryos. Even more striking, however, are the experiments of Loeb (1899) on the artificial production of normal larvæ (plutei) from the unfertilized eggs of the sea-urchin. He found that this may be effected by placing the unfertilized eggs for about two hours in sea-water to which a dilute solution of magnesium chloride has been added in certain proportions. "When brought back into normal sea-water the eggs began to segment and form blastulæ, gastrulæ, and plutei, which were normal in every respect. The only difference was that fewer eggs developed, and that their development was slower than in the case of the normal development of fertilized eggs." The precise nature of the physical, or chemical and physical, stimulus in this and in other cases of "artificial parthenogenesis" remains uncertain.

Cleavage.—Many hundreds of researches within the last few years have had for their subject the cleavage or segmentation which follows fertilization, but we cannot do more than refer to one general result which seems to be true of most cases of indirect cell-division. The chromatin nuclear material is disposed in a number of segments or chromosomes (whose number is practically constant for each species); each of these chromosomes is split lengthwise during the division process, and the two halves are borne in opposite directions to the two poles, there to form, or to help to form, the daughter-nuclei. As a chromosome is built up of a single series of chromatin-granules, each of which is cleft by the longitudinal splitting, each daughter-nucleus has a contribution from each chromatin-granule. In the movement towards the poles the system of spindle-fibres which radiate from the centrosomes appears to play a part, but whether they push or pull or act in some more subtle way remains uncertain; nor is it known what precise part is played by the astral rays which surround the centrosome but are quite distinct from the spindle-fibres. What is certain is, that the result of the mitotic process is to divide the chromatin substance with exact equality, so that, in the case of a segmenting ovum, each daughter-nucleus is half maternal and half paternal in its composition—a discovery of much interest in connexion with inheritance. Our understanding of the different forms of ovum segmentation advances very slowly, for though some useful "laws" have been stated—*e.g.*, that each new plane of division tends to intersect the preceding plane at right angles (Sachs), or that the axis of the mitotic figure typically lies in the longest axis of the protoplasmic mass, so that the division tends to cut this axis at right angles (Hertwig)—these are only preliminary descriptive formulæ. It is possible that the experiments of Driesch and others, who have observed the cleavage of eggs under the pressure of glass plates, may be of service in enabling us to eliminate the mechanical factors. The associated problem of the relation of the early cleavages to the axes of the future embryo is not less difficult. It is indeed a familiar fact that the ovum may show polar differentiation and bilateral symmetry, and that in some cases, *e.g.*, frog and Tunicate, the first cleavage plane coincides with the median plane of the adult body. On the other hand, the first cleavage sometimes corresponds approximately to the transverse plane of the body (newt); or separates an ectoderm cell from an endoderm cell; or separates a germ-

cell from a somatic cell (*Ascaris*), and so on; so that what it does admits of no general statement. Moreover, the orientation of the ovum may be entirely altered, as in the frog, by artificial conditions, without the normality of the resulting embryo being affected; and a minute ovum-fragment, as in sea-urchins, may give rise to a complete larva; so that there are strong reasons for the view that the egg-cytoplasm is at first isotropous or indifferent, and that its polarity or anisotropy is secondarily acquired, sometimes earlier, sometimes later, and in very varied degrees.

Experimental Embryology.—Particularly significant of recent embryological work has been the frequent recourse to experiment, and within a few years a large literature has grown, with its centre in Roux's *Archiv für Entwicklungsmechanik.* Artificial isolation of blastomeres by cutting or shaking apart; subjection of the developing ova to peculiar conditions of pressure; modifications of temperature, illumination, &c.; and alterations in the chemical character of the medium, have been the four most frequent lines of experiment. The main aim has been to analyse the immediate factors in development, and while it is too soon to estimate the value of the results, some illustrations may be given.

Isolation of Blastomeres.—As long ago as 1869 Haeckel divided the blastulæ or morulæ of Siphonophora with a fine needle into two, three, or four pieces, and observed that each developed into a complete larva. This was one of the first experiments along a line which many investigators followed during the last decade of the 19th century. In 1877 Chun made, though he does not appear to have published, the observation that when the first two blastomeres of a Ctenophore ovum were shaken apart, each formed a half-larva, with four ciliated ridges, four meridional vessels, and one tentacle; moreover, each became sexual, and the half which was wanting was eventually regenerated. The ova of frog, newt, fishes, lancelet, ascidian, mollusc, sea-urchin, medusa, &c., have been made the subjects of similar experiments, in which blastomeres are isolated by shaking the segmenting ovum until separation occurs, or by actually cutting off or puncturing a portion so as to destroy its power of development. By shaking the water in which the two-cell stages of the segmenting ova of *Amphioxus* floated, E. B. Wilson produced from the separated halves two independent twins of half the normal size, each of the isolated cells segmenting like an intact ovum, and giving origin, through blastula and gastrula stages, to a half-sized metameric larva. When incomplete separation was effected by the shaking, double embryos—like Siamese twins—resulted, and formed shortlived segmented larvæ. Complete isolation of the first four blastomeres resulted in four dwarf blastulæ, gastrulæ, and oval larvæ; separation into two pairs of cells yielded two half-sized larvæ; incomplete separation resulted in (*a*) double embryos, (*b*) triple embryos—one twice the size of the others—or (*c*) quadruple embryos, each a quarter size. An isolated blastomere from the eight-cell stage proceeded to segment, but did not reach the gastrula stage.

Numerous experiments on the developing egg of the frog by Roux, Hertwig, Schultze, Morgan, Endres, Walter, Wetzel, and others have after no little controversy made one interesting result clear, that one of the first two blastomeres may develop into a half-embryo, or into a half-sized whole embryo, according to the conditions of the experiment. "So long as the first two blastomeres remain in contact without any disturbance of the cell-contents, each blastomere develops its half of the body. On the other hand, if the protoplasm is disturbed by reversing the position of the egg after the first cleavage, there generally results a whole embryo from each blastomere" (Morgan, 1897, p. 131). Thus we may place the behaviour of the frog's ovum intermediate between that of the Ctenophor (where an isolated blastomere forms a half-embryo) and that of the lancelet (where an isolated blastomere forms a whole embryo of small size).

Pressure Experiments.—By causing a developing ovum (*e.g.*, of frog) to segment between parallel glass plates, or in a glass tube of smaller calibre than the diameter of the egg, this general result has been established, that the distribution of the nuclei may be entirely different from that in normal conditions, and yet normal embryos result. It seems difficult to avoid the conclusion that the sequence of the early nuclear divisions has no necessary relation to the subsequent formation of the embryo, and that the nuclei in these early stages are all equivalent (Morgan, 1897, chap. x.). O. Hertwig (1898) found that when centrifugal force was exerted in a certain degree on the eggs of *Rana esculenta*, it produced a more marked separation of the lighter and heavier substances, in consequence of which the cleavage was restricted to the upper or "animal half" of the ovum. Indeed, a meroblastic type was closely approached, for an undivided yolk-containing portion occupied from one-half to two-thirds of the egg, the remainder was formed by a blastoderm with a blastocoel, and the resemblance was heightened by the formation of a special layer of merocytes—a yolk-syncytium—beneath the blastoderm. But here again, if removed in due time from the disturbing influences, the eggs gave rise to embryos with the normal equipment of organs.

Influence of Temperature.—Numerous experiments have also been made on the influence of temperature on developing ova, but few of the results are at present intelligible. Thus Driesch, prompted by Vejdovsky's note that the eggs of the earthworm, *Allolobophora trapezoides*, most frequently form twin-embryos in warm weather, tried the effect of warming the developing ova of *Sphærechinus granularis*, with the result that in some cases almost all of them formed distinct twin blastulæ, gastrulæ, and even plutei. Similarly, prompted by Selenka's observation that increased temperature produced deviations from the normal cleavage in marine Planarians, Driesch experimented and found that increase of temperature wholly or partially inhibited the formation of the smaller cells or micromeres, and otherwise disturbed the segmentation, without, however, in the end affecting the normality of the result. Again, he found that when the blastulæ of *Sphærechinus granularis*, about twenty-six hours after fertilization, were kept on a stove heated to about 30° C., the great majority showed in about eighteen hours the exogastrula state; *i.e.*, the growing zone at the so-called vegetative pole, which is normally invaginated to form the archenteron, bulged outwards instead of inwards, the final result being shrivelled, gutless, or anenteric larvæ, which survived for a week.

Chemical Reagents.—Another series of studies in experimental embryology is concerned with the influence of chemical reagents upon the developing ova. Thus Curt Herbst has observed the results of placing the eggs of sea-urchins (*Sphærechinus granularis*) in sea-water to which a little lithium chloride has been added, in the proportion of 2·5 cubic centimetres of 3·7 per cent. aqueous solution to 97·5 cubic centimetres of sea-water. In this the fertilized ovum segments into an elongated blastula which becomes constricted into two vesicles, one thick-walled (the archenteric portion), the other thin-walled (the gastrula wall); the thick-walled portion, which should normally be invaginated to form the endoderm, grows out of proportion to what is normally the ectoderm-forming area, and the series ends in a form (holo-entoblastic) in which the thin-walled vesicle or ectodermic area has wholly disappeared. If rather less lithium is used, the type of larva which results is somewhat different, though the two are connected by transitional forms; it is an exogastrula, in which, as the name suggests, the endoderm is evaginate instead of invaginate.

Development.—More clearly than even a dozen years ago we now recognize that the germ-cells, and especially their nuclei, form the material basis of inheritance; that there is genetic continuity between the germ-cells of the parents and those of their offspring; that fertilization implies a union of two individualities condensed for the time being into minute cells; that paternal and maternal characteristics are distributed in exact equality by the nuclear or cellular divisions which constitute the mode of all development; and so on. On the other hand, we have still to confess our entire inability to solve the old problems: How are the specific characters potentially contained within the germ-cells, and by what mechanism do they attain expression in development?

Germinal Areas.—On one view it is supposed that the germ-cell has an architectural organization predetermined before development begins, and that development is in part a "histogenetic sundering" of the pre-existing germinal localization. Some authorities, *e.g.*, Ray Lankester and Whitman, Flemming and van Beneden, have suggested that the predetermination is expressed in the organization of the egg-cytoplasm—the essential idea of the theory of "organogenetic germinal areas" which His elaborated in 1874. This theory may be supported by Roux's experiments on the frog ovum, where, after one of the first two blastomeres had been punctured, the intact half developed into a one-sided embryo; and it may be opposed by Wilson's experiments on the lancelet ovum, where an isolated blastomere of the four-cell stage still formed a complete embryo. It may be supported by the experiments of Morgan and Driesch on Ctenophor ova, where a defect in the cytoplasm is often followed by a modified cleavage and a defective embryo, even when the whole of the nuclear material is intact; and it may be opposed by Delage's experiments on the ova of sea-urchins, &c., where a small (and non-nucleated) fragment of

an egg may be fertilized and give rise to a complete larva. In fact, the experimental results do not as yet settle the question.

Idioplasm.—Supplementary, rather than opposed, to the idea of germinal localization is that of a specific idioplasm, a complex substance which in its molecular organization and in the metabolism which it induces is different for each species. The idea of an idioplasm was first elaborated by Nägeli (1884), who did not concern himself, however, with its particular localization in the germ-cell; this further step was taken by Hertwig, Strasburger, Kölliker, and Weismann, who, from the importance of the nucleus in metabolism, in the regeneration of Protozoon fragments, in maturation, in fertilization, and in cleavage, argued that it—and even more definitely its chromatin—must be the bearer of the idioplasm. On this view the locality of the pre-established organization is shifted from the cytoplasm to the nucleus, though it may still be admitted that in certain cases a cytoplasmic predetermination arises as a secondary result of idioplasmic influence.

Starting from the assumption that the idioplasm of the germ-nuclei was a complex aggregate of different kinds of granules—the material expressions of different sets of qualities—Roux invented the hypothesis of two kinds of nuclear-division, quantitative and qualitative. The former results in equivalent, the latter in dissimilar nuclei; the former is an integral, the latter a differential division. It is the latter mode which is supposed to be characteristic of the early stages of development during which the different components or qualities of the idioplasm are distributed among the blastomeres, each of which, though not independent of its neighbours, is regarded as endowed with a power of "self-differentiation" due to its specific share of the idioplasm.

Similarly, Weismann in his "Germ-Plasm" and elsewhere has elaborated a theory of development which, while confessedly hypothetical, is remarkable in its logical completeness. He supposes the idioplasm or germ-plasm to be built up of numerous different components or "biophores" corresponding to the characteristics of the adult; the biophores are aggregated in groups or "determinants"; the determinants are grouped in "ids"—the chromatin granules; and the "ids" in "idants"—the chromosomes. In the early stages of development there is by differential division a distribution of the components of the germ-plasm. "Ontogeny depends on a gradual process of disintegration of the id of the germ-plasm, which splits into smaller and smaller groups of determinants," till finally only one kind of determinant remains in each cell, there breaking up into its constituent biophores which give the cell its inherited specific character. But while this is going on, there is also a process of quantitative division, which gives rise to the lineage of future germ-cells. The theory of development here outlined has been criticized from many sides. It has often been pointed out that there are no visible phenomena of nuclear division which suggest that the partition may be qualitative; on the contrary, that the whole elaborate process of mitosis seems adapted to secure the equivalence of the two daughter-nuclei. That the division may be differential or qualitative must, of course, be admitted, though we cannot prove it. It is perhaps more to the point to inquire whether the hypothesis fits the known facts, and critics bring forward some of the results of experimental embryology, especially where one of the first two or first four blastomeres is seen to form a normal embryo, or where under artificial conditions (of pressure, &c.) certain cells develop into tissues which in normal conditions are formed by quite different cells. To explain these and other difficulties, *e.g.*, in regenerative phenomena, various ingenious sub-hypotheses have had to be invented.

Without abandoning the position to which almost all modern embryological work has led up, that the essential intrinsic factor in development is the pre-established and inherited organization of the germ-plasm, and without attempting to deny that the nuclear substance may be gradually specialized as differentiation proceeds, it is possible (as Hertwig, Driesch, Morgan, Wilson, and others have shown) to consider the facts of development in a manner somewhat different from that suggested by Roux and Weismann. We may suppose that from the youngest ovarian ovum onwards the nucleus exerts a "control" upon the surrounding cytoplasm, whether by the migration of "pangens" (De Vries, Hertwig), or of specific "formative substances" (Sachs, Loeb), or of enzymes (Driesch), or by a propagation of molecular movements (Nägeli). We may suppose that in some way—varying greatly in degree in different cases—the nucleus prepares in the cytoplasm a framework for its future operations. This may be so slightly pre-established that from a minute fragment of the egg a complete larva may be reared (Echinoid, &c.), or so well established that if a part of the unsegmented egg is removed the remainder forms a defective larva (Ctenophore). When division occurs, the daughter-nuclei, though equivalent, find themselves in a not wholly isotropic medium, and this incites further differentiation, both in the nuclear material and in its cytoplasmic sphere of influence. If the initial cytoplasmic differentiation was slight, the first steps in differentation will be correspondingly slight, and in these cases the isolated blastomeres may still form complete embryos. If the initial cytoplasmic differentiation was more pronounced, the isolated blastomere may not be able to do more than form a partial embryo; the setting of the cytoplasmic mosaic may be too strong to be overcome even by the completely equipped blastomere-nucleus. Thus we reach the idea expressed, for instance, by Driesch: "The relative position of a blastomere in the whole determines in general what develops from it; if its position be changed, it gives rise to something different; in other words, its prospective value is a function of its position." But the "position" is more than merely topographical; it means, as Wilson says, "the physiological relation of the blastomere to the inherited organization of which it formed a part." But even when we recognize the importance of the initial inherited organization, of the influence of segment upon segment as development proceeds, and of the normal environmental stimuli, we have still to confess that the problem of development remains unsolved.

The Recapitulation Doctrine.—The generalization that the individual development or ontogeny of an organism tends to be a recapitulation of the racial evolution or phylogeny is no longer accepted so readily as it was twenty years ago. Many facts have shown that this luminous idea which has certainly guided research may also mislead. Precise embryological investigation has given prominence to the fact—which von Baer himself clearly recognized—that while there is a parallelism between the stages of organogenesis in the individual and the grades exhibited in phylogeny, or in presumed phylogeny, yet there are individual characteristics present from the first. There is a parallelism between the stages of organogenesis in the frog and grades of structure exhibited in fishes, but no one can accurately call the larval frog at any stage piscine; it is an amphibian from first to last. There is a parallelism between the stages in the development of the lens in a higher mammal and grades of lens-structure exhibited in lower Vertebrates, but the rudiment of the lens in the dog is from the first specifically a dog's lens, and nothing else, as Rabl (1899) has shown in detail. In short, the idea of ontogenetic and phylogenetic parallelism must be corrected by the conception that the organism develops as a specific unity.

Regeneration.—Within recent years our knowledge of the occurrence of regeneration and of the internal processes involved has been greatly increased; our understanding of the facts, however, lags far behind. What Réaumur, Lessona, and Darwin suggested, that regeneration is especially characteristic of those organisms and of those parts of organisms which are or have been in the course of nature most liable to breakage or other non-fatal injury, has been especially elaborated by Weismann, who is the chief exponent of the view that regeneration is an adaptive phenomenon, "that the regenerative power of a part is to be considered, not as a direct and necessary expression of the nature of the organism, but rather as a capability which, though it may be absent, is found wherever it is necessary in the interests of species-preservation. The capability of a part for regeneration depends on whether the part was frequently liable to be lost in the ordinary course of life, and also on its relative biological importance for the animal." That internal organs, which are but slightly subject to non-fatal injury, should show little regenerative capacity; that the weak limbs of *Siren* and *Proteus* should not be replaced, though the gills are, and though the strong limbs of *Triton* are; that there should be special regenerative capacity when the leg of an insect is excised at the point where breakage is most apt to occur in the struggles of moulting or ecdysis; that it should be possible to find in the conditions of life some good reason why the beaks of certain birds, *e.g.*, storks, or the eyes of certain animals, *e.g.*, newts, should be readily regenerated; that regeneration should be so common in animals like branching polypes, elongated worms, starfishes, and arthropods;—these are illustrations of the evidence which has led many to regard the occurrence of regeneration as the

adaptive result of natural selection, and not simply as an expression of the primary reproductive capacity of cells. On the other hand, it is pointed out that in some cases there is no definite relation between the regeneration of a part and its liability to injury. Thus, in opposition to Weismann's interpretation, T. H. Morgan has pointed out that the small fourth and fifth thoracic limbs of a hermit-crab, which do not seem to be often (if ever) injured, regenerate readily, that the terminal abdominal appendages, which are entirely protected, likewise regenerate quickly and normally. Or, again, it seems almost impossible that a hermit-crab's walking-leg should under ordinary conditions of life be broken off proximal to the basal "breaking-joint" (between the fifth and sixth segments), where the leg, if injured, is usually thrown off; yet if it be cut off proximal to that joint there is regeneration. Under ordinary circumstances, if a leg is injured distal to the "breaking-joint," the leg is thrown off at the joint; yet regeneration was observed from the cut end of a limb artificially excised outside the breaking-joint. Such facts seem to the observer to show that there is no relation between the regeneration of the leg and its liability to injury. Thus the case for and against the interpretation of regenerative phenomena as adaptive in their occurrence must remain *sub judice* until a large number of instances have been carefully studied. It has also been urged against Weismann's position that the result of regenerative growth is sometimes non-adaptive, as in the instance of a posterior half of an earthworm, observed by Spallanzani (1768), by Morgan (1899), in which the new part was a tail, not a head—the result being a worm with two tails turned in opposite directions. But unless there were many instances of this kind there is no argument, since no one supposes that adaptations are perfect. Two other interesting questions rise out of the study of regeneration: (*a*) How far there is similarity between the regenerative growth and the process of normal development, a question to which opposite answers have been given in different cases and by different observers in the same case; (*b*) how far it is possible at present to form any scientific conception of the manner in which the potentiality of regeneration is distributed and localized within the organism, and kept latent until specific stimuli liberate it. But neither of these questions will at present admit of brief discussion.

Alternation of Generations.—The distinction which Celakowsky introduced in 1868 between two kinds of alternation of generations has been much discussed. Homologous alternation is illustrated by many Algæ and Fungi where offspring of similar appearance are produced in two different ways, either vegetatively or sexually; antithetic alternation is best illustrated by Bryophytes and Pteridophytes where there is a regular alternation between a vegetative sporophyte and a sexual gametophyte which differ entirely in their structure. But there is difference of opinion as to the value of this distinction, or, if it be admitted, as to its applicability to particular cases. Apart from this, it is interesting to note that in many cases the number of chromosomes in the dividing nucleus of the sporophyte is twice that which occurs in the gametophyte. Here too may be noticed the subtle theory of Beard (1896), which suggests that there is a disguised alternation of generations in Vertebrate animals, just as there is in flowering plants. In several Invertebrates, *e.g.*, Echinoderms and *Phoronis*, the egg gives rise to a larva which does not directly develop into the definitive organism, but serves as the foundation on which the development recommences, as it were, on a new tack; similarly Beard maintains that in Vertebrates, whether skate or chick, there are traces of an asexual larval stage, on the top of which the embryo proper develops. At the "critical stage," when the embryo begins to put on its generic and specific characters, it also sets about the task of suppressing the larval foundation.

In-breeding and Crossing.—In regard to close in-breeding there is still much need of experiment, but it seems certain that in many cases with a healthy stock this may go far without disadvantageous results. It seems to fix and strengthen characters, and to develop prepotency—a fact of considerable evolutionary interest, since various forms of isolation may bring about in-breeding in natural conditions. But even when the stock is sound to start with, there seem to be limits to close in-breeding, as von Rath and von Guiata found with rats and mice. As many breeders have recorded, there is a tendency to debility, abnormality, and sterility. According to Reibmayr, the success of a human race is in part dependent on the alternation of periods of sustained in-breeding, in which characters are fixed, and periods of cross-breeding, in which the advantages of "fresh blood" are secured. It is appropriate here to notice that an increased knowledge of the number of cases in which self-pollination or autogamy occurs in plants has led to a somewhat modified statement of the Knight-Darwin conclusion that nature abhors self-fertilization; and the essay of Möbius may be referred to for its vigorous protest against the prevalent idea that continuous vegetative multiplication necessarily results in degeneration.

Hybridization.—Our knowledge of the possibilities of hybridization in artificial conditions and of its actual occurrence in nature is slowly increasing, but few general statements can as yet be ventured. That it occurs readily in some cases, and is rarely successful in others, is well known, but the reasons for this appear to be manifold. One of the results of Pflüger's extensive experiments on the hybridizing of Amphibians points to the importance of what may be called the mechanical factors; thus the spermatozoa of *Rana fusca*, which have very pointed heads, thinner than those of related forms, can fertilize the eggs of nearly all other species (*R. arvalis*, *R. esculenta*, and *Bufo communis*), but the blunt, thick-headed spermatozoa of *R. arvalis* and *R. esculenta* cannot fertilize the eggs of any other species. On the other hand, Hertwig's experiments on sea-urchins suggest that the possibility of crossing depends in great part on the state of the egg; thus eggs in good condition resist the entrance of foreign spermatozoa to which stale eggs prove receptive. It has also been made clear that segmentation may occur after hybridization without further development succeeding; thus T. H. Morgan fertilized the ova of a starfish with the spermatozoa of a sea-urchin, and reared hybrid gastrulæ, but no further stages. While a general result of hybridization is to induce variation, *i.e.*, to alter the normal expression of inheritance, the results seem extraordinarily diverse and unpredictable, the offspring sometimes resembling the male parent, sometimes the female, sometimes neither. In some cases the result is novel, in other cases there seems to be a return to the characters of an ancestral form. In the latter case it may be that latent characters which have for a time been unexpressed are suddenly permitted to develop, or that a new permutation of hereditary qualities independently reproduces an old pattern. Ewart paired a pure white fantail cock-pigeon with a cross previously made between an owl and an archangel pigeon, and the result was a couple of which one resembled the Shetland rock-pigeon, and the other the blue rock of India; von Guiaita found that if the Japanese dancing mouse was crossed with an albino, the second generation consisted of grey mice like the wild forms. Standfuss has suggested that in crossing butter-

flies the phylogenetically older species is prepotent over the younger; Vernon has shown that in sea-urchins the characters of the hybrid offspring incline to be those of the species whose elements were relatively the more mature when fertilization occurred. In short, the variable results seem to be such as might ensue from a germinal struggle between hereditary characteristics of varying strength. Suchetet has recorded 82 cases of what he believes to be genuine species-hybridism in mammals, and 178 in birds: of the 82 crosses between mammals of different species, 62 resulted in sterile offspring; of the 178 crosses between distinct species of birds, only 22 have been known to result in fertile offspring. As to the causes of the sterility little is as yet known, but Suchetet speaks of cases where the gonads were atrophied and of others where the ducts were abnormal.

Telegony.—The ancient and still widespread belief that offspring may resemble not so much, or not only, their parents or ancestors, but a previous mate of their mother, has been much discussed during recent years. Ewart (1899) has experimented especially with horse and zebra, and has not in any case found satisfactory evidence of telegony. Moreover, he has pointed out that the reversions which not infrequently follow the crossing of different breeds may have supplied the material on which the belief in telegony has grown. Other critics have for the most part been content to point out the inherent difficulties in any theory of the mechanism of telegony, whether on the infection-hypothesis (according to which the sperm of the previous sire exerts an influence upon the bodily constitution or gonads of the mother) or on the saturation-hypothesis (according to which an influence from the unborn offspring of the first crossing is supposed to affect the body or gonads of the mother in a manner so specific that offspring by a second sire may present resemblance to the first, with which they are in no way genetically related). At present the scientific evidence is so distinctly unfavourable to belief in the occurrence of telegony, that to discuss suggested explanations or criticisms seems unnecessary.

(J. A. T.)

Reptiles, as known in the existing world, are the modified, and in many respects degenerate, representatives of a group of vertebrate animals which attained its maximum development in the Mesozoic period. So far as can be judged from the skeleton, some of the members of this group then living might have become mammals by very slight change, while others might as readily have evolved into birds. It is therefore probable that the class Reptilia, as now understood, comprises the direct ancestors both of the Mammalia and Aves. Assuming that its extinct members, which are known only by skeletons, were organized essentially like its existing representatives, the class ranks higher than that of the lowest five-toed vertebrates (class Amphibia) in the investment of the fœtus by two membranous envelopes (the amnion and allantois), and in the total absence of gills even in the earliest embryos. It ranks below both the Mammalia and Aves in the partial mixture of the arterial blood with the venous blood as it leaves the heart, thus causing the organism to be cold-blooded; it also differs both from Mammalia and Aves in retaining a pair of aortic arches, of which only the left remains in the former, while the right one is retained in the latter. No feature in the endoskeleton is absolutely distinctive, except possibly the degeneration of the parasphenoid bone, which separates the Reptilia from the Amphibia. In the exoskeleton, however, the epidermis forms horny scales, such as never occur in Amphibia, while there are no traces of any structures resembling either hairs or feathers, which respectively characterize Mammalia and Aves.

There is little doubt that true reptiles date back to the latter part of the Palæozoic period, but at that epoch the Amphibia approached them so closely in the characters of the skeleton that it is difficult to distinguish the members of the two classes among the fossils. Some of the Palæozoic Amphibia—a few of the so-called Labyrinthodonts—are proved to have had well-developed gill-arches in their immature state, while there are conspicuous marks of slime-canals on their skulls. Others are merely regarded as Amphibia because they closely resemble the genera which are proved to have been gill-breathers when immature. All these genera, however, so far as known, agree with the existing Amphibia in the production of their large parasphenoid bone as far forwards as the vomers to form a rigid and complete basicranial axis (Fig. 1, A). Those genera which less resemble the typical Labyrinthodonts are characterized by the reduction of the parasphenoid bone so that it no longer reaches the vomers; in these animals the weakened skull exhibits a secondary basicranial axis formed by the approximation of the pterygoids to the median line (Fig. 1, B). The latter condition is universal in existing reptiles, and may therefore perhaps be regarded as a diagnostic feature. If so, the oldest known undoubted reptile is *Palæohatteria,* from the Lower Permian of Saxony.

In the structure of the skull *Palæohatteria* is much like the existing *Sphenodon,* the cheek-plates which cover the temporal and masseter muscles on each side being pierced by two great vacuities, one superior-temporal, the other lateral-temporal. The majority of the earliest reptiles, however, either resemble the Labyrinthodonts in having the biting muscles completely covered with a roof of bony plates, or exhibit a slight shrinkage of this investment so that a superior-temporal vacuity appears. As the various groups or orders become differentiated, this shrinkage or reduction continues, while the shape of the ossifying ear-capsule changes, and the squamosal

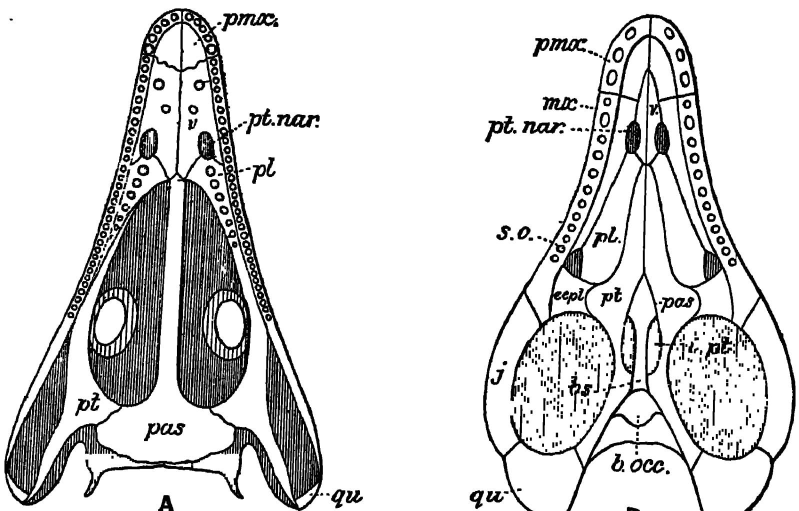

Fig. 1.—A, Palate of Palæozoic Amphibian (*Archegosaurus decheni*). (*After Credner.*) B, Palate of Mesozoic Reptile (*Plesiosaurus macrocephalus*). (*After C. W. Andrews.*) *b.occ*, basioccipital; *bs*, basisphenoid; *ecpt*, ectopterygoid; *i.pt*, interpterygoid vacuity; *j*, jugal; *mx*, maxilla; *pas*, parasphenoid; *pl*, palatine; *pmx*, premaxilla; *pt*, pterygoid; *pt. nar*, posterior nares; *qu*, quadrate; *s.o*, suborbital vacuity; *v*, vomer.

bone, which covers the organ of hearing in the fishes, and presumably also in the Palæozoic Amphibia, is gradually thrust outwards from all connexion with this capsule except at its hinder angle. The resultant modifications are diagrammatically represented in Fig. 2. In one series of orders, comprising the Anomodontia, Chelonia, Sauropterygia, and Ichthyopterygia (Fig. 2, B, C), the superior-temporal vacuity (*s*) first appears; and the cheek-plates in the broad temporal arch thus formed may be variously fused together, sometimes even irregularly perforated—showing at first, indeed, the usual inconstancy of a new and not completely established feature. From the earliest members of this series of reptiles, palæontology seems to demonstrate that the Mammalia (with one robust temporal arcade or zygomatic arch) arose. In a second series, comprising the orders Rhynchocephalia, Dinosauria, Crocodilia, and Ornithosauria (Fig. 2, D), the broad arch of cheek-plates is regularly pierced by a lateral-temporal vacuity, which leaves a narrow bar above, another narrow bar below, and uncovers the middle part of the quadrate bone. By the constant loss of the lower, and the frequent loss of the upper, bar, some members of this series eventually pass into the order Squamata (Lacertilia + Ophidia), in which the quadrate

B, Generalized Anomodont or Sauropterygian, passing with slight modification into the Chelonian (sutures dotted to denote inconstancy in fusion of elements). C, *Ichthyosaurus*. D, Generalized Rhynchocephalian, Dinosaurian, Crocodilian, or Ornithosaurian. E, Generalized Lacertilian, often losing even the arcade here indicated. F, Generalized bird. *fr*, frontal; *j*, jugal; *l*, lateral temporal vacuity; *la*, lachrymal; *mx*, maxilla; *n*, narial opening; *na*, nasal; *o*, orbit; *pa*, parietal; *pmx*, premaxilla; *prf*, prefrontal; *ptf*, postfrontal; *pto*, postorbital; *q.j*, quadrato-jugal; *qu*, quadrate; *s*, supratemporal vacuity; *s.t*, supratemporals and prosquamosal; *sq*, squamosal. Vacuities shaded with vertical lines, cartilage bones dotted. (*From A. S. Woodward, "Outlines of Vertebrate Palæontology."*)

bone is completely exposed and loosely attached to the skull (Fig. 2, E); other reptiles exhibiting a similar modification may readily have acquired the typical Avian skull (Fig. 2, F) by the loss of the upper and the retention of the lower temporal bar in question.

In view of these and other palæontological considerations, the Reptilia may be classified into orders as follows:—

ORDERS OF CLASS REPTILIA.

1. **Anomodontia.**—Bones of postero-lateral region of skull forming a complete roof over the temporal and masseter muscles, or contracted into a single broad zygomatic arch, leaving a superior-temporal vacuity. Pineal foramen present. Ribs double-headed. No abdominal ribs. A large separately ossified epicoracoid. Limbs for support as well as progression; third and fourth digits with not more than three phalanges. Dermal armour feeble or absent. *Range.*—Permian and Triassic.

2. **Chelonia.**—Postero-lateral region of skull as in Anomodontia, except bones of ear-capsule more modified. No pineal foramen. Ribs single-headed. No sternum. Pectoral and pelvic arches unique in being situated completely inside the ribs. No epicoracoid. Abdominal ribs replaced by three or four pairs of large plates, which, with the clavicles and interclavicle, form a plastron. Limbs only for progression; some of the long bones with separately ossified epiphyses; third and fourth digits with not more than three phalanges. A regular dorsal carapace of bony plates intimately connected with the neural spines, and ribs of seven to nine dorsal vertebræ. *Range.*—Upper Triassic to Recent.

3. **Sauropterygia.**—Bones of postero-lateral region of skull contracted into a single broad zygomatic arch, leaving a superior-temporal vacuity. Pineal foramen present. No fused sacral vertebræ. All dorsal ribs single-headed, articulating with transverse processes of the neural arches. Abdominal ribs forming dense plastron. Apparently no sternum. Coracoid, pubis, and ischium in form of much expanded plates. Humerus and femur with separately ossified conical epiphyses. Limbs modified as paddles, with not more than five digits, of which the third and fourth always have more than three phalanges; all digits usually consisting of numerous phalanges. No dermal armour. *Range.*—Upper Triassic to Cretaceous.

4. **Ichthyopterygia.**—Bones of postero-lateral region of skull contracted into a single broad zygomatic arch, leaving a superior-temporal vacuity. Pineal foramen present. Vertebral centra short and deeply biconcave, with feeble neural arches which are almost or completely destitute of zygapophyses. No fused sacral vertebræ. Cervical and dorsal ribs double-headed, articulating with tubercles on the vertebral centra. Abdominal ribs forming dense plastron. Apparently no sternum. Coracoid an expanded plate, probably with cartilaginous epicoracoid. Pelvis very small, not connected with vertebræ. Limbs modified as paddles, with digits of very numerous short phalanges, which are closely pressed together, sometimes with supplementary rows of similar ossicles. No dermal armour. A vertical triangular caudal fin, not supported by skeletal rays. *Range.*—Upper Triassic to Cretaceous.

5. **Rhynchocephalia.**—Bones of postero-lateral region of skull contracted into two slender zygomatic bars, leaving a superior-temporal and a lateral-temporal vacuity, and partly exposing the quadrate bone from the side. Pineal foramen present or absent. Ribs single-headed. Abdominal ribs present. Sternum present. Epicoracoid cartilaginous. Limbs only for progression; third and fourth digits with four or five phalanges. Dermal armour feeble or absent. *Range.*—Lower Permian to Recent.

6. **Dinosauria.**—Postero-lateral region of skull as in Rhynchocephalia. No pineal foramen. Cervical and dorsal ribs double-headed. No abdominal ribs. Sternum present, but apparently no clavicular arch. Limbs for support as well as progression; third and fourth digits with four and five phalanges respectively. Dermal armour variable. *Range.*—Triassic to Cretaceous.

7. **Crocodilia.**—Postero-lateral region of skull as in Rhynchocephalia. No pineal foramen. Cervical and dorsal ribs double-headed. Abdominal ribs present. Sternum present; also interclavicle, but no clavicles. Limbs only for progression on land or swimming; third and fourth digits with four or five phalanges. Dermal armour variable. *Range.*—Lower Jurassic to Recent.

8. **Ornithosauria.**—All bones extremely dense, light, and hollow, the organism being adapted for flight. Postero-lateral region of skull as in Rhynchocephalia. No pineal foramen. Cervical and dorsal ribs double-headed. Abdominal ribs present. Sternum present, and keeled for attachment of pectoral muscles; no clavicular arch. Fifth digit of hand much elongated to support a wing-membrane, but with only four phalanges. Hind limb feeble. No dermal armour. *Range.*—Lower Jurassic to Cretaceous.

9. **Squamata.**—Bones of postero-lateral region of skull much reduced and partly wanting, never forming more than a slender superior-temporal bar, thus completely exposing the quadrate, which is only loosely attached to the cranium at its upper end. Pineal foramen present. Ribs single-headed. No abdominal ribs. Sternum present when there are limbs. Limbs, when present, only for progression; third and fourth digits at least with more than three phalanges. Dermal armour feeble or absent. *Range.*—Cretaceous to Recent.

Order 1. ANOMODONTIA.—The Anomodonts are so named in allusion to the peculiar and unique dentition of the first-discovered genera. They are precisely intermediate between the Labyrinthodont Amphibia and the lowest or Monotreme Mammalia. They flourished at the period when the former are known to have reached their culmination, and when the latter almost certainly began to appear. Many of them would, indeed, be regarded as primitive Mammalia, if they did not retain a pineal foramen, a free quadrate bone, and a complex mandible. The term *Theromorpha* or *Theromora* is thus sometimes applied to the Order they represent. So far as known, they are all land-reptiles, with limbs adapted for habitual support of the body, and their feet are essentially identical with those of primitive mammals. Most of them are small, and none attain a gigantic size. They first appear in the Permian of Europe and North America, and also occur in the Triassic both of Europe and India, but they are best represented in the Karoo formation (Permian and Triassic) of South Africa. The *Pariasauria* most closely resemble the Labyrinthodont Amphibia, but have a single occipital condyle. One genus (*Otocœlus*) has a carapace suggesting that it may be an ancestral Chelonian. The *Theriodontia* exhibit the marginal teeth differentiated

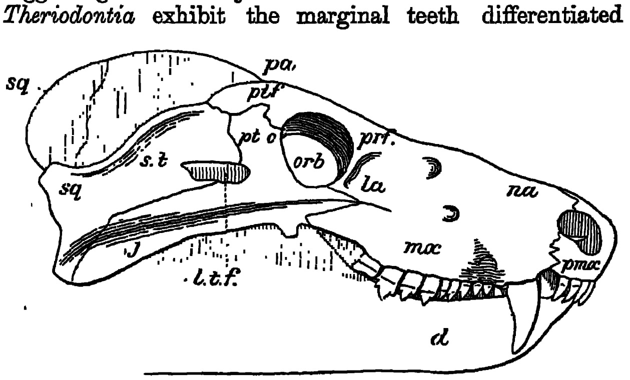

FIG. 3.—Skull of an Anomodont (Theriodont) Reptile (*Cynognathus crateronotus*), one-fifth nat. size.—Karoo formation (Permian or Triassic), South Africa. *d*, dentary; *j*, jugal; *l.t.f*, incipient lateral temporal vacuity; *la*, lachrymal; *mx*, maxilla; *na*, nasal; *orb*, orbit; *pa*, parietal; *pmx*, premaxilla; *prf*, prefrontal; *pt.o*, postorbital; *ptf*, postfrontal; *s.t*, supratemporal (prosquamosal); *sq*, squamosal. (*From A. S. Woodward, "Outlines of Vertebrate Palæontology."*)

(in shape) into incisors, canines, and molars (Fig. 3). They have two occipital condyles, as in mammals. The *Dicynodontia* have one pair of upper tusks or are toothless: their occipital condyle is trefoil-shaped, as in Chelonia.

Order 2. CHELONIA.—This Order occurs first in the Upper Triassic of Würtemberg, where a complete "shell" has been found (*Proganochelys*). They are proved to have been toothless since the Jurassic period, and have only changed very slightly since their first appearance. The marine turtles seem to have first acquired elongated paddles and vacuities in the shell during the Cretaceous period, and the Trionychia, destitute of epidermal shields, apparently arose at the same time.

Order 3. SAUROPTERYGIA.—These are amphibious or aquatic reptiles (Fig. 4). The head is comparatively small in most genera, and the neck is usually elongated though not flexible. The tail is insignificant, generally short, and both pairs of paddles seem to have been concerned in progression. The Order appears to have arisen from a group of land-reptiles, for its earliest members, from the Triassic of Europe (*Lariosaurus*), South

Africa (*Mesosaurus*), and Brazil (*Stereosternum*), are all amphibious animals. They are comparatively small, and their limbs are only just becoming paddle-like. The skull suggests affinities with the terrestrial Anomodontia, and the shape of the scapula and the epiphyses of the humerus and femur seem to show some connexion with the Chelonia. The truly aquatic Sauropterygians of the Jurassic (Fig. 4) and Cretaceous periods possess most effective paddles with elongated digits, and as the genera are traced upwards in the geological formations it is possible to observe how the arches supporting the limbs become more rigid until the maximum of strength is reached. Some of the largest Upper Jurassic and Cretaceous species must have been 10 metres in length. They were cosmopolitan in their distribution, but became extinct before the dawn of the Tertiary period.

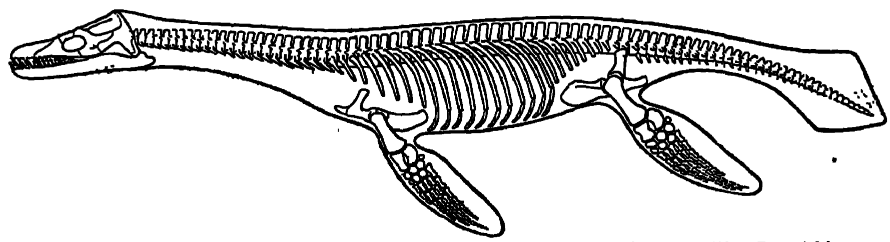

FIG. 4.—*Plesiosaurus rostratus*: restoration of skeleton by W. G. Ridewood.—Lower Lias, Dorsetshire.

Order 4. ICHTHYOPTERYGIA.—The Ichthyosaurians are all fish-shaped, with a relatively large head and very short neck. Both pairs of paddles are retained, but the hinder pair is usually very small, and locomotion seems to have been chiefly effected by a large caudal fin. This fin, as shown in impression by certain fossils from Würtemberg and Bavaria, is a vertical, triangular, dermal expansion, without any skeletal support except the hindermost part of the attenuated vertebral column, which extends along the border of its lower lobe (Fig 5). Another triangular fin, without skeletal support, is known to occur on the back, at least in one species (Fig. 5). Some of the genera are proved to have been viviparous. Like the Sauropterygia, the Ichthyopterygia appear to have originated from terrestrial ancestors, for their earliest Triassic representatives (*Mixosaurus*) have the teeth less uniform and the limbs slightly less paddle-shaped than the later genera. In this connexion it is noteworthy that their hollow conical teeth exhibit curious infoldings of the wall, like those observed in many Labyrinthodonts, while their short, biconcave vertebræ almost exactly resemble those of the Labyrinthodont *Mastodonsaurus* and its allies. As the Ichthyosaurs are traced upwards in geological time, some genera become almost, or quite, toothless (*Baptanodon*), while the paddles grow wider, and are rendered more flexible by the persistence of cartilage round their constituent bones (*Ophthalmosaurus*). They were cosmopolitan in distribution, but disappeared from all seas at the close of the Cretaceous period. The largest forms, with a skull 2 metres in length, occur in the Lower Lias.

Order 5. RHYNCHOCEPHALIA.—These are small lizard-shaped reptiles, which have scarcely changed since the Triassic period. Though now represented only by *Sphenodon* or *Hatteria*, which survives in certain islands off New Zealand, in the Mesozoic epoch they ranged at least over Europe, Asia, and North America. They comprise the earliest known reptile, *Palæohatteria*, from the Lower Permian of Saxony, which differs from the Triassic and

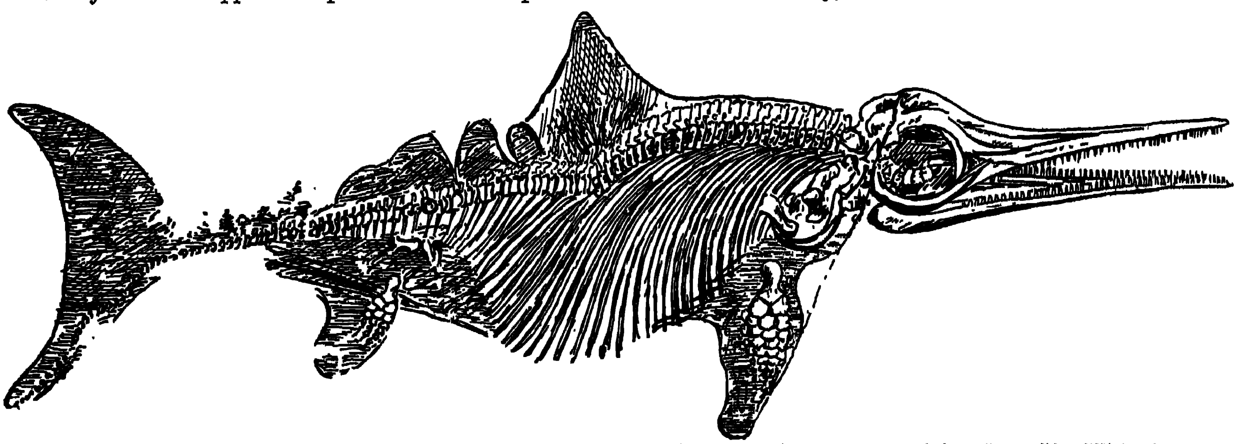

FIG. 5.—*Ichthyosaurus quadriscissus*: outline of specimen showing dorsal and caudal fins, about one-sixth natural size.—Upper Lias, Würtemberg. (*After E. Fraas.*) The irregularities behind the triangular dorsal fin are torn pieces of skin.

later genera in having an imperfectly ossified pubis and ischium, more numerous abdominal ribs, and the fifth metatarsal bone normal. They also seem to include various Triassic genera (e.g., *Aetosaurus*, *Belodon*), which may perhaps belong to the ancestral stock of the Dinosauria and Crocodilia. Other Triassic genera (*Hyperodapedon*, *Rhynchosaurus*) scarcely differ from *Sphenodon*, except in the dentition. In the late Cretaceous and early Eocene periods one genus (*Champsosaurus*) was truly aquatic, with gavial-shaped head.

Order 6. DINOSAURIA. — The Dinosaurs are land-reptiles which flourished on all the continents during the Jurassic and Cretaceous periods, in the interval between the decline of the Anomodontia and the dominance of the Mammalia. They first appeared as carnivorous reptiles in the Triassic period in Europe, India, South Africa, and North America, but afterwards also comprised numerous massive herbivores in nearly all parts of the world except the Australian and New Zealand regions. Among the latter are the largest known land animals of any age: *Brontosaurus*, from the Jurassic of Wyoming, measures at least 17 metres in length, and the femur of *Atlantosaurus*, from the Jurassic of Colorado, indicates a still larger animal. The species of some genera (e.g., *Iguanodon*, Fig. 6) appear to have had a bipedal gait, with the pelvis and hind limbs much like those of the struthious birds. The bones of some are also hollow, thin-walled, and dense, with perfectly ossified articulations. It has therefore been suggested that certain arboreal Dinosaurs were the ancestors of the class Aves. Those genera which comprise species evidently quadrupedal in gait exhibit a very different and typically reptilian pelvis, and are often

heavily armoured. Some of the latest Cretaceous forms from North America bear large horns on the head (e.g., *Triceratops*, Fig. 7).

Order 7. CROCODILIA.—Typical crocodiles can be traced downwards to the Lower Lias at the base of the Jurassic formations, but all the Jurassic and some of the Cretaceous genera have the secondary bony palate less extended backwards than that in the Tertiary and existing genera, while their vertebræ have flattened or concave ends, instead of exhibiting a ball-and-socket articulation. Some of the Upper Jurassic crocodiles (*Metriorhynchus*) were more truly aquatic than any now living, with the fore limbs degenerate, the hind limbs much enlarged for swimming, and the dermal armour lacking. Typical crocodiles and alligators date back to the close of the Cretaceous period, and they did not become extinct in Europe until the beginning of the Miocene period. Remains of an extinct alligator (*Diplocynodon*) are common in the Upper Eocene sands of the Hordwell cliffs, Hampshire.

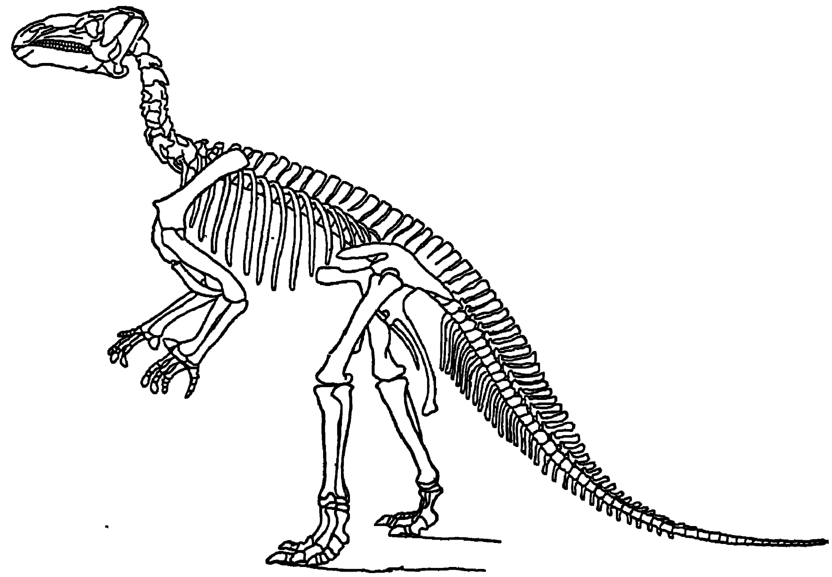

FIG. 6.—*Iguanodon Bernissartensis*: restoration of skeleton by O. C. Marsh, one-eightieth natural size.—Wealden, Bernissart, Belgium.

Order 8. ORNITHOSAURIA.—The flying reptiles are completely evolved at their earliest known appearance in the Lower Lias (*Dimorphodon*), and exhibit little essential change as they are traced upwards through the Mesozoic formations. The latest Cretaceous genera, however, comprise the largest species, which have been found in Europe, North America, and Brazil. Some of these (*Pteranodon*) are toothless, and their wings are so large that for adequate support the pectoral arch is fixed to the vertebræ like a pelvis. The wing-membranes are only known in the European Jurassic genus, *Rhamphorhynchus* (Fig. 8), found well preserved in the fine-grained lithographic stone of Bavaria.

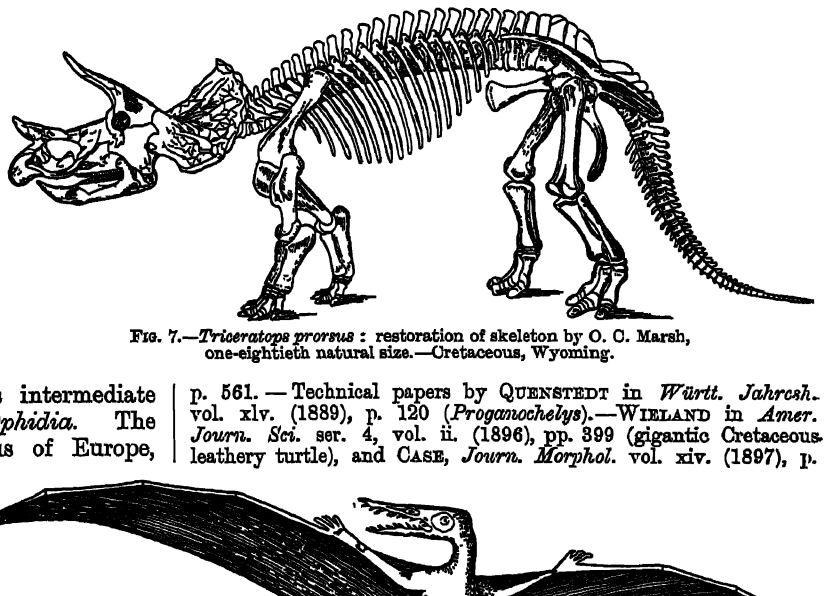

FIG. 7.—*Triceratops prorsus*: restoration of skeleton by O. C. Marsh, one-eightieth natural size.—Cretaceous, Wyoming.

Order 9. SQUAMATA.—The ancestors of the lizards and snakes can only be traced back definitely to the latter part of the Cretaceous period. They were then represented by two suborders of aquatic reptiles, the *Dolichosauria* and *Pythonomorpha* (or *Mosasauria*), which are in many respects intermediate between the existing *Lacertilia* and *Ophidia*. The *Dolichosauria*, from the Upper Cretaceous of Europe, are small and snake-like in shape, but with completely formed limbs. The *Pythonomorpha* are known from Europe, North and South America, and New Zealand, and sometimes attained a very large size, the typical *Mosasaurus camperi* from Maastricht being about 15 metres in length. Their limbs are powerful paddles. The *Lacertilia* and *Ophidia*, so far as known, are exclusively Tertiary and Recent reptiles. Marine snakes (*Palæophis*) occur in the Eocene of the London and Hampshire basins.

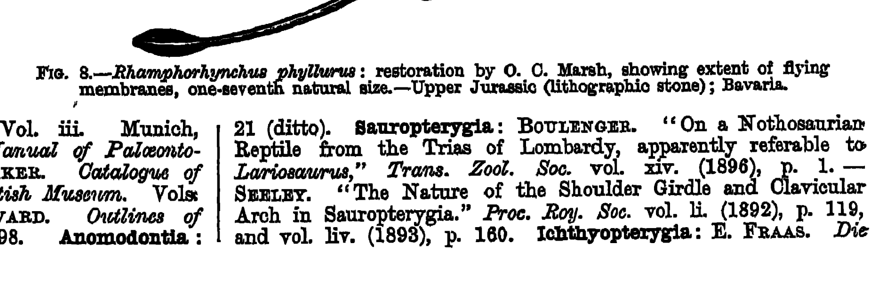

FIG. 8.—*Rhamphorhynchus phyllurus*: restoration by O. C. Marsh, showing extent of flying membranes, one-seventh natural size.—Upper Jurassic (lithographic stone); Bavaria.

Requena, a town of Spain, province of Valencia, on the left bank of the river Magro, with a station on the railway from Valencia to Utiel. Population (1877), 13,527; (1897), 14,495. The town is irregularly built, with only a few good-looking streets, a modern theatre and town-hall, and two squares. There are three parish churches, San Nicolas being the oldest, of the 13th century, partly restored in 1727. Near the town are the sulphurous springs of Fuentepodrida.

Reservation of the Eucharist. — The practice of reserving the sacred elements for the purpose of subsequent reception prevailed in the Church from very early times. The Eucharist being the seal of Christian fellowship, it was a natural custom to send portions of the consecrated elements by the hands of the deacons to those who were not present (Justin Martyr, *Apol.* i. 65). From this it was an easy development, which prevailed before the end of the 2nd century, for churches to send the consecrated Bread to one another as a sign of communion (the so-called Eulogiæ mentioned by Irenæus, *ap.* Eus. *H. E.* v. 24), and for the faithful to take it to their own homes and reserve it in *arcæ* or caskets for the purpose of communicating themselves (Tert. *ad Uxor.* ii. 5, *de Orat.* 19; St Cypr. *de Lapsis*, 132). Being open to objection on grounds both of superstition and of irreverence, these customs were gradually put down by Councils of the 4th and 5th centuries. But some irregular forms of reservation still continued: the prohibition as regards the lay people was not extended, at any rate with any strictness, to the clergy and monks; the Eucharist was still carried on journeys; occasionally it was buried with the dead, and in a few cases the pen was even dipped in the chalice in subscribing important writings. Meanwhile, both in East and West, the general practice has continued unbroken of reserving the Eucharist, in order that the "mass of the presanctified" might take place on certain "aliturgic" days, that the faithful might be able to communicate when there was no celebration, and above all that it might be at hand to meet the needs of the sick and dying. It was reserved in a closed vessel, which took various forms from time to time, known in the East as the ἀρτοφόριον, and in the West as the *turris*, the *capsa*, and later on as the *pyx*. In the East it was kept against the wall behind the altar; in the West, in a locked aumbry in some part of the church, or (as in England and France) in a pyx made in the form of a dove and suspended over the altar.

In the West it has been used in other ways. A portion of the consecrated Bread from one Eucharist, known as the "Fermentum," was long made use of in the next, or sent by the bishop to the various churches of his city, no doubt with the object of emphasizing the solidarity and the continuity of "the one Eucharist"; and amongst other customs which prevailed for some centuries, from the 8th onward, were those of giving it to the newly ordained in order that they might communicate themselves, and of burying it in or under the altar-slab of a newly consecrated church. At a later date, apparently early in the 14th century, began the practice of carrying the Eucharist in procession in a monstrance; and at a still later period, apparently after the middle of the 16th century, the practice of Benediction with the reserved sacrament, and that of the "forty hours' exposition," were introduced in the churches of the Roman communion. It should be said, however, that most of these practices met with very considerable opposition both from Councils and from theologians and canonists, amongst others from the English canonist William Lyndwood (*Provinciale*, lib. iii. c. 26), on the following grounds amongst others: that the Body of Christ is the food of the soul, that it ought not to be reserved except for the benefit of the sick, and that it ought not to be applied to any other use than that for which it was instituted.

In England, during the religious changes of the 16th century, such of these customs as had already taken root were abolished; and with them the practice of reserving the Eucharist in the churches appears to have died out too. The general feeling on the subject is expressed by the language of the 28th Article, first drafted in 1553, to the effect that "the sacrament of the Lord's Supper was not by Christ's ordinance reserved, carried about, lifted up, or worshipped," and by the fact that a form was provided for the celebration of the Holy Eucharist for the sick in their own homes. This latter practice was in accordance with abundant precedent, but had become very infrequent, if not obsolete, for many years before the Reformation. The first Prayer-Book of Edward VI. provided that if there was a celebration in church on the day on which a sick person was to receive the Holy Communion, it should be reserved, and conveyed to the sick man's house to be administered to him; if not, the curate was to visit the sick person before noon and there celebrate according to a form which is given in the book. At the revision of the Prayer-Book in 1552 all mention of reservation is omitted, and the rubric directs that the communion is to be celebrated in the sick person's house, according to a new form; and this service has continued, with certain minor changes, down to the present day. That the tendency of opinion in the English Church during the period of the Reformation was against reservation is beyond doubt, and that the practice actually died out would seem to be equally clear. The whole argument of some of the controversial writings of the time, such as Bishop Cooper on *Private Mass*, depends upon that fact; and when Cardinal du Perron alleged against the English Church the lack of the reserved Eucharist, Bishop Andrewes replied, not that the fact was otherwise, but that reservation was unnecessary

in view of the English form for the Communion of the Sick: "So that reservation needeth not; the intent is had without it" (*Answers to Cardinal Perron, &c.*, p. 19, Library of Anglo-Catholic Theology). It does not follow, however, that a custom which has ceased to exist is of necessity forbidden, nor even that what was rejected by the authorities of the English Church in the 16th century is so explicitly forbidden as to be unlawful under its existing system; and not a few facts have to be taken into account in any investigation of the question. (1) The view has been held that in the Eucharist the elements are only consecrated as regards the particular purpose of reception in the service itself, and that consequently what remains unconsumed may be put to common uses. If this view were held (and it has more than once made its appearance in Church history, though it has never prevailed), reservation might be open to objection on theological grounds. But such is not the view of the Church of England in her doctrinal standards, and there is an express rubric directing that any that remains of that which was consecrated is not to be carried out of the church, but reverently consumed. There can therefore be no theological obstacle to reservation in the English Church: it is a question of practice only. (2) Nor can it be said that the rubric just referred to is in itself a condemnation of reservation: it is rather directed, as its history proves, against the irreverence which prevailed when it was made; and in fact its wording is based upon that of a pre-Reformation order which coexisted with the practice of reservation (Lyndwood, *Provinciale*, lib. iii. tit. 26, note *q*). (3) Nor can it be said that the words of the 28th Article (see above) constitute in themselves an express prohibition of reservation, strong as their evidence may be as to the practice and feeling of the time. The words are the common property of an earlier age which saw nothing objectionable in reservation for the sick. (4) It has indeed been contended (by Bishop Wordsworth of Salisbury) that reservation was not actually, though tacitly, continued under the second Prayer-Book of Edward VI., since that book orders that the curate shall "minister," and not "celebrate," the communion in the sick person's house. But such a tacit sanction on the part of the compilers of the second Prayer-Book is in the highest degree improbable, in view of their known opinions on the subject; and an examination of contemporary writings hardly justifies the contention that the two words are so carefully used as the argument would demand. Anyhow, as the bishop notes, this could not be the case with the Prayer-Book of 1661, where the word is "celebrate." (5) The Elizabethan Act of Uniformity contained a provision that at the universities the public services, with the exception of the Eucharist, might be in a language other than English; and in 1560 there appeared a Latin version of the Prayer-Book, issued under royal letters patent, in which there was a rubric prefixed to the Order for the Communion of the Sick, based on that in the first Prayer-Book of Edward VI. (see above), and providing that the Eucharist should be reserved for the sick person if there had been a celebration on the same day. But although the book in question was issued under letters patent, it is not really a translation of the Elizabethan book at all, but simply a reshaping of Aless's clever and inaccurate translation of Edward VI.'s first book. In the rubric in question words are altered here and there in a way which shows that its reappearance can hardly be a mere printer's error; but in any case its importance is very slight, for the Act of Uniformity specially provides that the English service alone is to be used for the Eucharist. (6) It has been pointed out that reservation for the sick prevails in the Scottish Episcopal Church, the doctrinal standards of which correspond with those of the Church of England. But it must be remembered that the Scottish Episcopal Church has an additional order of its own for the Holy Communion, and that consequently its clergy are not restricted to the services in the Book of Common Prayer. Moreover, the practice of reservation which has prevailed in Scotland for over 150 years would appear to have arisen out of the special circumstances of that Church during the 18th century, and not to have prevailed continuously from earlier times. (7) Certain of the divines who took part in the framing of the Prayer-Book of 1661 seem to speak of the practice as though it actually prevailed in their day. But Bishop Sparrow's words on the subject (*Rationale*, p. 349) are not free from difficulty on any hypothesis, and Thorndike (*Works*, v. 578, Library of Anglo-Catholic Theology) writes in such a style that it is often hard to tell whether he is describing the actual practice of his day or that which in his view it ought to be. (8) There appears to be more evidence than is commonly supposed to show that a practice analogous to that of Justin Martyr's day has been adopted from time to time in England, viz., that of conveying the sacred elements to the houses of the sick during, or directly after, the celebration in church. And in 1899 this practice received the sanction of Dr Westcott, then bishop of Durham. (9) On the other hand, the words of the oath taken by the clergy under the 36th of the Canons of 1604 are to the effect that they will use the form prescribed in the Prayer-Book and none other, except so far as shall be otherwise ordered by lawful authority; and the Prayer-Book does not even mention the reservation of the Eucharist, whilst the Articles mention it only in the way of depreciation.

The matter has become one of no little practical importance owing to modern developments of English Church life. On the one hand, it is widely felt that neither the form for the Communion of the Sick, nor yet the teaching with regard to spiritual communion in the third rubric at the end of that service, is sufficient to meet all the cases that arise or may arise. On the other hand, it is probable that in many cases the desire for reservation has arisen, in part at least, from a wish for something analogous to the Roman Catholic customs of exposition and benediction; and the chief objection to any formal practice of reservation, on the part of many who otherwise would not be opposed to it, is doubtless to be found in this fact. But however that may be, the practice of reservation of the Eucharist, either in the open church or in private, has become not uncommon in recent days.

The question of the legality of reservation was brought before the two archbishops in 1899, under circumstances analogous to those in the Lambeth Hearing on Incense (*q.v.*). The parties concerned were three clergymen, who appealed from the direction of their respective diocesans, the bishops of St Albans and Peterborough and the archbishop of York: in the two former cases the archbishop (Temple) of Canterbury was the principal and the archbishop of York (Maclagan) the assessor, whilst in the latter case the functions were reversed. The hearing extended from 17th to 20th July; counsel were heard on both sides, evidence was given in support of the appeals by two of the clergy concerned and by several other witnesses, lay and clerical, and the whole matter was gone into with no little fulness. The archbishops gave their decision on 1st May 1900 in two separate judgments, to the effect that, in Dr Temple's words, "the Church of England does not at present allow reservation in any form, and that those who think that it ought to be allowed, though perfectly justified in endeavouring to get the proper authorities to alter the law, are not justified in practising reservation until the law has been so altered." The

archbishop of York also laid stress upon the fact that the difficulties in the way of the communion of the sick, when they are really ready for communion, are not so great as has sometimes been suggested.

Resiczabánya (*Resicza*), a mining town of south Hungary, in the county of Krassó-Sözrény. In the neighbouring coal and iron mines, and in the forges and iron-works belonging to the Austrian State Railway Company, above 3000 workmen are employed. In the vicinity is the bath and sanatorium of Anina. Population (1891), 10,164; (1901), 11,770.

Respiratory System. See PATHOLOGY and PHYSIOLOGY.

Retford, East, a municipal borough and market-town, Nottinghamshire, England, in the Bassetlaw parliamentary division of the county, 36 miles by rail north-east of Nottingham. A scheme of drainage to cost £44,000 has been undertaken. Swimming baths were built in 1896 by the corporation at a cost of £3000. Population of the municipal borough (1881), 9748; (1901), 12,339.

Réunion, a French island and colony in the Indian Ocean, 130 miles south-west of Mauritius and 371 east of Madagascar. It is elliptic in form; its greatest length is 45 miles, and greatest breadth 32 miles; and it has an area of about 1000 square miles. In 1878 the population amounted to 183,529; in 1898 to 173,230. The falling off is entirely due to the economic troubles which have weighed on the island since the extension of sugar production in Europe. Of the population in 1898, 143,000 were of French nationality; this number included 2400 Europeans or descendants of the old colonists, the remainder being negroes and of mixed race. The foreign element consisted of 30,000 imported labourers, of whom from 15,000 to 16,000 were from India, 14,000 from Africa, and about 1000 from China. The number of labourers from India has decreased since 1882, when the Indian Government ceased to authorize the sending of coolies for service on the plantations. The number in Réunion in 1887 was 26,400, of whom 17,600 were men. It is remarkable that the birth-rate of these Indians should be lower than their death-rate. Réunion is administered by a governor, who has under his orders a director of the interior and a *procureur général*, and is assisted by a privy council. The elective general council sits at St Denis, and the island sends a senator and two deputies to the French Parliament. The island is divided into two arrondissements, the Windward with five cantons and nine communes, and the Leeward with four cantons and seven communes. The important towns are St Denis, which had, in 1881, 30,835, and in 1899, 32,850 inhabitants, and which has a bishopric, a court of first instance, and an appeal court; St Pierre (27,901); St Paul (20,000); and St Louis (13,300).

Agriculture.—The area of the cultivated lands is estimated at 148,200 acres (or 230 square miles), of which 86,450 acres are under sugar-cane, the remainder being under either alimentary produce (maize, manioc, potatoes, haricots) or colonial produce (coffee, vanilla, cacao). The sugar-cane and coffee represent the essential agricultural wealth of the colony, though both labour under serious difficulties. The sugar crop in 1860 amounted to 68,000 tons; in 1889, to 28,000 tons; but in 1897 rose to 45,000 tons. The coffee harvest about the middle of the century reached 60,000 cwt., had fallen to 3800 cwt. in 1883, but has since risen to 14,000 cwt. This diminution is due partly to foreign competition, partly to diseases of the coffee plant. On the other hand, the cultivation of vanilla has made steady progress since 1848. In that year the production amounted to 110 ℔; in 1873 it reached 44,000 ℔; in 1885, 110,000 ℔; in 1897, 220,000 ℔; but this enormous increase has caused a fall in the prices. The cacao yield is still about 6600 ℔; cinchona cultivation is profitable, unlike cotton-growing, which has not succeeded. The forests formerly extended all over the island; now they only cover about 200 square miles, and the administration is attempting to replant the higher circles, Salazie among others, with eucalyptus and caoutchouc trees. The number of live stock is small and tends to diminish, comprising only 2500 horses, 8000 asses and mules, 8000 oxen, 28,000 pigs, 28,000 goats and sheep. Réunion possesses many fowl, and agriculture is held in esteem.

Industries.—Although the sand on the beach contains ferruginous elements, no mining enterprise is carried on. The island has warm springs at Cilaos (3500 feet), at Salazie (2600 feet), and at Mafatte (1850 feet), and these places form so many sanatoria. There are works for sugar, rum, flour, and for plaiting straw for hats. Many of the sugar factories, however, have disappeared, ruined by outside competition.

Commerce.—The total trade amounted in 1860 to the value of £4,464,000 (the highest during the century); in 1880, to £2,394,000; in 1900, to £1,533,240. In 1900 the imports amounted to £883,570 (£547,700 from France) and the exports to £698,500 (£649,670 to France, £33,710 to French colonies, and the remainder to Mauritius). France sent to the colony in 1897 cottons (£56,000), wines (£68,000), salt fish (£22,280), utensils (£12,680), furs (£18,920), toys (£17,760), machinery (£8960), and buys from the colony, sugar (£490,000), vanilla (£80,000), sago (£25,040), spirits (£24,000), oils (£16,400).

Shipping.—The shipping movement in 1900 comprised 138 vessels of 189,625 tons entered, and 135 of 188,308 tons cleared. Of these, 95 of 151,650 tons and 93 of 151,126 tons respectively were under the French flag. The ports are those of St Pierre and of Pointe des Galds (opened in 1886). St Denis and St Paul have, besides, open roadsteads.

Communications.—The island has 199 miles of national roads and many local roads. The railway, 83¼ miles in length, opened in 1882 between St Benoit and St Pierre, was taken over by the State in 1887, in consequence of forfeiture by the company. At the latter date the annual receipts amounted to no more than £33,880, and this condition has scarcely improved. Réunion is connected by a regular service of the Messageries Maritimes with Marseilles. The distance is 6637 miles, and the passage 23 to 29 days.

Finance.—The budget of the island amounts to £332,000, of which £178,800 is contributed by the mother country. This subsidy has almost doubled since 1885, in which year it did not exceed £94,000.

DU BUISSON. *Île de la Réunion*. St Denis de la Réunion, 1889.—LEVASSEUR. *La France*. T. ii. Paris, 1893. (P. L.)

Reus, a town of Spain, province of Tarragona, important railway station; its port, Salou, is 4 miles off, on the Mediterranean. Population, 26,752 in 1897. It has suburbs full of villas, with gardens extending over several thousand acres, all well irrigated. There is an active trade in the agricultural products of the fertile region around the city. The local industries, that have been important since the Middle Ages, developed considerably in the last quarter of the 19th century. They include (besides cotton, linen, and woollen goods) silk, alcohol, leather, flour, ceramics, mosaics, soap, earthenware, jams, wine, shoemaking, and refineries. The town has important flour, wine, and fruit export houses. There is a model farm belonging to the municipality in the suburbs. Reus has excellent primary, normal, and higher-grade schools, many private and religious schools, an academy of fine arts, and public library. The new town has continuously spread outside the promenades. Marshal Prim was a native of Reus. The hospitals and foundling refuge, the institute, and the town-hall are handsome modern buildings. The inhabitants are famous for their enterprising spirit and laborious habits, and Reus is considered second only to Barcelona in the Lancashire of Spain for its manufacturing success.

Reusch, Franz Heinrich (1823–1900), Old Catholic theologian, was born at Brilon, in Westphalia, on 4th December 1823. He studied general literature at Paderborn, and theology at Bonn, Tübingen, and Munich. The friend and pupil of Döllinger, he took his degree of Doctor in Theology at Munich, the university of which Döllinger was so long an ornament. He was ordained priest in 1849, and was immediately afterwards made chaplain at Cologne. In 1854 he became *privat-docent* in the exegesis of the Old Testament in the Catholic Theological Faculty at Bonn; in 1858 he was made extraordinary, and in 1861 ordinary, professor of theology in the same university. From 1866 to 1877 he was editor of the *Bonner Theologisches Literaturblatt.* In the controversies which followed upon the proclamation of the Infallibility of the Pope, Reusch attached himself to the party of his leader Döllinger, and he and his colleagues Hilgers, Knoodt, and Langen were interdicted by the archbishop of Cologne in 1871 from pursuing their courses of lectures. In 1872 he was excommunicated. For many years after this he held the post of Old Catholic *curé* of Bonn, as well as the position of vicar-general to the Old Catholic Bishop Reinkens, but resigned both in 1878, when, with Döllinger, he disapproved of the permission to marry granted by the Old Catholic Church in Germany to its clergy. From that time he retired into lay communion, but continued to give lectures as usual in the Old Catholic Faculty of Theology in the University of Bonn, and to write on theological subjects. He was made rector of that university in 1873. In 1874 and 1875 he was the official reporter of the memorable Reunion Conferences held at Bonn in those years and attended by many distinguished theologians of the Oriental and Anglican communions.

Reusch was a profound scholar, an untiring worker, and a man of simple and lovable character, clear in expression and exact in method. His works were voluminous, and among them were contributions to periodical literature, and especially to the *Revue Internationale de Théologie*, a review started at Bern at the instance of the Old Catholic Congress at Lucerne, in order to promote intercommunication and eventual reunion between the Churches opposed to the papal claims. Among his works are several on the Old Testament, and chief among these is a manual of introduction to it, which passed through four editions; a pamphlet on *Die Deutschen Bischöfe und der Aberglaube;* and another on the falsifications to be found in the treatise of Aquinas against the Greeks; as well as essays on the history of the Jesuit Order, and a book of prayers, which passed through three editions. But his fame will mainly rest on the works which he and Döllinger published jointly. These consisted of a work on the Autobiography of Cardinal Bellarmine, the *Geschichte der Moralstreitigen in der Römisch-Katholischen Kirche seit dem XVI. Jahrhundert*, and the *Erörterungen über Leben und Schriften des hl. Liguori.* During the last few years of his life he was smitten with paralysis and was unable to work. His last contribution to literature was an article on the inspiration of the Scriptures, communicated to the *Revue Internationale de Théologie* of April 1894. He died 3rd March 1900, leaving behind him in manuscript a collection of letters to Bunsen about Romish cardinals and prelates, which has since been published. (J. J. L*.)

Reuss, Edouard Guillaume Eugène (1804–1891), Protestant theologian, was born at Strasburg, studied theology at Göttingen under Eichhorn, and Oriental languages at Halle under Gesenius, and afterwards at Paris under Silvestre de Sacy. From 1829 to 1834 he taught biblical criticism and Oriental languages at the Strasburg Theological School; he then became assistant and afterwards regular professor of theology at that university. The sympathies of Reuss were German rather than French, and after the annexation of Alsace to Germany he remained at Strasburg, and retained his professorship till, in 1888, he retired on a pension. He had a full mastery of both languages, and wrote sometimes in French and sometimes in German. In 1852 he published his *Histoire de la théologie chrétienne au siècle apostolique*, which gives a systematic narrative of the causes which stimulated and directed the theological labours of the first generation of Christians, with a view to linking together all the theories that form the main subject of this book. This was followed in 1863 by *L'histoire du canon des saintes écritures dans l'église chrétienne.* It was the criticism and exegesis of the New Testament which formed the subject of Reuss's earlier labours—in 1842, indeed, he had published in German a history of the books of the New Testament; but after a time he turned his attention also to Old Testament criticism, a study for which he was especially fitted, owing to his profound knowledge of Hebrew. In 1881 he published in German his *History of Old Testament Scripture*, a veritable encyclopædia, which embraces the public and domestic history of Israel, the literature and thought, art, archæology, and general life of the people from the dawn of history till the taking of Jerusalem by Titus.

Reuss, who died at Strasburg on the 15th of April 1891, belonged to the more modern section of the Liberal party in the Lutheran Church. His critical position was to some extent that of Graf and Wellhausen, allowing for the circumstance that he was in a sense their forerunner, and was actually for a time Graf's teacher. His earliest views were summed up in the formula "The Prophets are earlier than the Law, and the Psalms are later than both," a statement that, with the necessary additions in detail, expresses the present position of Old Testament criticism. For many years Reuss edited the *Beiträge zu den theologischen Wissenschaften.* With Baur and Cunitz, and after their death alone, he edited the monumental edition of Calvin's works. His critical edition of the Old Testament appeared a year after his death. (A. Z.)

Reuss, two principalities of Germany, in Thuringia. (1) Reuss the Elder, with an area of 122 square miles, and population (1885), 55,904; (1900), 68,287. Density, 559 inhabitants to the square mile. Of the total, 98 per cent. were in 1895 Evangelical Lutherans. In 1900 there were 1953 horses, 14,447 cattle, 10,118 pigs, and 2337 sheep. In 1895 there were 5225 farms, of which 4552 were each less than 25 acres in extent. In 1900 the state revenue and expenditure were balanced at £77,050. There is no public debt. The contribution to the imperial exchequer was fixed at £33,980 for the year 1900. (2) Reuss the Younger, with an area of 319 square miles, and population (1885), 110,598; (1900), 138,993, the density being 435 inhabitants to the square mile. Except for 2090 Roman Catholics, 181 Jews, and 477 "others," the people in 1895 were all Protestants. In 1900 there were in the principality 34,009 cattle, 27,013 pigs, 8929 sheep, and 4579 horses. Out of a total of 8558 farms in the principality in 1895, no less than 7086, or 82·8 per cent., were each less than 25 acres. For the period 1899–1901 the public revenue and expenditure were each fixed at £136,570 annually. The public debt was £52,000 in 1899, and the contribution to the imperial exchequer in 1900 was fixed at £66,545.

Reutlingen, a town of Würtemberg, Germany, 36 miles by rail south of Stuttgart. The church of St Mary

was restored in 1899–1900. There are a textile school, a school for women's work, and an agricultural school. It has multifarious industries. Population (1900), 21,481.

Revel, or Reval, a fortified seaport, State dockyard, and district town of Russia, in the government of Esthonia, 249 miles by rail west-south-west of St Petersburg. Its population in 1881 was 50,490, and in 1897, 64,578, of whom half were Esthonians and 30 per cent. Germans. It is the seat of a branch Board of the Admiralty and of the administration of the Baltic lighthouses. Its port, which is one of the most important in Russia, has a depth of from 4 to 6 fathoms, and a roadstead $3\frac{1}{2}$ miles wide; this is not quite protected from the north-west winds, and freezes nearly every winter, but is annually visited by about 400 foreign ships and about 1400 vessels engaged in the coasting trade. The exports, chiefly grain, timber, flax, and hemp, were valued at 33,826,000 roubles in 1897; and the imports, chiefly manufactured goods and machinery, at 56,305,000 roubles. There is considerable trade with Finland. Baltic Port is a sort of annex to the port of Revel.

Revelstoke, British Columbia, on the Canadian Pacific Railway, where it crosses the Columbia river. It is a divisional point of the railway, and the junction for connexion with the Arrow Lakes and the West Kootenay district. It is also a distributing point for the mines to the north and the important and promising section of country known as the Trout Lake district to the south. Population (1800), 1600.

Revere, a town of Suffolk county, Massachusetts, U.S.A. It is a few miles north-east of Boston, of which it is a suburb, in the eastern part of the state, on a line of the Boston and Maine Railroad. Population (1880), 2263; (1890), 5668; (1900), 10,395, of whom 2917 were foreign-born.

Revilla Gigedo, an uninhabited insular group belonging to Mexico, in the North Pacific, about 420 miles from the coast of the state of Colima, 18° N. and 112° W. It comprises the large island of Socorro (San Tomas), 25 miles by 12, and the three scattered islets of San Benedicto, Roca Partida, and Clarion, with a total area of 320 square miles. It is probably of volcanic formation, with an extinct cone 3660 feet high in Socorro. The archipelago, which takes its name from a Spanish viceroy who ruled from 1746 to 1755, presents some remarkable zoological features, comprising several birds and reptiles allied to, but of different species from, those of the mainland.

Rewa, a native state of India, in the Baghelkhand agency. Area, about 10,000 square miles. Population (1881), 1,305,124; (1891), 1,508,943. Many of the inhabitants belong to the Gonds and Kols. Gross revenue (1897–98), Rs.11,45,915, of which Rs.6,31,828 was derived from land, Rs.1,70,928 from customs, and Rs.1,73,660 from forests. Expenditure, Rs.18,20,343, of which Rs.3,24,469 was for palace, Rs.2,59,188 for army, Rs.1,45,514 for public works, and Rs.4,16,253 for famine relief.

The Maharaja Raman Singh was born in 1876 and succeeded in 1880. During his minority the administration was reformed. The southern portion of the state is crossed by the branch of the Bengal-Nagpur Railway from Bilaspur to Katni, which taps the Umaria coal-field, yielding 150,000 tons, now under the management of the state. A branch line from Sutna on the East Indian Railway, the residence of the political agent for Baghelkhand, to the town of Rewa, has recently been constructed as a famine relief work. The state suffered from famine in 1896–97, and again to a less extent in 1899–1900; but on both occasions adequate measures of relief were provided.

The town of Rewa is 131 miles south of Allahabad. Population (1891), 23,626. It has a high school, with 432 pupils; also the Victoria and zenana hospitals, and a model gaol. The town of Sutna or Satna, headquarters of the Baghelkhand political agency, has a population (1891) of 6771.

Rewa Kantha, a political agency or collection of native states in India, within the Gujarat division of Bombay; stretching for about 150 miles between the plain of Gujarat and the hills of Malwa, from the river Tapti to the Mahi, crossing the Nerbudda or Rewa, from which it takes its name. The number of separate states is 61, many of which are under British jurisdiction. The only important one is Rajpipla (*q.v.*). Total area, 4980 square miles. Population (1881), 549,892; (1891), 733,506. In 1901 the population was 478,889, showing a decrease of 35 per cent., due to the results of famine. Estimated gross revenue, Rs.27,07,329; tribute (mostly to the Gaekwar of Baroda), Rs.1,16,700; number of police, 1167; number of schools, 185, with 9779 pupils in 1897–98. Many of the inhabitants belong to the wild tribes of Bhils and Kolis. The Panch Mahals were constituted a British district out of this tract in 1876.

Rewari, a town of British India, in the Gurgaon district of the Punjab, situated in 28° 12′ N. and 70° 40′ E., 32 miles south-east of Gurgaon. It has a railway station. Population (1881), 23,972; (1891), 27,934; municipal income (1897–98), Rs.57,161. It is on an ancient site, formerly a native capital, and at one time a British cantonment. It is now an important centre of trade, being the junction for the Rewari-Ferozepore branch of the Rajputana Railway. There are manufactures of brass-ware and turbans, and two factories for ginning and pressing cotton. There is a municipal high school.

Reyer, Ernest (1823–——), French composer, was born at Marseilles, 1st December 1823. At the age of sixteen he went to Algeria, and remained there some years. The outcome of his residence there was a symphonic ode entitled *Le Sélam*, the musical orientalism of which had, unluckily for him, already been anticipated by Félicien David in *Le Désert*. *Maître Wolfram*, a one-act opera from his pen, was produced at the Opéra Comique in 1854; and in 1858 *Sacountala*, a ballet of his composition, figured on the bills of the Opéra. It was the production of *La Statue* at the Théâtre Lyrique in 1861 that brought Reyer's name prominently before the public. This work is notable for the sincerity of its accents, and also for the picturesqueness of its Eastern colouring. Reyer was now to wait several years before obtaining a real and permanent success. *Erostrate*, an opera produced at Baden-Baden in 1862, and given at the Paris Opéra some ten years later, was a failure. The composer had in the meanwhile set to work on an opera founded upon the Nibelungen-lied. *Sigurd*, the subject of which is the same that inspired Wagner in *Siegfried* and *Götterdämmerung*, lay on hand for a long while, being at last produced for the first time in Brussels in 1884, and subsequently brought out at the Paris Opéra, where it has since remained in the *répertoire*. Despite crushing comparisons, *Sigurd* is a work of great value, revealing high and noble aspirations, and displaying its composer's elevated notions as regards the form of the "lyrical drama." *Salammbô*, Reyer's last opera, founded upon Flaubert's well-known romance, followed the same road as *Sigurd*, reaching Paris *viâ* Brussels, being produced in the Belgian capital in 1890, and meeting with emphatic success. Gluck, Weber, Berlioz, and Wagner are the composers who have exercised most influence over Reyer. An intimate friend of Berlioz, Reyer was also one of the earliest champions of Wagner in France. He is well known as a writer on music, and preceded Berlioz as musical critic to the *Journal des Débats*. Reyer is librarian of the Paris Opéra, and a member of the Institute.

Rheims (or Reims), a town of France, in the department of Marne, 97 miles from Paris by rail. It is important on account of its industries, which increased very considerably during the last quarter of the 19th century. Population (1881), 93,683; (1901), 107,773. The increase was most marked in the suburb of Les Contures on the east of the town. Wool, combed and carded in numerous establishments, is spun in 20 factories, and in 30 others woven into flannel, merino, cloth, and woollen goods of all kinds. Some of these establishments are important; for example, two machine combing mills employ more than 2000 workmen, and the whole wool industry occupies in all 24,000 hands. Rheims possesses an office for the *conditionnement* of wool, similar to that in Lyons for silk. This office, which determines the loss of weight resulting from the drying of the wool, registers annually about 8800 tons of combed and spun wool. The woollen industry has, however, been on the decline. In 1898 the measuring house dealt with only 123,097 pieces measuring 4,575,150 metres, as compared with 275,333 pieces measuring 12,941,193 metres in 1890, the decline having been continuous; but in 1899, 137,898 pieces measuring 6,272,843 metres were dealt with. Fifteen dyeworks employ 1000 workers, and one of these factories annually treats 50,000 pieces, each 110 yards in length. Rheims is also the most important market for raw wool in France. Transactions annually reach a value of from £5,000,000 to £6,000,000, half of which is appropriated by the industries of Rheims itself. Fifty firms trade in champagne wines, and employ 16,000 workmen, exporting in 1899 29,368,825 bottles—one-quarter of them for France—and barrels totalling in weight 11,893 tons. The value of the trade in this commodity reaches £4,000,000. Rheims, an important railway centre, is surrounded by a chain of detached forts measuring 39 miles and extending as far as Épernay. A large garrison occupies the town and forts. The Musée Lapidaire of the archiepiscopal palace has been transferred to the cloister of St Rémi, and the courtyard of the hospital which occupies the old abbey of that name was in 1898 enriched with a handsome sculptured fountain. A statue of Jeanne d'Arc has been erected, and in 1888 a monument to the Abbé de la Salle, founder of the order of Christian Brothers.

Rheinberger, Joseph Gabriel (1839–1901), German composer, was born at Vaduz, Liechtenstein, 17th March 1839. His musical abilities were manifested so early that he was appointed organist of the parish church when he was but seven years old, an appliance being specially attached to the organ by which the pedals could be brought within reach of the child's feet. A three-part Mass composed by him was performed in the following year. He was taught at first by Philipp Schmutzer, choir director at Feldkirch; he entered the Munich Conservatorium in 1851, and remained there till 1854 as a pupil of Professor E. Leonhard for piano, Professor Herzog for organ, and J. J. Maier for counterpoint. After leaving the school he had private lessons from Franz Lachner, and was appointed a professor in the conservatorium in succession to Leonhard in 1859. In 1860 he became professor of composition, and was appointed organist of the Michelskirche, a post he held till 1866. From 1854 he was accompanist, and from 1864 conductor, of the Munich Oratorio Society, resigning in 1877; and from 1865 to 1867 was "répetitor" at the Hofoper. In 1877 he succeeded Wüllner as Hofkapellmeister, and from that time his attention was largely devoted to sacred music. His compositions include works of importance in every form, from the operas *Die sieben Raben* (Munich, 1869) and *Thürmers Töchterlein* (Munich, 1873) and the oratorio *Christoforus*, op. 120, to the well-known quartet for piano and strings in E flat, op. 38, the nonet for wind and strings, op. 139, and the seventeen organ sonatas, which form notable additions to the literature of the instrument. A splendid teacher, he was a master of contrapuntal effect, and had a strong sense of the different styles required for various musical forms, while the flowing, melodious character of his music, the fertility of his invention, and the brilliance of his technique, gained for him the title of the "Raff of Southern Germany." He died in November 1901.

Rheine, a town of Prussia, province of Westphalia, on the Ems, at the point where it becomes navigable, 29 miles by rail west of Osnabrück. It is the seat of cotton industries, and has also manufactures of jute, machinery, tobacco, and flour. Population (1900), 10,373.

Rheydt, a town of Prussia, Rhine province, 19 miles west by south of Düsseldorf by the railway to Aix-la-Chapelle. The manufacture of velvet has now been added to the industries. Population (1900), 34,034.

Rhine, the principal river of Germany, flowing also through Switzerland and Holland. The traffic on this stream has increased enormously since the foundation of the German empire. In 1871 the traffic between the Rhine ports and the seaports of the Baltic and North Seas was confined to three small vessels which plied between Cologne and London, though there was of course a much larger purely river traffic. A dozen or fifteen years later vessels of 800 to 1200 tons began to make the voyage between Cologne and London, and afterwards the carrying capacity was increased first to 1600 tons, and subsequently to 1750 tons. In 1899 this particular traffic gave occupation to 32 vessels of 24,240 tons, and the bulk of goods they carried amounted to 105,540 tons; while there were in addition 105 lighters varying in capacity from 70 to 950 tons.

Besides London, Hamburg, Bremen, and the chief Baltic ports as far as Riga and St Petersburg participated in this traffic. The boats which ply up and down the river itself, without venturing upon the open sea, are mostly craft of 100 to 200 tons, owned in the great majority of cases by their captains, men principally of German or Dutch nationality. This fleet is computed to number some 8500 craft, with an aggregate capacity of over 2 million tons, of which about one-tenth are steamships. The traffic at the chief German ports of the river aggregated 4,489,000 tons in 1870, but by 1900 this had grown to a total of 17,000,000 tons, thus distributed:—Ruhrort, 6,512,000 tons; Duisburg, 3,000,000 tons; Cologne, 1,422,000 tons; and Mannheim, 6,021,000 tons. And these are not the only ports on the river; a large trade is also done at Kehl (a new port), Maxau (for Carlsruhe), Ludwigshafen, Mainz, Bonn, Rotterdam, and a host of smaller places. The amount of traffic which passed the town of Emmerich near the Dutch frontier, both ways, increased from an annual average of about 6 million tons in 1881–85 to over 21½ million tons in 1899. Notwithstanding the inherent difficulties of construction caused by the great variations in the level of the stream, amounting sometimes to 20 feet or more, the chief ports of the Rhine are admirably constructed, and well equipped with modern contrivances for loading and unloading vessels. Boats carrying as much as 600 tons are often able to proceed as far up stream as Strasburg, and smaller craft get as far as Hüningen, a little above Basel. Large passenger boats ply regularly between Mainz and Düsseldorf, and sometimes extend their journeys as high up as Mannheim, and as far in the other direction as Rotterdam. The efforts of the river authorities are being directed to the deepening and improvement of the navigable channel from the sea to Strasburg, the low-water depths aimed at being 10 feet from Rotterdam to the German frontier, and 10 feet thence to Cologne; 8 feet 3 inches from Cologne to St Goar, and 6 feet 6 inches from St Goar to Mannheim. At present the Rhine in Holland has a depth of about 9 feet and a width of 1200 to 1300 feet, though the Merwede branch exceeds this depth by 8 inches. Altogether a sum approaching £2,500,000 was spent in Holland within the latter part of the 19th century on the improvement of the Rhine and its principal arteries. Above Mannheim the depth of the stream is always less than 5 feet, and

generally varies between that figure and 4 feet 6 inches. The difficulty of ascending the rapids near Bingen is usually surmounted by the help of steam hauling machinery placed on the bank, though powerful tugs are also coming into use for this purpose. The work of blasting out the rocks which at that spot projected in the bed of the river, begun in 1830, was continued down to the year 1887, so that now there are two navigable channels of sufficient depth for all vessels which ply up and down that part of the stream. The navigability of some of the chief German tributaries of the Rhine has also been improved. For instance, in the years preceding 1886 the Main was canalized for 20 miles above Frankfort, the depth being increased from 2⅜ feet to 8¼ feet at a cost of £400,000. In addition three new canals have still further increased the usefulness of this great waterway. The first of these is the Merwede canal, which connects Amsterdam with the Waal at Gorinchem (Gorkum). The next connects Strasburg with the Rhine—the Strasburg–Rhine canal, 4 miles long, 40 to 60 feet wide and 8 feet deep. The third is the Rhine–Weser–Elbe canal, which consists of three divisions—the middle division, coinciding with the Dortmund–Ems canal (see Ems), opened in 1899; the eastern division, to coincide with the Midland canal, which is only in part constructed; and the western division, which exists only in the plans, of which there are two—(*a*) the South Emscher canal, from the Rhine at Neuenkamp, near Duisburg, to the Dortmund–Ems canal at Herne, 27 miles long; and (*b*) the Lippe canal, 40 miles long, from the Rhine at Wesel along the river Lippe to the Dortmund-Ems canal at Datteln. These projected works would give a continuous waterway from the busiest mining and industrial districts of Westphalia to the extreme east of the empire. In 1884 the German Reichstag appointed a commission to inquire into the "relations" of the Rhine, that is, its tendency to cause floods, the distribution of its precipitation, its fall in various parts of its course, and so forth. The results of these investigations were published in the elaborate work, *Der Rheinstrom und seine Nebenflüsse* (Berlin, 1889), and in the further *Bericht der zur Untersuchung der Rheinstromverhältnisse niedergesetzten Reichskommission* (1891). The Rhine is no longer the barrier between east and west, but is spanned by railway bridges in about thirty places, notably at Dordrecht, Zalt-Bommel, and Nimeguen in Holland; at Wesel, Duisburg, Düsseldorf, Cologne, Bonn, Coblenz, Mainz, Mannheim, Spires, Kehl, Schaffhausen, and Constance in Germany; and at Basel and Ragaz in Switzerland.

Rhine Province. See Prussia, Rhenish.

Rhode Island, one of the six New England states, the smallest in the American Union, and the last of the original thirteen to adopt the Federal Constitution, lying between 41° 18′ and 42° 3′ N. and 71° 8′ and 71° 53′ W. Its greatest length is 48 miles; its greatest width 37 miles. Its area covers 1250 square miles, of which 165 square miles is water surface. It is bounded on the N. and E. by Massachusetts, on the W. by Connecticut, and on the S. by the Atlantic Ocean. Narragansett Bay, running north 30 miles, divides it into two unequal parts. In the bay are many islands; the largest is Rhode Island, whence the state derives its name. Block Island lies 10 miles out in the ocean. The surface is hilly, though the highest elevation, Durfee Hill, Gloucester, is only 805 feet above the sea. The climate is not as changeable as that of other parts of New England. Narragansett Bay tempers the atmosphere, and the cold east winds that afflict Boston, 40 miles away, are rarely felt. Newport and the towns upon the coast are warmed by the influence of the Gulf Stream.

Population.—In 1880 the population was 276,531; in 1890, 345,506; in 1895, 384,758; and in 1900 it was 428,556. The population, therefore, increased 24 per cent. from 1890 to 1900, and the density per square mile rose from 328·1 to 407. Rhode Island is consequently the most densely peopled state in the Union. Of the total population in 1900, 210,516 were males and 218,040 were females, constituting respectively 49·1 per cent. and 50·9 per cent. of the total population, as compared with 48·6 per cent. and 51·4 per cent. respectively in 1890. The foreign-born population, which in 1850 constituted 16·5 per cent. of the population, numbered in 1890, 106,305 (or 30·8 per cent.), and in 1900, 134,519 (or 31·4 per cent.). Of the native-born white population in 1900, nearly one-half (140,292 out of 285,278) were sprung from parents of whom at least one was of foreign origin. Providence was slightly above the average percentage in its foreign-born population. Of the foreign-born population in 1895 Ireland contributed the largest number, followed by Canada, England, Scotland and Wales, Italy, Sweden, Germany, Russia, Portugal, in the order named. The Canadians were mostly of French descent. The coloured population, which in 1748 amounted to 9·4 per cent. of the total, has become relatively stationary, being 2·2 per cent. of the total both in 1890 and in 1900. Out of 127,144 adult males in 1900, 11,675 were illiterate (unable to write), of whom 9932 were foreign-born.

The state is divided into five counties. There are 5 incorporated cities: Providence, the capital (175,597), Pawtucket (39,231), Woonsocket (28,204), Newport (22,034), Central Falls (18,167); 32 towns (of which 12 contain more than 4000 inhabitants); and 1 "district." Newport is the most fashionable watering-place in the Union. Bristol is famous for its yacht-building establishments. The defenders of the "America Cup" have been built there for several years. The urban population in 1890, designating as such the total population of all places of more than 4000 inhabitants, was 310,335, or 89·8 per cent. of the total; in 1900 it was 392,509, or 91·6 per cent.—a higher ratio of urban to total population than exists in any other state of the Union. The death-rate of the entire state in 1890 was 20·9; in 1900 it was 19·1.

In *manufactures*, notwithstanding its small size, Rhode Island is one of the most important states of the Union.

	1890.	1900.	Increase, per cent.
Number of establishments	3377	4189	24
Capital	$126,483,401	$183,784,587	45·3
Wage-earners (average number)	81,111	96,528	19
Total wages	$33,239,313	$41,114,084	23·7
Value of products	142,500,625	184,074,378	29·2

In 1890 the wage-earners engaged in manufactures comprised 23·5 per cent. of the population; in 1900, 22·5. It is interesting to note that while the number of men, 16 years of age and over, among the wage-earners increased nearly 30 per cent., the number of women of like age so employed increased only 5·4 per cent. (while their total wages increased 20·4 per cent.), and the number of children under 16 so employed decreased 13·5 per cent. (although their total wages decreased only 1·8 per cent.). The three most important manufacturing products of the state are textiles, jewellery, and foundry and machine-shop products. There were 218 establishments engaged in the manufacture of textiles, with products valued at $78,133,258; 214 in the manufacture of jewellery, with products valued at $13,320,620; and 149 in the manufacture of foundry and machine-shop products, which were valued at $13,269,086. Under the general group of textile industries are included the manufacture of cotton goods (products, $26,435,675), of worsted goods (products, [illegible]), of woollen goods (products, $5,330,550), dyeing and finishing textiles (products, $8,484,878). In the manufacture of cotton goods the state in 1900 was third in the United States. In 1895, 1,924,486 spindles were running and 43,106 looms; one establishment in Providence contained more than 400,000 spindles. Providence is the first city in the United States in the manufacture of jewellery.

Other Industries.—Underlying Narragansett Bay and the land east of it are extensive coal deposits, the extreme eastern bed of anthracite in the United States. Graphite is mined in Cranston for blast furnaces. Magnetic iron is found in Cumberland. At Lime Rock, Lincoln, the best lime in America has been steadily produced for more than 200 years. In the southern part of the state are extensive granite quarries. Westerly granite is universally known and employed in monumental work. The fisheries reported in 1895 an invested capital of $921,429, and

the yearly product is more than $1,000,000. Agricultural productions are not important, though market-gardening is carried on on a large scale not far from Providence, large crops being secured by irrigation. In 1900 there were 5948 farms in the state, comprising altogether 455,602 acres, or 67·6 per cent. of the total land surface of the state. The total value of farm property in 1900 was $26,989,189, and of farm products (1899) $6,333,864.

Transportation.—In 1899 there were 548 miles of steam and 182 miles of electric railways. More than 500 miles of steam railways are controlled by the New York, New Haven, and Hartford Railroad, which corporation also controls the steamboat lines running from Providence to New York. Steamships, owned largely outside the state, run from Providence to Philadelphia, Baltimore, Norfolk, Savannah, and Jamaica, W.I. The total steam tonnage of the state (not including yachts) is 22,391·13.

Finances.—The total valuation of property was $399,897,333. The state tax (18 c. per $100) is always included in levying local taxes. The state debt, 1st January 1899, was $2,300,000. The town and city debt was $28,612,407. In January 1900 the banks of the state, with their capital and deposits, were as follows :—

Banks.	Capital (including Surplus).	Deposits.
59 National	$24,222,980	$26,587,874
6 State	916,675	837,220
8 Trust companies	4,926,909	27,745,177
35 Savings	...	73,186,624
108	$30,066,564	$128,356,895

Depositors in savings banks, 146,321.

Education, Religion, &c.—The present school system is largely the work of the late Henry Barnard. The attendance in 1899 was 65,527 ; the number of teachers, 1858. The schools are supported by the towns and cities and not by the state, the "Permanent School Fund" amounting (December 1899) to only $245,525. The state normal school and the Rhode Island School of Design are situated in Providence. In Kingston is the Rhode Island College of Agriculture and Mechanic Arts, with a faculty of 23 and 180 students in 1899. Brown University is the chief educational institution. Though it is under Baptist control, it is unsectarian in spirit. Within ten years the faculty has increased from 26 to 92, the students from 285 to 925, and the endowment has been more than doubled. Two million dollars was secured by subscriptions for its permanent fund in 1900–1901 A women's college is connected with the university. Its students are taught in separate classrooms by the university professors, and receive degrees on the same terms as men. The system is not one of co-education, but of coordinate education. Of religious denominations, the Roman Catholic has 52 churches, with 96,755 members, and property valued at $2,295,700 ; the Baptist (Regular) has 75 churches, with 12,055 members, and property valued at $1,151,960 ; the Protestant Episcopal has 63 churches, with 9458 members, and property valued at $1,189,700 ; the next denominations in order are : Congregational, Methodist Episcopal, Baptist (Free Will) and Unitarian. Of charitable institutions, the principal are the Butler Hospital for the Insane and the Rhode Island Hospital, in Providence, and the soldiers' home, in Bristol. In Cranston, on the "state farm" of 533 acres, are the reformatory and penal institutions of the state, the workhouse, the hospital for insane, the almshouse, the prison, the Providence county gaol, and the reform school ; the number of inmates in 1899 was 2193.

History and Politics.—Roger Williams was the founder of the colony. Ordered in 1636 to leave the colony of Massachusetts Bay because of religious opinions, he fled to the "Narragansett country," and at Providence founded the state, of which religious liberty was the chief corner-stone. A royal patent obtained by him limited authority exercised under it to "civil things," and a charter granted by Charles II. in 1663 provided for entire freedom in religious matters. A property qualification was required of all voters. Under this charter the state was governed until 1843. The present laws relating to suffrage were enacted in 1888 ; their chief defect is that they entail unequal representation. All towns and cities are represented in the State Senate by one senator, without regard to population. The membership of the House of Representatives is limited to 72, and each town must have one representative. But no city may have more than one-sixth of the whole number of members. Thus Providence, with 175,597 people, can have but 12 members, one to 14,633 persons, while West Greenwich has one representative for 721 inhabitants, and the twelve smallest towns, with 14,657 people, have as many representatives as Providence. All state officers are elected annually. The governor has no veto power. The state is Republican in politics ; McKinley received a plurality of 22,978 votes over Bryan in 1896, and 13,972 votes in 1900. (W. H. Mu.)

Rhodes, the most easterly of the islands in the Aegean Sea, forming, with the islands of Symi, Kasos, Karpathos, Castelorizo, Tilos, and Sharki, one of the four sanjaks into which the Archipelago vilayet of Turkey is divided. The governor-general of the vilayet resides at the town of Rhodes, at the north-east extremity of the island. The facilities afforded by the lines of steamers that run from Smyrna to the islands of the Sporades and the small towns on the Asia Minor coast have destroyed the important transit trade which Rhodes formerly enjoyed. In 1900 the exports—sponges, storax oil, valonea, and fruits—amounted to £27,400, and the imports to £180,500. The population of the island comprises 7000 Moslems, 21,000 Christians, and 2000 Jews.

Rhodes, Cecil John (1853–1902), British colonial and Imperial statesman, was born on 5th July 1853, at Bishop Stortford, in Hertfordshire. His father was a clergyman, but he claimed descent from yeoman stock. His family appear to have been first known as farmers and graziers about the beginning of the 18th century. Towards the middle of that century his great-grandfather, Mr Samuel Rhodes, acquired considerable wealth, and became the possessor of a large estate at Dalston. His grandfather, Mr William Rhodes, owned a property attached to Layton Grange, in Essex, and Mr Rhodes's father, the Rev. Francis William Rhodes, afterwards succeeded to this estate. Cecil John Rhodes was the fifth son in a large family of sons and daughters. At the time of his birth his father held the living of Bishop Stortford. The boy was educated at Bishop Stortford grammar school with the intention of preparing for the Church ; but at the age of sixteen his health broke down, and in the latter part of 1870 he was sent to join an elder brother, then engaged in farming in Natal. In that year diamonds were discovered in the Kimberley fields. By the end of 1871 Mr Rhodes and his brother were among the successful diggers. The dry air of the interior restored Mr Rhodes's health, and before he was fully nineteen he found himself financially independent, physically strong, and free to devote his life to any object which commended itself to his choice.

Rhodes has left behind him an interesting record of the manner in which he was affected by the situation. He determined to return to England, and to complete his education by reading for a degree at Oxford ; but before doing so, he spent eight months in a solitary journey through the then little known parts of the country lying to the north of the Orange and Vaal rivers. He went through Bechuanaland to Mafeking, thence to Pretoria, Murchison, Middelburg, and back through the Transvaal to Kimberley. The journey, made in an ox-waggon at a rate of progression of some 15 to 20 miles a day, represented a walking tour of eight months through the vast spaces of rolling veldt which at that time filled those regions of Southern Africa. He saw one of the healthiest countries in the world barely occupied. He knew the agricultural possibilities of Natal. He knew its mineral wealth. The effect of the combined influences on his mind, in the circumstances in which he found himself, was profound. The idea took passionate possession of him that the fine country through which he moved ought to be secured for occupation by the British race, and that no Power but Great Britain should be allowed to dominate in the administration of South Africa. When he brought his self-imposed pilgrimage to an end, he had found an object to which he proposed to devote his life. It was nothing less than the governance of the world by the British race. A will exists written in Mr Rhodes's own handwriting a couple of years later, when he

was still only twenty-two, in which he states his reasons for accepting the aggrandizement and service of the British Empire as his highest ideal of practical achievement. The document begins with the characteristic sentence: "I contend that the British race is the finest which history has yet produced." The argument, continued through some twenty foolscap pages, is a clear if somewhat crude summary of the articles of faith on which the edifice of modern British Imperialism is based. It puts forward broadly, as an aim which must appeal to every elevated mind, the conception of working for the governance of the entire world by its finest race; and it ends with a single bequest of everything of which he might die possessed, for the furtherance of this great purpose. Five-and-twenty years later his final will carried out, with some difference of detail, the same intention.

The share which he allotted to himself in the general scheme was the extension of the area of British settlement in Africa, but he did not attempt to address himself immediately to public work. He returned, in accordance with his first resolve, to Oxford, where he matriculated at Oriel. In 1873 his health again failed, and he was sent back to South Africa under what was practically a death sentence. Years afterwards he saw the entry of his own case in the diary of the eminent physician whom he consulted, with a note, "Not six months to live." South Africa again restored him to health. Three years later he was back at Oxford, and from 1876 to 1878 he kept his terms. During this period he spent the Long Vacation each year in South Africa, where his large financial interests were daily increasing in importance. He was a member of the Cape Ministry when, after a further lapse of years, he kept his last term and took his degree. He did not read hard at Oxford, and was more than once remonstrated with in the earlier terms for non-attendance at lectures. But he passed his examinations; and though he was never a student in the university sense of the term, he was to the end of his life a keen devourer of books. He kept always a special liking for certain classic authors. Aristotle was the guide whom as a lad he followed in seeking the "highest object" on which to exercise the "highest activity of the soul." Marcus Aurelius was his constant companion. There exists at Grote Schuur a copy of the *Meditations* deeply scored with Mr Rhodes's marks.

CECIL RHODES.
(From a photograph by Elliott and Fry, London.)

During this Oxford time, and on to 1881, Mr Rhodes was occupied with the amalgamation of the larger number of the diamond mines of Kimberley with the De Beers Company, an operation which established his position as a practical financier and gave him an important connexion and following in the business world. This following and connexion, extended as it was by subsequent developments, was to Mr Rhodes in many of his larger political undertakings as a fighting army to a general. His enemies made it the subject of severe criticism. To many admirers who shared his ideas on public questions his connexion with the financial world and his practical success were a stumbling-block. It was often wished for him that he had "kept himself clear of all that." But this was not his own view. His ideals were political and practical. To him the making of money was a necessary preliminary to their realization, and he was proud of his practical ability in this direction. He was personally a man of most simple tastes. His immense fortune was spent in the execution of his ideals, and it has been justly said of him that he taught the world a new chapter of the romance of wealth. He rallied round him what may be called a new school of millionaires, who found in his example an inspiring suggestion for the employment of money.

In 1881 Mr Rhodes entered public life as a member of the Cape Assembly. It was the year of the Majuba settlement. South Africa was convulsed with questions which had arisen between the British and the Dutch, and leaders of Dutch opinion at the Cape ventured to speak openly of the formation of a United States of South Africa under its own flag. The British party needed a rallying-ground, and Mr Rhodes took his stand on a policy of local union combined with the consolidation and expansion of Imperial interests. He offered to Dutch and British alike the ideal of a South African Federation governing itself within the Empire, and extending, by its gradual absorption of native territories, the range of Imperial administration. Local self-government was, in his opinion, the only enduring basis on which the unity of the Empire could be built, and throughout his life he was as keen a defender of local rights as he was of Imperial unity. There was a period somewhat later in his career when this attitude on his part gave rise to a good deal of misapprehension, and his advocacy of the elimination of direct Imperial interference in local affairs caused him to be viewed in certain quarters with suspicion as a Separatist and Independent. Those who were inclined to take this view were greatly strengthened in their suspicions by the fact that at a critical moment in the struggle for Home Rule in Ireland Mr Rhodes contributed £10,000 to the funds of the Separatist party. The subsequent publication of his correspondence on the subject with Mr Parnell, who was at that time leading the Home Rule party, demonstrated, however, the essential fact that, whatever might have been the secret intentions of the extreme Irish Home Rulers, Mr Rhodes's contribution was made strictly subject to the retention of the Irish members at Westminster, and that his interest in the Irish question arose solely from a belief that the Home Rule movement, if successful in establishing the double principle of local self government combined with Imperial representation, would be, in his own words, the "commencement of changes which will eventually mould and weld together all parts of the British Empire." He remained of the opinion that the

Home Rule movement, wisely treated, would have had a consolidating and not a disruptive effect upon the organization of the Empire.

In South Africa the influence which he acquired over the local independents and over the Dutch vote was subsequently an important factor in enabling him to carry out the scheme of northern expansion which he had at heart. His first attention on entering public life was given to this question. In 1881 Cape Colony was confined upon the north by the Orange river. The Bechuana territory, which lay beyond the river, was a sort of no man's land through which ran the trade routes to the north. It was evident that any Power which commanded the trade routes would command the unknown northern territory beyond. The London Convention of 1881 limited the westward extension of the Transvaal to a line east of the trade routes. Nevertheless the reconstituted Republic showed itself anxious to encroach by irregular overflow into native territories, and Mr Rhodes feared to see the extension of the British colonies permanently blocked by Dutch occupation. One of his first acts as a member of the Cape Assembly was to urge the appointment of a delimitation commission. He served in person on the commission, and obtained from the native chief Mankoroane, who claimed about half of Bechuanaland, a formal cession of his territories to the British Government of the Cape. The Cape Government refused to accept the offer; but as a result of Mr Rhodes's urgent representations, an Imperial Protectorate was, after much discussion, declared over Bechuanaland in 1884. The British flag was thus carried to the 22nd parallel. In the same year a second Convention was signed in London laying down definite frontiers on the eastern border of Bechuanaland within which the Transvaal undertook to confine itself. With the consent of Great Britain, Germany occupied almost at the same time the territory on the Atlantic coast which is now known as German South-West Africa. Mr Rhodes occupied the position of resident deputy commissioner in the new British territory towards the end of 1884. When he took up the duties of his office he found that, notwithstanding conventions to the contrary, a further determined attempt had been made on the part of the Dutch to overrun the border. The country had been practically seized by a Boer commando. An old Dutchman who knew the value of the position said privately to Mr Rhodes, "This is the key of South Africa." The question at issue was whether Great Britain or the Transvaal was to hold the key. It was a question about which at that time the British public knew nothing and cared nothing. Mr Rhodes made it his business to enlighten them. President Kruger, speaking for the Government of the Transvaal, professed to regard the Dutch commandoes as freebooters, and to be unable to control them. It devolved upon Great Britain to oblige them to evacuate the territory. As the result of Mr Rhodes's exertions the necessary step was taken. The Warren expedition of 1884 was sent out. In the presence of British troops upon the frontier President Kruger recovered his controlling power over the Transvaal burghers, and without any fighting the commandoes were withdrawn.

It was the first round in the long duel fought on the field of South Africa between Mr Rhodes, as the representative of British interests, and President Kruger, as the head of the militant Dutch party. The score on this occasion was to Mr Rhodes, and the entrance to the interior was secured. But the 22nd parallel was far short of the limits to which Mr Rhodes hoped to see British influence extend, and he feared lest Germany and the Transvaal might yet join hands in the native territory beyond, and bar his farther progress towards the north. The discovery of gold at Johannesburg in 1886, by adding to the wealth and importance of the Transvaal, gave substance to this fear.

The territory to the north of the 22nd parallel was at that time under the domination of Lobengula, king of the Matabele, a native potentate celebrated alike for his ability and for the despotic character of his rule. There were rumours of Dutch and German emissaries at the kraal of Lobengula, engaged in persuading that chief to cede certain portions of his territory. Portugal also was putting forward shadowy claims to the country. It was in these circumstances that Mr Rhodes conceived the idea of forming a British Chartered Company, which should occupy the territory for trading and mining purposes as far as the Zambezi, and bring the whole under the protection of Great Britain. The idea took shape in 1887, in which year Mr Rhodes's first emissaries were sent to Lobengula. The charter of the British South Africa Company was granted in October 1889. Between the two dates his conception of the possibilities to be achieved by the Company had expanded. Mr Rhodes no longer limited the sphere of his operations to the Zambezi, but, crossing the river at the back of the Portuguese settlement at its mouth, he obtained permission to extend the territories of the Chartered Company to the southern end of Lake Tanganyika, including within the sphere of its operations a British settlement already made upon Lake Nyasa. He hoped to go farther still, and to create a connected chain of British possessions through the continent which might eventually justify the description "Africa British from the Cape to Cairo." The treaty negotiated between Great Britain and Germany in 1890 extended the German sphere of influence from the East Coast to the frontier of the Congo Free State, and defeated this hope. But Mr Rhodes did not wholly renounce the idea. In 1892, when the question of the retention or abandonment of Uganda hung in the balance at home, he threw all the weight of his influence into the scale of retention, and undertook at his own personal expense to connect that territory by telegraph with British possessions in the south. In the following year, 1893, it was found inevitable to fight the Matabele, and a war, prosecuted with a success that is perhaps unique of its kind, placed the country entirely in British hands. The territory thus added to the British Empire covered an extent of 750,000 square miles, of which large portions consist of healthy uplands suitable for white colonization. From this time onwards through his very active life Mr Rhodes gave constant attention and encouragement to the development of British administration in the new territory, to the construction of roads, telegraphs, and railways, the laying out of towns, the introduction of good breeds of farming stock, the planting and draining of agricultural land, and the working of minerals, upon which the financial stability of the new protectorate mainly depended. The pioneer party who constructed the first road and founded the first British stations in the country received their orders to cross the frontier in the end of 1889. By the and of 1899, before the outbreak of the South African war, though the country had passed through the trial of a war, two native rebellions, and the scourge of rinderpest, it had become, under the name of Rhodesia, a well-settled province of the British Empire, with a white population of some 12,000 to 13,000 persons, already clamouring for the privileges of self-government.

The six years which followed the granting of the charter may be regarded as the most successful of a singularly successful life. In 1896, not many months after the granting of the charter, Mr Rhodes accepted the position of prime

minister of the Cape. He was maintained in power very largely by the Dutch vote, which he spared no pains to conciliate; and having the confidence of both political sections of the colony, he found himself practically in a position to play the part of benevolent despot in South Africa. He used the position well so far as the public was concerned. While his scheme of northern expansion was making the rapid progress which has been indicated, he did much to elevate and to enlarge the field of local politics. He frankly declared and worked for the policy of uniting British and Dutch interests in South Africa; he took a keen interest in local education. He also during this period carried through some important reforms in native policy. He had the courage to restrict the franchise, introducing an educational test and limiting the exercise of voting power to men enjoying an income equal to a labourer's wage—thus abolishing, without making any distinction of colour, the abuses of what was known as the "blanket" vote. Long before the passing of the Franchise Act Mr Rhodes had openly stated his opinion that in dealing with an entirely distinct people there was no alternative between receiving them on an equal footing as citizens or treating them as a subject race. He was not prepared to receive the black races of South Africa on equal terms as citizens with the white, and he accepted the, to him, logical conclusion that there must be class legislation. In his heart he had perhaps a suspicion that every man who denied this conclusion was either fool or knave. For his own part, having accepted it, he accepted it frankly, and made no attempt to conciliate the sentimental party with pretences.

But his native policy was far from being one of simple restriction. He liked the natives; he employed them by thousands in the mining industry, he kept native servants habitually about his person, he seemed to understand their peculiarities and was singularly successful in dealing with them. The first canon of his native policy was that liquor should be kept from them; the second, that they should be encouraged to labour, and guaranteed the full possession of their earnings; the third, that they should be educated in the practical arts of peace. He appreciated the full importance of raising their territorial condition from one of tribal to individual tenure; and while he protested against the absurdity of permitting the uncivilized Kaffre to vote on questions of highly civilized white policy, he believed in applying to the native for his own native affairs the principle of self-government. Of these views, some received practical embodiment in the much-disputed Act known as the Glen Grey Act of 1894. In this connexion it may also be noted that he was one of the warmest and most convinced supporters of Lovedale, the very successful missionary institution for the education of natives in South Africa.
